In process of time, the term rabbi was used with great latitude; being bestowed on those who were not actual teachers; and yet it always retained, ever since it had been appropriated to the learned, a relation to learning, and denoted that the person who enjoyed it, though not actually employed in teaching, was well qualified for the office. Rabban, as some have asserted, is not the name of a degree superior to rabbi, though it seems intended for heightening the signification, and may be understood to denote eminent or learned rabbi, but it was very seldom used. The title rabbanī, which we find to have been twice given to our Lord, (Mark, x. 51. John, xx. 16.) is rabban, with the addition of the suffix of the first person, and accommodated to the pronunciation of Judea. The use of the term rabban does not seem to have extended far beyond Palestine, as we may conclude from the following circumstances. Although the word rabbi is very common in the Syriac translation, the Greek ἱεροσολυμων is generally so rendered; yet in the only place where that translator introduces the word rabban, which is that quoted from John, he prefixes in Heb. i.e. in the dialect of Palestine, which was then so called, adding the explanation given by the evangelist, ἵνα ἢ τέχνη; which plainly shews that the word rabban was not Syriac. This is the more remarkable, as in the other passages, where the historian interprets, in the same manner, the word rabbi, adding (John, i. 38) "αὐτὸς ὁ Ἰησοῦς οἱ ἡγίασαν ὁ Ἰωάννης," that interpreter omits this explanatory clause as intended only for the Greek reader, and of no use to those who understand Syriac. In the passage in Mark, where rabbi occurs, as the evangelist had added no explanation, his interpreter has not thought it necessary to change their own word rabbi; thus regarding the difference in signification between the two words as unimportant, to which we may add, that the apostle John explains both by the same Greek word. It may be here observed that it was customary to enhance the import of a title by doubling it. Thus our Lord, speaking of the Pharisees, says, (Matt. xxiii. 7.) "they love to be called of men rabbi, rabbi." In this manner he was himself addrest by Judas, at the time when that disciple chose to assume the appearance of more than ordinary regard. (Mark, xiv. 45.) The title rabbi seems to have been used in the same manner. (Matt. vii. 21.) The words Jewish rabbi and Jewish doctor were commonly used synonymously. In Justin Martyr's dialogue with Trypho the Jew, the rabbis are always called ἱεροσολυμων. But some may object that this does not account for the application of the title to our Lord, as he did not derive his doctrine from any of those learned seminaries, frequented by such of the youth as were reckoned as the flower of the nation; the name doctor could not, with propriety, be applied to him. To this objection it may be replied, that as in Judea at that time they spoke not Greek, but a dialect of Chaldee, not differing considerably from that which is called Syriac, it is evident that the actual compulsion by which our Saviour was addressed, was rabbi, equivalent to the Greek ἱεροσολυμων. Besides, though the title rabbi could regularly be conferred only by those who had the superintendency of their schools, yet the people would be disposed to give the compulsion through courtesy, and on the presumption that it had been conferred, wherever they saw or supposed distinguished abilities in teaching; and this probably was the reason why it was given to John the Baptist. (John, iii. 26.) Moreover, in the Jewish state, a divine commission was conveyed to confer all sorts of dignities and honours, in an eminent manner; and thus superintended all ordinary rules and human distinctions. Accordingly, some of those who gave the title of rabbi to our Saviour, were willing, either sincerely or pretentiously, thus to account for their doing so. Thus Nicodemus affirms the reason why he saluted him rabbi (John, iii. 1. c.), although he knew that he had not been educated in human literature, and had not received from man any literary honours. Upon the whole we may remark, that the term ἱεροσολυμων may be fitly expressed, either by the English term doctor, or by the Syriac rabbi, which is now so much naturalized among us, that its meaning, as a Jewish title of literary honour, can hardly be miltaken. It must also be allowed, that the rabbi among the Jews of our Saviour's age, was a title in the highest degree respectable; and on that account it was interdicted by their master, even to the apostles themselves. Campbell's Seventh Preliminary Dissertation.

The modern rabbis are entitled to a considerable respect among the Jews; they have the first places in the synagogues; they determine all matters and controversies of religion, and very frequently pronounce upon civil affairs. They have even a power to excommunicate the disobedient.

They retain a vast number of superstitious traditions, from the writings of their predecessors; which they observe as scrupulously as they do the law of Moses.

The ancient rabbis were infinite dealers in allegories. Their writings are almost wholly allegorical, particularly their comments and interpretations of the scripture.

They had a great number of rules, and forms of interpreting and quoting, which some modern writers suppose to have been followed by the apostles, in their interpretation and quotation of the prophecies of the Old Testament, in the New. See QUOTATION.

RABBINICAL Character. See Hebrew.

RABBINICAL Hebrew. See Hebrew.

RABBINIST. A follower of the doctrine of the rabbis; a term used in contradistinction to Caraites.

Father Simon contends for Rabbanish, or Rabbanite, instead of Rabbinist; in effect, the former readings are apparently preferable to the latter; the word being derived from the Hebrew Rabbanim, which is the name of the sect, and which the Jews use to distinguish their doctors from those of the Caraites.

Rabbinist, then, signifies a Jewish doctor who adheres to the traditions of his fathers; not simply a rabbin or doctor; for the Caraites, who oppose those traditions, have their rabbins as well as the other Jews.

RABBIT, Cuniculus, in Zoology, a well-known animal of the hare kind, or the lepus cuniculus of Linnaeus, with a short tail and naked ears. In the wild state the colour of the fur is brown; but in a tame state it varies to a black, pied,
RABBIT.

Pied, and quite white; the eyes are of a fine red. In their wild state they inhabit the temperate and hot parts of Europe, and the hottest parts of Asia and Africa. See Lepus Cuniculus.

The female, or doe rabbit, goes with young thirty days, and then the kindled; and if the take not buck presently the lollas her month, or at least a fortnight, and often kills her young and eats them.

In England they begin to breed at a year old, but in some places much sooner; and they continue breeding very far from the time when they begin, four, five, six, or seven times a year being common with them. They have usually from four to eight in a litter, and hence it is that a small number at first will soon flock a whole warfare, if left to breed a little while undisturbed. The doe cannot fumble their young till they have been at buck again; this therefore is to be done presently, else there is a forint night of the time for the next brood, and the present brood also probably lost. When the buck goes to the doe, he always first beats and stamps very hard with his feet, and when he has copulated with her, he falls backwards, and lies, as it were, in a trance; in this rate it is easy to take him, but he soon recovers from it.

The buck-rabbits, like our bear-cats, will kill the young ones, if they can get at them; and the does in the warrens prevent this, by covering their flocks, or nests, with gravel or earth, which they clofe so artificially up with the hinder part of their bodies, that it is hard to find them out. They never fumble the young ones at any other time than early in the morning, and late at night; and always, for eight or ten days, close up the hole at the mouth of the nests, in this careful manner, when they go out. After this they begin to leave a small opening, which they increafe by degrees, till at length, when they are about three weeks old, the mouth of the hole is left wholly open, that they may go out; for they are at that time grown big enough to take care of themselves, and to feed on grafts.

People who keep rabbits tane for profit, breed them in hutchcs; but these must be kept very neat and clean, or they will soon be subject to diseases. Care must be taken also to keep the bucks and does apart till the latter have just kindled; then they are to be turned to the bucks again, and to remain with them till they fum and run from them.

The general direction for the chofing of tame rabbits is, to pick the largest and fairest; but the breeder should remem ber, that the fkins of the silver-haired ones fell better than any other. The food of the tame rabbits may be colewort and cabbage-leaves, carrots, parsnips, apple-rinds, green corn, and vetches, in the time of the year; also vine-leaves, grafs, fruits, oats, and oatmeal, milk-thistles, fow thistles, and the like: but with these most foods they must always have a proportionable quantity of the dry foods, as hay, bread, oats, bran, and the like, otherwife they will grow pot-bellied, and die. Bran and grains mixed together have been also found to be very good food. In winter they will eat hay, oats, and chaff; and these may be given three times a day; but when they eat green things, it must be observed, that they are not to drink at all, for it would throw them into a dropfly. At all other times, a very little drink ferves their turn, but that must always be fresh. When any green herbs or grafs are cut for their food, care must be taken that there is no hemlock among it; for though they will eat this greedily among other things, when offered to them, yet it is hidden poison to them.

Rabbits are subject to two principal inftirmities. First, the rot, which is cauofed by the giving them too large a quantity of greens, or from the giving them fresh gathered, with the dew or rain hanging in drops upon them. It is excefs of moifture that always caufes this fiale; the greens, therefore, are always to be given dry, and a fufficient quantity of hay, or other dry food, intermixed with them, to take up the abundant moifture of their juices. On this account, the very, belt food that can be given them is the least and fweetest hay that can be got, of which one load will ferve two hundred couples a year; and out of this flock of two hundred, two hundred may be eat in the family, two hundred fold to the markets, and a fufficient number kept in cafe of accidents.

The other general difeafe of these creatures is a fort of madness: this may be known by their wallowing and tumbling about with their heels upwards, and hopping in an odd manner into their boxes. This difternum is fuppofed to be owing to the ranknefs of their feeding; and the general cure is the keeping them low, and giving them the prickly herb, called tare-thifles, to eat.

The general computation of males and females is, that one buck rabbit will ferve for nine does; some allow ten to one buck; but thofe who go beyond this always fuffer for it in their breed.

The wild rabbits are to be taken either by small our dogs, or by Spaniards bred up to the sport; and the places of hunting thofe who ftraggle from their burrows is under clofe hedges or bulks, or among corn-fields and fresh farts. The owners ufe to coufe them with small greyhounds; and though they are feldom killed this way, yet they are driven back to their burrows, and are prevented from being a prey to others. The common method of taking them is by nets, called purfue-nets, and ferrets. The ferret is fent into the hole to force them out, and the purfue-net being spread over the hole, takes them as they come out. The ferret's mouth must be muffled, and then the rabbit gets no harm. For the more certain taking of them, it may not be improper to pitch up a hay-net or two, at a small distance from the burrows that are intended to be hunted: thus very few of the number that are attempted will efcape. The method by the dogs, called the lurcher and bumer, is alfo a very good one.

Some, who have no ferrets, fmock the rabbits out of their holes with burning brimfome and opiment. This certainly brings them out into the nets, but then it is a very troublesome and offensive method, and is very detrimental to the place, as no rabbit will for a long time afterwards come near the burrows, which have been fumed with thefie tinkel ing ingredients.

The teficle of a rabbit is a very good object for exa mineing the fiature of this part of generation in animals. The teficles of various animals are very variously com posed, but all, in general, of vefcles variously rolled and folded together; and even the human teficles are of the fame fort, being composed solely of rolls of vefcles, without any intermediate fubftance, only conflict of vefcles and their liquors. Phil. Trans. N° 52.

The fkins of rabbits are a great article of commerce, numbers being exported to China: the fur is of great ufe in the hat-manufactory.

RABBIT, in Agriculture, is sometimes employed as farming flock. It is sufficiently evident, however, that this is a defcription of farming flock that can only be attended to with advantage under particular favourable circumstances of soil and fitation.

Situation proper for Rabbits.—The practice of forming rabbit warrens, can only be beneficially introduced where the lands are not capable of affording crops of tolerable grain or grafs. The great uncertainty of this fort of husbandry
RABBIT.

hubbard renders it much more advantageous for the farmer to depend upon such crops, than on it. In hilly tracts of land, where the plough cannot be introduced, and where the soil is of such a light sandy porous nature, as to afford little or no grass for the pasturage of sheep, or in rocky situations, this system of management may take place with profit to the farmer.

And it has been observed by the author of the Rural Economy of Norfolk, that this sort of animal is there confined to the heaths, and the barren hills upon the coast. A level country is unfit for rabbit-warrens, but convenient for the plough; on the contrary, rabbits delight in the sides of sandy hills; which, where turn-vrill ploughing are not in use, are extremely inconvenient for tillage; and, when cultivated, are generally unproductive. For the rabbit, on level ground, finds it difficult to make its burrow; the excavated mould is all to be dragged upward to the surface; hence a piece of ground altogether level, can seldom be fenced successfully with rabbits; unless it be first laid up by art, at a great expense, into inequalities. While, on the contrary, against the side of a steep hill, the rabbit has no difficulty to encounter: the declivity affords him a ready vent for his mould; his work is all down hill; and, unless the soil be too stubborn, or too rocky, for the rabbits to work freely among, a broken hilly country may generally be fenced with advantage; provided a tolerable market for the carcasses can be had within reach. He thinks there are, perhaps, few sandy or other loose-foiled hills, which would not pay better in rabbit-warrens, than under any other course of husbandry that could be introduced on them. And it is afterwards flatted, in a minute, that on a considerable part of a farm which lies towards the coast, being hilly and very badly foiled,—more especially the tops and sides of the hills, which have always been full of rabbits in spite of all endeavours to destroy them,—the tenants last year (1782) applied for leave to convert this part, about ninety acres, into a rabbit-warren. Leave was given, and an allowance made them of half the estimated expense of raising a foild-wall fence round these ninety acres. He adds, that the fence was nearly finished, and the warren had, that year, turned outside beyond expectation; it was valued by one who ought to be the best judge of its worth, at forty pounds a year; which is nine shillings an acre. And that, as the part of a farm, these ninety acres were not worth five shillings an acre; at the then prevalent price of barley, they were not worth more than four shillings an acre. It is, therefore, observed, that for ten pounds a real improvement of twenty pounds a-year has been made and secured; for the warren will, through necessity, hereafter keep the fence in repair for his own advantage. He remarks, that the fence is made about four feet high, and three feet thick; faced with green-ford; and capped with furze, so as to project eight or ten inches over the face. Some of it was done for a filling rod; but the spring putting up, fourteen or fifteen pence a rod of seven yards was obliged to be given. And a neighbouring warrene, that winter, gave moneyness for the wall without the capping; which he does not mean to put on till the wall be thoroughly settled. This is very judicious; as several roads of that above-mentioned shot down in different places, as is often the case in such fort of work. It is further observed, that there are several patches in the vallies, and some on the tops of the hills which have usually been tilled. Some of these were last year (1781), and some of them ought to be every year, cultivated for the rabbits; thus, when the grazes gets foul or moffly it should be ploughed up; fallowed, lowing turnip-feed for present feed, (they will not let rape get up,) and to prepare the foil for barley and grafs-feed the ensuing year. Thus a regular succession of feedage might be kept up for the use of these animals.

And in the Rural Economy of Yorkshire it is stated, that at Dolby there are two pretty large warrens. At Lockton there is one now (the time of writing) planting. And there are other parts of these heights which might be profitably flocked with rabbits. In general, however, property is too much intermixed to admit of an improvement, which is singularly adapted to the nature of these high grounds. And, that in situations where the ground, as well as the soil, is suitable to rabbit-warrens, and where an extent of it, sufficiently large, can be collected together in one property, there is a very strong reason why it may be profitably focked with rabbits. It is added, that one of the warrens of this district contains eighteen hundred acres of surface; most of it covered with a black morendand foil; part of it a barren gravel; some little of it a thin lime-fone loam; not worth perhaps, on a par, for the common purposes of husbandry, a hilling an acre; nevertheless, these eighteen hundred acres are let, as a rabbit-warren, for three hundred pounds a-year. He will not pretend to say, that this warren is worth three hundred pounds a-year, nor affect that it is not worth a hilling an acre to a husbandman. If it be worth two hundred and fifty pounds, as a warren, and supposing it to be worth even two hillings an acre, as a farm, it will be sufficient evidence of the profitableness of rabbit-warrens, in proper situations.

And in speaking of the wolds, he observes, that the warrens are numerous, and some of them very extensive. Coldham warren is at present, he believes, the largest upon the wolds; and, probably, the most valuable warren in the island. The Coldham farm contains about nineteen hundred acres; and, speaking generally, it is all warren; not, however, wholly appropriated to rabbits, a flock of from fix to eight hundred sheep being kept within the warren walls; principally, however, on one side of the warren, away from the burrowing grounds. And this appears to be a practice peculiar to the wolds of Yorkshire and Lincolnshire, whose hills likewise abound much with rabbit-warrens, and where better foil is appropriated to rabbit-warrens, than is perhaps in any other part of the island. The Coldham warren, in point of foil, is most of it worth from ten to twelve hillings an acre; some of it fifteen or sixteen hillings. But the present bleakness of the situation renders it of little more than half the value. As these better parts become mossy, they are inclosed by a fod-wall, the surface pared and burnt, and the foil broken up for arable crops. Having afforded a succession of crops of corn, turnips, &c. they are now with grafs-feeds, and again thrown open to the rabbits and sheep. In 1783, there were about two hundred acres of this farm under the plough, besides some little flesy-walk which lay without the warren walls. The warren therefore, at that time, contained from fifteen to sixteen hundred acres; and, adjoining to Coldham, are two more considerable warrens; so that there are, perhaps, three or four thousand acres of tolerably good land, lying together, and appropriated principally to rabbits.

But it is remarked in respect to foil, that there is a disadvantage in stocking a rich foil with rabbits; a flufh of grafs, after a dry seazon, is found to produce a feouring; which sometimes carries off great numbers. With regard to the burrows on the high wolds, they are mostly on the sides of hills; at Coldham, principally in one deep valley; whose sides are steep; giving the rabbits great freedom in working. The foil, in this case, is about eight or ten inches deep, under this a chalky rubble, of some inches thick, lying on a chalk-fone rock. The burrows are in the sub-foil,
between the foil and the rock, and chiefly towards the tops of the hills. And thousands of daws build their nests in the burrows, to the great annoyance of the rabbits. But at Driffieldgrees, near Driffield, where there are two large warrens, the surface is a dead flat; nevertheless, the warrens are well stocked and productive; a proof that a flat surface may, in some cafes, be profitably flocked with rabbits. The soil, in this cafe, is a light land or gravelly loam, which is very proper for the purpose to which it is applied.

In some of the very southern districts, rabbits occupy the different sandy hillys, and many of the rocky wales; but there is nothing of any great importance in the management of them. Both the grey and black forts prevail in some instances. The writer of the Suffolk Report on Agriculture thinks, that this fort of flock is the nuisance of a county: it increases and flourishes in proportion to the size of the wales, and is, of course, productive in this county. From Horigham foeld, Athsdown, and other parts, very considerable quantities of rabbits are sent to be disposed of in London.

In some of the midland counties they are found to be sufficiently abundant upon the sandy parts of waste lands; in inclosed level land, it is thought that they are no better than vermin, and that though the commons be pretty generally inclosed, they must be in a great measure exterminated to make way for a better fort of flock; in inclosed land, they can only be kept with propriety, either in small warrens near the house, well fenced in, for family consumption; or on sandy or rocky precipices, impracticable to the plough, where they should also be fenced in. It is well known, that in the neighbourhood of commons abounding with them, great pains and expense are often used to fence the inclosed adjoining lands from their depredations. Rabbits are certainly a fort of flock unworthy of being cultivated, or bred in any considerable numbers, on inclosed and cultivated land; yet doubtless deserving considerable attention on impracticable sandy or rocky heaps, which may at the same time be planted; and when properly fenced in, and thus flocked, such land seems in a fyllem of the highest improvement of which it is capable.

In Cheshire many doubts have been entertained as to the advantages of encouraging the breed of rabbits, and many farmers are at utterly averse to them, that they would with the whole race to be entirely exterminated. Where land is inclosed, and applied to arable purposes, it seems agreed that by the injury they do to the fences, by the interfering with the cultivated land, and by the destroying of its produce, they are much more detrimental than profitable. It is, however, thought to be a question for consideration, whether, if a portion of weak land, or dry heath land, was set apart for a rabbit-warren, well fenced, and kept distinct for this purpose; it might not, in some situations, be more profitably employed in this than in any other manner.

By some it is supposed, that it may be occasionally necessary to restrain them, on account of their affluming fecundity; but that to attempt to exterminate them, if it were possible, could not be politic or advisable, as they furnish food for foxes, which would otherwise prey on game and poultry.

This fort of flock is frequently met with in many other districts on tracts and spots of similar kinds of barren and unincultivable sorts of land, and is probably the most convenient, appropriate, and beneficial description of any by which they can possibly be occupied and managed.

Stocking.—In the second of the above districts, it is stated, that in flocking a warren, whether the surface be flat or hilly, artificial burrows are made to reconcile the rabbits to the ground, and to preserve them from vermin, until they have time to make their own burrows. And that in making these burrows, an improvement has lately, it is observed, been hit upon. They are bored with an auger, of a diameter large enough to make a burrow of a sufficient width. In a level warren, these augers may, from time to time, be found useful in forming such holes. They, however, in most cafes, are capable of making burrows for themselves without any difficulty.

But in regard to flocking in Lincolnshire, according to the agricultural survey of that district, some of the warren lands are stocked in the proportion of three couple only to the acre; while in others, it is in a considerably larger proportion. And one buck or male rabbit is said to be there sufficient for one hundred does, or females; but this is certainly a much larger proportion of the latter fort, than is allowed in most other districts. On the strong warrens of Yorkshire, according to Mr. Marshall, one male is considered as sufficient for only nine or fourteen females, and the nearer they can be brought to that proportion, the greater the flock of young ones that may be expected, it being the nature or economy of the males to destroy their young, especially when the proportional number is too great.

Fencing.—The fencing in these situations is sod-wall, capped with furze, or of late with full straw, forming a kind of thatch. And it is supposed, that a good and useful fence would be found admirable in this situation. The warrens near Driffield are fenced with palings; an expensive fence in the outset, and always under repairs. A brook, though ever so deep, is found to be insufficient as a fence against rabbits; one side of Driffield upwards is bordered by a brook; but it is nevertheless fenced with palings. When the rabbits can evade this, they readily swim the brook. The necessity of good fences is of course sufficiently evident in this view, as well as that of preserving them from the destruction of vermin, and birds of prey, such as eagles, kite, &c. which are taken in steel traps, placed on elevated mounds of earth, where they delight to sit. It is this kind of fencing and coping, or kidding the top, together with food in water, nets, traps, and other things for taking them, with charcoal for drying the skins, warreners’ men for killing and carrying, horfes for carrying them to market, &c. which constitute the great expense of this fort of management.

Different Breeds.—There are many different breeds or varieties of these animals; but those that are employed as flock for warrens are the common grey and silver-grey breeds: the former of which is found to be considerably more hardy and much better for the purposes of food; but the latter has greatly the advantage in the value of the skin. In the above warrens, till lately the common grey rabbit, probably the native wild rabbit of the island, was the only species. At present, the silver-haired rabbit is sought after, and has, within the few last years, been introduced into most warrens. The skin of the grey rabbit is cut; that is, the wool is pared off the pelt, as a material of hats; whereas, that of the silver-haired rabbit is dried as fur; which, the writer understands, goes principally to the East Indies. The colour is a black ground, thickly intermixed with fingle white hairs. The skins of this variety fall for about four shillings a dozen more than those of the common fort; a sufficient inducement for propagating it in preference to the grey fur in most cafes. If the white forts could be introduced they might be full more valuable.

Management, Expenses, Profit, &c.—This is a fort of flock that on the whole only requires a slight attention; it is, however, necessary to supply the rabbits with additional food in the winter season, when the weather is severe, such
RABBIT.

such as fine green hay, fainfain, clover, turnips, and others of the fame fort, which muff be diftributed over the warrens. It is fuppoled that turnips anfwer the beef in deep foows, as the rabbits can difcover them by the fecnt. This fort of food is given in the quantity of two or three large cartfuls to a thoufand couple per day, and one load of hay in the fame time during a storm. It is likewise ofte times the prac-
tice to diftribute billets of new cut afh-bofhood, gorfe or whins, and other fimilar woods in the warrens, the bark and other parts of which is eaten, by which the proportion of hay is leaffened in a confiderable degree. In great foows, it is neceffary to clear them away from the ditches or fences, to prevent the rabbits from getting over them.

It may be obferved, that the rabbit is a fort of flock that begins to breed at an early age, as at eight, ten, or twelve months, going only about thirty days with young, the young being a little more than three weeks old before they appear from the burrows, during which time they are fucked twice in the day by the mother. It is therefore evident, that they may breed three or four times in the course of the year under good keep, as the does take buck almost immediately after producing their young. In warrens that are inclofed, it is however faid, that they seldom breed more than two or three times in the year. The annual produce per acre, is moftly estimated at from three or four, to eight or ten couple, yielding a profit of from eight, ten, or even fifteen fhillings, where they are conducted under a good fystem of management. And the produce is, as has been fecn, the largest on new lands; however, much of the profit muft always depend on fituation, fo 28 to be near good markets.

These animals are in what is termed feafon from the end of October to the beginning of January, in which period the beef skins are produced; of coife a large pro-
portion of them is killed in this fhort time. The farmer often fultains great losfs in what by the purchafers are called half skins, quarter skins, and racks, fifteen of which are only confidered as a whole skin. The rabbits are difpofed of by the hundred, fix foore couple being confidered as an hundred.

The following statements are given in the Agricultural Survey of Lincolnshire, on this fort of management. On the authority of Mr. Chaplin, it is flated that on 1000 acres it is fair to kill 2000 couple, which are fold by the hundred, as above; which have fold at 10l. on an average of ten years; 2l. a year; killing and looking after, 60l. for 1000 acres. And on the warrens betwixt Gayton and Tathwell, filver skins have been from 15l. even to 25l. a dozen; but the common grey rabbit is fo much harder, that if a warren be focked with both, there will, in a few years, be nothing but greyfs. It is added, that from Louth to Caftor, 18 miles, 10 of them are warrens, chiefly filver; rent 2l. to 3l. per acre. They plough a part every year for corn and turnips; and laying down again with feed, let down the fences for the rabbits to enter. Warrens are reckoned profitable, fo that fome fortunes have been made on them. It is further flated, that in point of skins, thofe bred about May-day undergo no change from their white colour, but from a white rack become a whole skin; bred at Lady-day, become black; in June, white; in July, black; in November, white again; then in full feafon, as the carcafes are alfo. The skins ought to have thofe colours on the infide, when flayed, or stripped off from the rabbits. The writer further flates, that from 250 acres of land, that were fainfain worn out, and planted with rabbits, the following was the account many years ago; but all prices, rent, &c. &c. are calculated at the prezent rates; and it is to be noted, that the ground being thus new to rabbits was much more productive than old warren land is found to be, as they breed much better on fuch new than on old land. Used to kill about 2000 couple; flock left about 500 couple. Sod banks that collt, thirty-five years ago, 1s. 2d. a rood of seven yards, would now collt 2s. for the furze, and 2s. 6d. for going, now doubled. Banks will laff about seven years, in a middling way; from three to twenty; want facing once in feven years, at half the firft expence; want capping in three years with the furze. Laying on, or capping, 3d. per rood now. It was then reckoned that 250 acres would clear 100l., besides rent, which then was 1s. an acre. Fencing annually half a mile 800 yards 133 roods at 1s., 6l. 13s.; for facing furze, a kidd will do a yard; 2l. 5s. a year. There were other rates, it is 15l. 16l. 4d. per annum. A warrener 35l., a cow, fuel, and house: in all 40l. Extra labour, killing 18s. a-week for fourteen weeks, 1l. 8s. Also for a month 18s. a-week, 3l. In all 18l. Besides nets and thread, at 2s. 6d. each; laft new; 2l. per year; would be 11s. 6d. Traps 5s. a-year. The men who kill will carry. Four hores for fix weeks, 1l. 4s. a-week, 7l. 4s. Charcoal for drying skins, 5l. A perfon to order skins, that is, clear from fat, and drying, five weeks; a useful woman will do it, 1l. Winter food (after three days now they muft be ferved) cannot be lefs than 10l. a year on 250 acres.

Recapitulation.

But it is, notwithstanding this statement, fuggfeted, that if he had a warren of his own, he would plough it up for corn, &c. thinking tillage now more profitable than rabbits. And the author adds, that at Partney fair, meeting with Mr. Grant of Withke, and confulting with him upon warrens, he informed him that a common flock in winter was three couple per acre, and the produce five or fix couple.
RABBIT.

couple killed; that killing, carrying, &c. might amount to something more than 15. an acre: the fort fiber spring, which will not do well in other counties, where they have been tried. He has now 1000 acres of warren, and upon 1000 acres the flock is 2600, and kill 5000 couple annually. New land is the most productive. On such a warren, the rabbits must have two loads of hay a day in a form, or two or three large waggon loads a day of turnips. The warreneer has 20l. a-year, and two cows; the killers 8l. or 9l. a-week, and board for ten weeks. Silver skins now are 10l. a dozen; have been 15l. to 15s. Fences 60 a-year; no crofts ones; no buildings. The immense occupation of Mr. Grant and his sons, being much the most considerable in the county, with the circumstance of making an ample fortune, made him d.ious of seeing him. It is added, that 20 years ago, Dr. Hay had a warren of 12 or 1300 acres; and the rent of the farm including it, 300l. a-year, which rent has been doubled by ploughing. And Mr. Keirn observed, that the community received next to nothing from warrens; which is probably the case, as has been seen above, where the land is capable of being managed under the plough, or the system of gráfs.

And the calculation of Mr. Parkinon, of a warren of 700 acres under rabbits, in the same district, stands thus: rent 5l.; standing flock 2000 couple of silver hair, valued to the incoming tenant at 21. 6d. a couple ten years ago, and demanding a capital of 1400l.; and carefully typed to catch all extra bucks, to as to leave only one-fourth of the total number of bucks.

Take the average of the two, that is, silver hair of the Wolds, and greys of Lincoln Heath, it will be on a medium

Or about 10s. 10d. an acre. And add to these, 550 sheep, kept by a course of tillage; that is, ploughing up 50 acres annually for paring and burning for turnips; then spring corn and feeds, which feeds sheep-fed one year, and thrown open to the rabbits: the sheep at 2d. per week for 25 weeks, will amount to 72l. 10s. This is inferior to the common produce of sheep; but the rabbits will demand hay, &c. to the amount of the difference; and also a team of horses must be kept for the cultivation of 100 acres of land, and carrying the rabbits to market. Hence,

The 50 acres of corn will be consumed by

the horses, and master's and warrener's cows, &c. - - - 447 10 0

It is noticed, that as the family is maintained out of the farm, the intereft of the capital of about 1400l. is not charged, because the intereft would be only 70l. per year, when they are maintained out of the farm, with a profit of 294l. 3s. 10d.

It is flated by the writer of the above agricultural survey, that the warren of North Ormby, occupied by the late Mr. A. d. f. ell, is supposed to be one of the best managed in the country. The rabbits chiefly consist of silver-greys; the land of the yearly value from 2. 6d. to 8s., and some little of it 10s. the statute acre. The occupier was of opinion, that lately his warren lands would have paid him better, had they been applied to the purpose of growing corn, and graft feeds for keeping sheep. The rabbit produce is supposed to be from 8l. to 10s. in some particular years they have paid from 15l. to 21l. an acre; but to obtain any extraordinary profit, very great care must be taken in killing the many different kinds of vermin which depredate, and, without the utmost vigilance, will

It is noticed, that as the family is maintained out of the farm, the interest of the capital of about 1400l. is not charged, because the interest would be only 70l. per year, when they are maintained out of the farm, with a profit of 294l. 3s. 10d.
RABBIT.

will quite depopulate the warrens. A considerable expense also attends the necessity there is for night-watchers, to protect them from the infinitely worse vermin, the poachers. With him the silver-grey skins have been sold from 8½ d. to 15 d. and 16 d. per skin; the last two years they have only brought from 10 d. to 11 d. per skin; but to obtain even these prices, they must be what is called full seamoned, whole skins, and of the choicest colours, with respect to which the fashion varies very greatly. The carcases, of late years, have not averaged net into pocket more than 4 d. per couple, after the expense of drying them, and by means of light diligence carts, having them carried to markets 30, and sometimes more than 60, miles to obtain even that sum. This inconvenience is occasioned partly by its being necessary to kill eight or ten parts of a year's slaughter in to short a time, as between the second week in November and Christmas, on account of their skins being then only in full prime, and as they are also very soon subject to become putrid, much more so than hares; and their being obliged to be packed close together, very greatly increases the mischief.

The estimate of the warren on the estate at Thorneyway of 1700 acres, as given by the tenant Mr. Holdgate, with the silver fort of rabbits, is this:

<table>
<thead>
<tr>

Or about 22l. per cent. (the 5 per cent. included) on capital employed. This the writer observes is very great, reckoned on the capital, but small reckoned on rent, as it amounts to only half a rent. But suppose the gross produce of 1500, which he takes to be nearer the fact; then the account will stand thus:

or 45 per cent. on the capital.

But it is supposed that, in whatever way it is taken, it explains the reason of so many of these nuisances remaining. The investment of a small capital affords a profit or interest that nothing else will, and of course the proprietor will be sure never to convert them to better use. But, it is asked, what lays the public interest? Here are only 200l. expenses to 600l. rent, what is the population, the industry, the improvement! The landlord gets the lowest of rents, the tenant makes a good profit, they divide all, and the rest of the world is little or no better for them.

Rabbit-warrens are met with in most other districts of the kingdom, both towards the southern and northern parts of it; but more abundantly in those of the north. In the south they have in most places been got quit of by any tolerable fort of land which is capable of affording any other better kind of useful produce, but in some parts of the north they fill occupy spaces of ground which are of a good quality, and which might be converted to better purposes with great advantage to the proprietors, as well as farmers. Warrens of this nature, in some cafes, in both these situations, however, still continue to be well flocked, and in the latter, are in particular instances of pretty considerable extent.

In Cheshire, the principal rabbit-warrens are on Delamere forest, though on several of the heaths and sand-hills these animals are frequently met with, but not in such numbers together as to constitute warrens.

In the north riding of Yorkshire, also, a few rabbit-warrens are met with on the detached moors, as well as on the skirts of the higher moors; but they are not so extensive as to make them an object of much attention. The kind of rabbits here are mostly the common grey, with the exception of the flock on a warren at Nappa, in Wenley-dale, of about one hundred and fifty or two hundred acres, which consists of silver-greys, and is the only warren which is known, in this district, to be entirely flocked with this fort: they are flinted to have been brought some years since from a warren in the above noticed district of Lincolnshire, to which they had been originally introduced from Ireland.

The skins of this kind of rabbits are supposed to be worth double those of the grey; they are not used for felts, as the last, but dressed as furs, and ultimately exported in that state for the China market, where they are worn by the principal people; an use which has been already noticed and considered in regard to the demand which it creates.

But in the northern parts of Lancashire, warrens of this kind are more frequent. At Rosall-hall, in the tract called the Fild, one of great extent has existed for a very great length of time; but the present proprietor, B. F. Hilketh, esq., has, with great propriety, lately reduced it very considerably, by taking two large fine farms from it, so that it now consists only of about a hundred acres of the most sandy barren part.

This warren formerly supplied a great number of rabbits for sale in the markets and hat manufactories of the neighbourhood, and of course became a source of profit to the owner, though the management was very imperfect. The farms taken from it will, however, become far more advantageous to him.

The flock here was formerly of the grey rabbit kind, and it is still the fame on the warren which remains, which is however far from being sufficiently flocked.

There was formerly no fort of green food ever cultivated for this fort of flock; nor has it been yet attempted on the present warren, but the proprietor intends to have it done in an effectual manner. Nor have the rabbits ever been fed in the winter season with either hay, bark, or any other fort of
of food; their being so near to the sea-coast perhaps renders it unnecessary.

The only mode of taking the rabbits here has hitherto been in nets, by what is termed running them by means of dogs.

At Heysham the Rev. Mr. Clarkson has a tract of coarse flinty land above his house, of about twenty acres, which has a great number of grey rabbits in it, and is well suited for a rabbit-warren, as it is incapable of being converted to any better purpose on account of the severity of the west winds, and the effects of the sea-spray thrown up by them, as well as its rocky, whiny nature.

The principal rabbit-warrens in this county are, however, those in the sandy tracts in the south and north ends of the isle of Walney, and in the neck of land from which it seems to have been separated. The rabbit-warren at the north end of this little island occupies a considerable space of ground of this barren sandy quality, as well as that at the southern point. The former is flocked wholly with rabbits of the grey kind, this fort being in great demand. There is much expense attending these warrens in many cafes.

The expense of flocking in order to keep them up is sometimes very considerable. In this instance the farmer has upwards of two miles of dike fence composed of sod and flint to keep up and in repair, which costs from five to six shillings the rod of seven yards. The expense of a man constantly to look after the rabbits, and keep the dike fences in proper order and repair. That of the purchase of the traps or types, which cost 5l. a-piece, and eighteen are required; but they last long, and cost little in repairs.

The providing net and dogs, which is annually about 10l.

The charge of taking the rabbits to Ulverston, twice in the week, during ten weeks, which is 5l. each time. The sale of rabbits is annually from one hundred and fifty couples upwards, at the rate of 2s. 6d. each couple. They are usually sold to Lyons of Preston, who takes the charge of them after they have been delivered at the above-named place.

Not any sort of dry or green food is ever given to the rabbits in this warren during the winter season; but there is not any snow, and very little frost taking place; in consequence of the situation being so surrounded by the sea.

The warren at the south end of the same little island is of similar extent, and exactly under the same fort of management; but it is said to be earlier, by a month at least, in the breeding of the rabbits, and the quality of their fur; which is supposed to arise from its being more fully exposed to the influence of the morning sun, in which the rabbit delights, and by which it is greatly benefited.

The rabbits are here likewise afforded to fall for a higher price, as 3l. the couple, than in the warren at the north end of it.

The rabbit-warren at Sand Scree is another farm of this fort in this neighbourhood, under similar regulations, but somewhat smaller than those in the isle of Walney; and there is a full smaller one attached to a farm at Rosanhead, the property of Miles Sandy, esq., of Greythwaite, which is conducted in much the same manner, and with the same results as in the above case.

It may be noticed that this fort of flock is mostly taken by nets or traps, let in the form of a fold between the places where they run, and thence where they feed, the rabbits being hunted into them as they return from feeding. But the wold warreners, Mr. Marshall says, have three ways of catching their rabbits: with fold-nets, with spring-nets, and with "types," a species of trap. The fold-nets are let about midnight, between the burrows and the feeding-grounds; the rabbits being driven in with dogs, and kept inclosed in the fold until morning. But the spring-net, when used, is, he believes, generally laid round a hay-flack, or other place, where rabbits collect in numbers. It is added that the trap is a more modern invention. It consists of a large pit or cleft, formed within the ground, and covered in with a floor: or with one large falling door, having a small trap-door towards its centre, into which the rabbits are led by a narrow mace. And this trap, on its first introduction, was set mostly by a hay-flack; but being, at that time, the chief winter food of rabbits; or on the outside of the warren wall, where rabbits were observed to scratch much, in order to make their escape. Since the cultivation of turnips, as a winter food for this species of flock, has become a practice, the situation of the trap has been changed. Traps being cultivated in an inclosure within the warren, a trap is placed within the wall of this inclosure. For a night or two, the mace is left open, and the trap kept covered (with a board or triangular rail), in order to give the rabbits the requisite haunt of the turnips: which having got, the trap is barred, and the required number taken. He adds, that in emptying the cleft, the rabbits are pierced; those which are fat, and in season, are slaughtered; those which are lean, or out of condition, are turned upon the turnips to improve. And that, at the close of the season, the bucks and doe are killed, in a similar way; the bucks are slaughtered, the does turned loose to breed. Mr. Marshall also remarks, that great caution is requisite in the use of these traps. If too many rabbits be admitted at once, and the cleft be kept close covered only for a few hours, suffocating and inordinate heat takes place, and the carcases, at least, are spoiled. Many thousand carcases have been wasted through these means. The traps are therefore watched; and when the required number is caught, the mace is flapped, or the trap covered in a proper manner.

And it is observed, that some notion may be formed of the produce of the wold warrens, from the great numbers which are frequently slaughtered at once; five or six hundred couple having not infrequently been slaughtered in one night: and, it is said, that when the two Driffield warrens lay together, there was once an influence of fifteen hundred couple being killed at one time.

There is often much inconvenience in this fort of flock, from their getting out of their inclosures, and destroying the young corn-crops, new turnips, young turnips, and the quick hedges as well as young plantations of apple-trees that may be in the neighbourhood. This forms a material objection to this fort of flock by the farmer.

Tame Rabbits.—In respect to breeding and rearing tame rabbits with the view of profit, those who are engaged in the business perform it in hutches, which must be kept very neat and clean, otherwise the rabbits will be subject to disease. Care must be taken also to keep the bucket and does apart, till the latter have just kindled, then they are to be turned to the bucks again, and to remain with them till they fatten and run from them.

And the general direction for the keeping of tame rabbits, is to pick the largest and fittest; but the breeder should remember, that the fawns of the silver-haired and white fort saw better than any other. The food of the tame rabbits may be coles and cabbage-leaves, carrots, parsnips, green corn, and vetches in the time of year; also parsley, grays, green leaves, milk, and low-thistles, and other similar plants, but with their man food they must constantly have a proportionable quantity of dry food, as hay, bread, oats, bran, and other similar matters, otherwise they grow pot-bellied, and die. Bran and grain mixed together have been found to
RABBIT.

to be very good food. In winter they eat hay, oats, and chaff, and these may be given them three times a day; but when they eat green things, it must be observed that they are not to drink at all, as it throws them into a droopy. At all other times a very little drink serves, but it should always be fresh. When any green herbs or grasses are cut for their food, care must be taken that there is no hemlock among it, for, though they will eat this greedily among other things, when offered to them, it is a sudden poison to them. In this mode of breeding, one male to eight or ten females is sufficient.

It is remarkable, that the author of the Treatise on Agriculture and Gardening, has bred these animals with much success and ornamental effect in a small artificial warren, or a lawn in the garden, made in the following manner. "Pare off the turf of a circle, about forty feet diameter, and lay it on the outside; then dig a ditch within this circle, the outside perpendicular, the inner sloping, and throw earth sufficient into the middle to form a little hill, two or three feet higher than the level of the lawn; the rest must be carried away. Then lay down the turf on the hill, and beat it well to settle. The ditch at bottom should be about three feet wide, and three and a half deep, with two or three drains at the bottom, covered with an iron grate, or a stone with holes, to carry off the rainy rains, in order to keep the rabbits dry. In the outside bank should be fix axles, the fides and top supported, either by boards or brick-work, to give the rabbits their dry food in; by their different situations, some will always be dry; fix boxes, or old tea-chefts, let into the bank, will do very well. If the ground be very light, the outside circle should have a wall built round it, or some stones driven into the ground, and boards or hurdles nailed to them, within a foot of the bottom, to prevent the bank from falling in. The entrance must be either by a board to turn occasionally across the ditch, or by a ladder. The turf being setted, and the grasses beginning to grow, turn in the rabbits, and they will immediately go to work to make themselves burrows in the fides, and in the hill. By way of inducing them rather to build in the sides, to keep the turf the nearer, make a score of holes about a foot deep, and they will fill them to their own mind; and if there be a brick-wall round it, it should be built on pillars, with an arch from each, to leave a vacancy for a burrow." But there is, he says, another way that may be practised, which is, "to dig the ditch only about two feet deep, which will yield about earth enough to make the hill; put some pales, about a foot high, on the outside, for that will be a sufficient height to keep the rabbits in. Feed them as other tame rabbits are fed; and in wet weather sprinkle saw-dust at the bottom, by which means the quantity of manure will be increased; once a week is often enough to take it away; the quantity will be surprising, nor will the smell be in the least offensive, even though it be quite close to the house. In a very large lawn, two or three of these hills, with the rabbits feeding on the tops, will not be unpleasing objects. If the bucks happen to be mischievous in killing the young ones, they must be chained in an alcove; or else have their liberty as in a warren. After a great snow they will want some affluence early next morning; because the ditch will be nearly filled, and perhaps the alcove, where the hay is, will be blocked up." He adds, that "it is a great improvement to cultivate the young bucks, and keep them till they are full grown, before you kill them; the flesh will be amazingly finer, whiter, and tenderer. But then it will be best to take them away, and keep them in another warren, left they should be too numerous, and disturb the breeding does; or else have a few hutches in the alcove to fatten them in."

It is suggested, that "as oil-cakes are found of great use in fattening cattle, it is probable they would be useful in fattening rabbits; and it is ascertained, that some of the oil mixed with the pollard or buck-wheat, is cheaper than the cakes; but having never made the experiment, he cannot ascertain its superior advantages."

In this mode, attention should be had to the breeding of these. For of rabbits whose skins are in the greatest effect with the furriers and hatters. These skins are generally of more value than the flesh, especially in the winter, against which time contrive to have the greatest quantity of these fattened bucks.

Profs.—It is remarked, in respect to profit in this way, that where does are kept in hutches, they are supposed to breed six times a-year, and only five young ones are left to each, which is thirty from each doe; but as these are in a more natural way, and the young ones difficult to be gotten at, let us suppose about thirty-six to be produced from each doe, reckoning only seven-pence for each; there is a guinea profit from each doe; as the additional value of the skins in winter, and the dung, will more than pay the expense of food and attendance on them. And it is quite necessary that those who keep many rabbits in this way, should cultivate some lucern, parley, and carrots, as no other vegetables are such proper food for them as these; they should also be fed upon some of the best upland par-ture-hay; for if it be coarse, so far from eating, they will waste it. Lucern hay is very proper for them in these cafes.

In some districts very considerable profits and advantages are derived from the breeding and keeping of white tame rabbits. The skins of this sort having lately been much employed in trimmings, have sold at a much higher price than those of the common kinds. Their dung is also found of very great utility in the cultivation of large farms.

Difficul.—When kept in this way, rabbits are subject to several diseases, as the rot, which is caused by the giving them too large a quantity of green food, or the giving it fresh gathered, with the dew or rain hanging in drops upon it, as it is over-moisture that always causes the disease; the green food should, therefore, always be given dry, and a sufficient quantity of hay, or other dry food, in-termixed with it, to counteract the bad effects of it. And a fort of madness often feizes them: this may be known by their tumbling about; their heels upwards, and hopping in an odd manner into the boxes. This distemper is supposed to be owing to the rankness of their feeding: and the general cure is the keeping them low, and giving them the prickly herb called tare-thistle to eat as much as possible. They are also subject to a fort of scabby eruption, which is seldom removed. Thee should, however, be directly separated from the rest of the flock.

It is noticed that the profit in this mode of management cannot, however, be well ascertained, as much will depend on the care which is taken in the feeding, and other management.

RABBIT-Warren, the place where these animals breed and rear their young. The land for this purpose should be of a light sandy quality, and it is best to have a hilly situation, with a funny exposure, being well inclosed by means of lod-walls, or palings-fences; any sort of waste, craggy, or rocky land, on which nothing else can be cultivated, answers very well for this purpose. See RABBIT.
RAB

RABBIT-Warren Farm, that fort which is chiefly managed under the rabbit system. These forts of farms are now much less common than formerly, but in some instances, as has been seen, they afford the best and most advantageous means by which lands can be turned to any account in the way of cultivation. They, however, in most cases require no little capital, exertion, and attention, to manage them in the best and most profitable methods. See RABBIT.

RABBIT Manure, that which is collected from the dung of those animals, and which is said to be very valuable. See MANURE.

It is found beneficial in different modes of application, as by being intimately mixed and blended with the manure of the soil or mould in arable lands, and by being thrown by the hand, only over the surface of it, in the way of a top-dressing, when they are in a state of crop. When used in this last manner, it is likewise highly advantageous on most sorts of grass land; and in both these cases of top-dressing with it, there is a very quick and powerful state of vegetation produced in the crops, which can hardly be gained in any other way. See QUICK MANURE, and TOP-DRESSING.

In Oxfordshire, Mr. Fane has raised a small building for keeping rabbits in hutches, for the sake of the manure; he is said to have some hundreds, and to meditate the erection of a second building for keeping double the number; the present quantity makes a load of manure in the course of the week; and as two loads manure an acre, they are the means of fully dressing twenty-six acres annually: it is not conceived by him that they produce any other profit, nor is it necessary; for to be able to sell too much food at home, and pay attendance, the profit of manuring such a breadth of land, it is supposed, must be considerable. Three dozen of rabbits in the week are mostly sent to the London market during the season in which they can be used.

This is a sort of dung or manure, which has yet been but little subjected to chemical examination, concomitantly its real properties, or constituent principles, are very imperfectly known or understood; it would appear, however, from the effects which it produces, that it may be employed with the most advantage, when laid upon the land, in its more raw, crude, or fresh state, before it has undergone much decomposition by the process of fermentation or putrefaction. It has, perhaps, never yet been kept dry and reduced into a powdery condition, so as to be put in along with the seed, in the manner of rape-dust, though it seems probable that it would go farther, and be more beneficial, in some cases, if used in this way. See DUNG.

RABCHORADO, in Ornithology, the name of an American bird, described by Nieremberg with many fabulous circumstances. All that seems certainly known is, that its tail is very remarkably forked.

RABDA, in Geography, a town of Arabia, in the province of Yemen; 30 miles N.W. of Sana.

RABDIUM, in Ancient Geography, Tur-Rabdun, a town of Asia, upon a mountain, at some distance from the Tigris, south of Tigranocerta, and east of Nisibis.

RABDOIDES. See RABDOIDES.

RABDOLOGY. See RHABDOLOGY.

RABDOMANCY. See RHABDOMANCY.

RABEOBA, a name given by some to the roots of the flammula major.

RABELAIS, Francis, in Biography, was born about the end of the fifteenth century at Chinon, in Touraine. At an early period he entered himself among the Cordeliers, and became well skilled in the learned languages, and the literature of the age. He acquired a good share of popularity as a preacher; and what he gained by his sermons, he expended in the purchase of a small library. His private life was not so exemplary as his public discourses were edifying; and for some misconduct, which caused scandal in the monastary, he was imprisoned in his cloister. By his wit and facetiousness he obtained his liberation, with the pope's permission to quit his order, and remove to that of St. Benedict. Not being able, however, to bear any kind of restraint, he laid aside his religious habit, and, in 1530, went to Montpellier to study medicine. After some time he repaired to Lyons, where he printed a collection of pieces of Hippocrates and Galen. Here he likewise published several other works, among which were some of the books of his History of Pantagruel, which gave him to distinguish a place among burlesque writers. In 1535 he went to Paris, and waited on cardinal John du Bellay, to whom he had been known when they resided in the same convent; and he now made himself so agreeable to his old friend, that he was taken into his house in the several capacities of physician, reader, librarian, and steward. Du Bellay, in the following year, going out as ambassador to the court of Rome, took Rabelais with him, where his wit so much interested the pope and cardinals, that he very readily obtained a full absolution for the crime of apocryphy. In 1537 he took his doctor's degree in physic at Montpellier; and returning to Paris soon after, his friend the cardinal presented him with a prebend in the chapter of St. Maur. He was afterwards made the cure of Meudon, which office he held from 1545 to his death, in 1553, being, according to one of his biographers, in the 63d, and according to another, in the 70th year of his age. His Pantagruel, which was finished about the time that he accepted the cure of Meudon, brought upon him the hostility of the monks, whom he had severely fatirized, and who procured its condemnation by the Sorbonne and the parliament; but it caused his company to be much sought after, as the wittiest writer of his time. The want of decency was closely pardoned at that period, and Rabelais had some estimable qualities, and polished expansive and various erudition, with a ready elocution, and an inexhaustible store of ludicrous ideas. "The Pantagruel and Gargantua of Rabelais," says a critic, "are to be regarded as comic fates, often乘tinged, under a whimsical extravagance, attacks upon follies which it would not have been safe seriously to expose. It is in vain, however, that commentators have attempted to find out the meaning in much that is mere ribaldry and nonsense, and even to discover real history veiled in the allegory of burlesque, where the author meant nothing more than to make his reader laugh or wonder. His fates, where it is intelligible, is often just and ingenious; but the obscurity of his language, and eccentricity of his conceptions, render the perusal of his works, to a modern at least, rather a talk than an amusement." The most complete editions of his works is that published in Holland, in 5 vols. 8vo., 1715, with notes by Duchat; and that at Amsterdam, in 3 vols. 4to., 1741, with plates by Picart. The letters of Rabelais were published in an octavo volume, with notes by St. Martin. The memory of Rabelais is perpetuated in the medical school of Montpellier, where bachelors are inducted with a scarlet robe, said to have been the very robe which wit himself wore.

RABELHORST, in Geography, a town of the duchy of Holstein; 5 miles W.N.W. of Cifmar.

RABENAU, a town of Saxony, in the margraviate of Meifen;
RABNECK, a town of Bavaria, in the bishopric of Bamberg; 3 miles S.W. of Weifenfeld.

RABENER, Theophilus William, in Biography, a celebrated German writer, was the son of an advocate at Leipfie, and born at Wachau in 1714. He was educated at home, by tutors employed for the purpose; but when he was 14 years of age, he was sent to the college of Meissen, where he had for fellow-students Graber, Gartner, and Geller, with whom, and particularly with the last, he formed a friendship which continued through life. In 1735 he went to the university of Leipfie, where he applied himself chiefly to the study of juridic prudence, without entirely neglecting the Muses. In 1741, professor Schwabe having begun a journal in the German language, entitled "Amusements of Reason and Wit," Rabener became one of his principal coadjutors, and continued to assist him by his contributions till the year 1744. He is chiefly known as a writer in the first volume, by a humorous piece entitled "Proofs of the Necesity of employing Rhyme in German Poetry." This periodical work was, for some time, carried on with spirit and success; but at length it became degraded by literary disputes, which finally put an end to it; and another was established, under the title of "Contributions of Bremen." The writers engaged in this were all the most celebrated persons who flourished at that period, among whom were Gartner, Schmidt, and Rabener, to whom were united Gellert, Klopotock, and others. The Journal of Bremen forms an epoch in the history of the German literature, as it introduced into the country a better taste, and tended greatly to improve the language, which, previously to this, had been much neglected. Rabener had before this been appointed controller of the taxes in the circle of Leipfie, a place of great labour, and which required an exact knowledge of the laws of the country, and the most inflexible integrity. Notwithstanding, however, the attention which the duties of this office required, he found leisure to continue his literary pursuits; and towards the end of 1751, composed his satirical letters, in which he introduces perorations of every kind and character, all of whom speak in the language suited to their condition. In 1753 he was appointed chief secretary to the directors of the taxes at Drefden; and two years afterwards he published the fourth and last volume of his fates, which contains "A Burlesque Explanation of the Proverbs of Sancho Panza," "The Fable of April," and "The Excuse and Reparation." After this he began to write for the stage, and composed a comedy in four acts, entitled "The Freethinker," which, with many other papers and letters, were burnt, together with his house, during the siege of Drefden, in 1760. He now abandoned his literary labours, but his friends obtained from him a collection of letters, which were afterwards published by Welfs. These were never intended for the public, but they are written with so much truth and sincerity, and exhibit a more correct picture of the author than any pen could have drawn. His health began to decline soon after his loss in 1760, and in 1767 he experienced a paralytic stroke, which was repeated in 1769; but he lingered out till March 1771, when he died. "He was," says his biographer, "among the small number of those privileged men, whom nature has endowed with every quality necessary to their state. He thought and spoke in a manner peculiar to himself: his pleasantry flowed as from an abundant source; he never sought for them, and they appeared so natural, pleasant, and lively, that it was impossible not to be struck by them. But he displayed his wit only among his friends; he never lavished it on the rich and great; on the contrary, he concealed it, when invited merely for the purpose of being heard. He always spoke the truth, without regard to person or rank." Rabener, says he, was the favourite author of Germany, who wrote poetically in prose, whose satirical, sportive genius possessed fault without gall. Rabener's works are generally known throughout Europe, having been translated into the French, English, Dutch, and Swedish languages. Gen. Biog.

RABENSPURG, in Geography, a town of Auffria; 8 miles N.E. of Lifferdorff.

RABENSTAIN, a town of Auffria, on the river Bie-
lach; 8 miles S. of St. Polten.

RABENSTEIN, a town of Bohemia, in the circle of Leitmeritz; 40 miles E. of Prague. N. lat. 50°. E. long. 17° 15'.—Allo, a town of the duchy of Stiria; 11 miles N.N.W. of Gratz.—All, a town of Bavaria, in the bishopric of Bamberg; 2 miles S. of Weifenfeld.

RABIA Paron, in Chronology, is the name of the third month of the Arabic year, consisting of thirty days; and Rabba posterior is the name of the fourth month, consisting of twenty-nine days.

RABICH, a name given by Leo Africanus to a tree or shrub growing very plentifully in many parts of Africa, the fruit of which is much esteemed by the natives. He says that the tree rabich is prickly, and that the fruit is round, and like a cherry, but smaller, and of the taste of the jujube.

RABIEL, a name given by some authors to dragon's blood.

RABIES, in Medicine, that peculiar state of the nervous system, which is produced by the bite of a rabid animal, and which is commonly, but improperly, called madness. As the dog is the principal source of this disease, the word rabies is commonly united with the epithet canina. See HYDROPHOBIA.

RABINAL, in Geography, a town of Mexico, in the province of Vera Paz; 40 miles S.S.W. of Vera Paz.

RABINET, a name formerly given to a small piece of ordnance, between a falconet and a bafe. Its dimensions, &c., see under CANNON.

RABIRA, a word used by some of the chemical writers to express tin.

RABISHI, in Geography, a river of the island of St. Vincent, forming a bay on the eastern coast, near the southern extremity, where it runs into the sea. N. lat. 13° 5'. W. long. 61° 11'.

RABLAY, a town of France, in the department of the Mayne and Lore; 9 miles N. of Villiers.

RABLES, Ile, aux, a cluster of small islands at the entrance of lake Superior, in Upper Canada, and at the east end of it, eait of White-Fish island, and pretty close to the main land.

RABNABAD, a town of Hindooftan, in Bengal, at the mouth of the Ganges; 90 miles S.S.E. of Mahmu-
pour.—Allo, a small island on the coast of Bengal, at the mouth of the Ganges. N. lat. 22°. E. long. 90° 30'.—Allo, one of the mouths of the Ganges, which opens into the bay of Bengal. N. lat. 22°. E. long. 90° 20'.

RABNITZ, a river of Hungary, which runs into the Donaue, a little below Raab.

RABOGH, a town of Arabia, in the province of Yemen, near the coast of the Red sea, where the Arabs live in huts; 105 miles S.W. of Medina.

RABOLANE, in Ornithology, a name given by many to the lapopons, a bird found on the flowy mountains, and called by some the white partridge.
RABY, in Geography, a small township of America, in New Hampshire, in Hillsborough county; about 65 miles W. by S. of Portsmouth; incorporated in 1750. Its name has been since changed.—Also, a town of Bohemia, in the circle of Prachatitz, containing a citadel, at the siege of which, Zifca, general of the Hussites, lost his only remaining eye; 4 miles S. of Horadálovitz.—Also, a town of Sweden, in Sudermanland; 7 miles N. of Nyköping.

RACA, or RACHA, a Syriac term, found in the Gospel of St. Matthew, chap. v. 22, and preferred in most translations.

Father Simon observes, that the Greek translator of St. Matthew's Gospel retained the Syriac race, which he found in the original, because it was very common among the Jews. And St. Jerom, Luther, the English translators, those of Geneva, Louvain, Port-royal, &c. still prefer it in their respective languages.

F. Bonhows chooseth rather to express the sense of it in a sort of paraphrase, thus: he that fays to his brother, homme de peu de fains, man of little understanding, shall beare to be condemned by the tribunal of the council, &c.

Most translators, except the English, and F. Simon, for racha write raca; but the former orthography seems the bell founded; all the Latin copies have racing, and all the Greek ones ἱσας, or, with Hefychius, ἱσας, which is the same; all, we mean, but St. Ireneaus, and Beza's copy, now at Cambridge, which have ἱσας. In effect, the origin of the word knews it should be racing; as coming from the Syriac נ(price), raca, of the Hebrew reק, ינ, empty, blank.

RACAISBONE, in Geography, a town of Hindoostan, in Aurungabad; 30 miles S. of Aurungabad.

RACAM, a town of New Mexico, in the province of Hiaqui; 60 miles S.W. of Riochico.

RACAN, Honorat de Bueil, Marquis of, in Biography, a French poet, was born in 1569, of a noble family, in Touraine. When very young, he had a place in the king's bed-chamber, under the duke of Bellegarde. From Malherbe, who was at that time domiciled with the duke, he acquired a fondness for poetry, and obtained instructions in the art of verifying. He at first bore arms, as a profession; but after a time he devoted himself to a life of letters. He was one of the earliest members of the French academy, and though almost wholly without the advantages of education, he obtained reputation as a writer. His most popular work was entitled "Bergeries." He composed in various styles, and wrote translations of Pfalms, and many sacred odes taken from the Pfalms, and other scriptural poems. In prose he published "The Life of Malherbe;" "A Difcorfe pronounced before the Academy;" and some "Letters." He died in 1679, at the age of 81. Of his works a new edition was given at Paris, in 1724, in 2 vols. 12mo.

RACCA, RACAH, Rika, or Racca-Rica, in Geography, a town of the Persian empire, in the province of Dizarbekir, and pashalic of Orlu, the capital of the district named Dvor Modjar. It is situated on the eastern bank of the River Euphrates, at the mouth of a small river named Beles, (the ancient Billicha,) and was founded, according to Phiny, by Alexander the Great. It was first called Nicophorium, and afterwards Callinicum and Leontopolis, from Seleucus Callinicus and the Greek emperor Leo. It was the favourite residence of Haroun al Rashaed, the ruins
runs of whole palace, it is said, are still visible. The position of Racca, in the parallel of 36° N., was ascertained by the celebrated oriental astronomer Mahomed Ben Jaber, surnamed Al-Batani, who passed many years of his life at this place. The town and adjoining country are inhabited by different tribes of wandering Arabs. N. lat. 36° 1'.

E. long. 48° 50'.

RACCA, a river on the north coast of Sumatra, which runs into the sea, N. lat. 2° 30'. E. long. 100° 15'.

RACCANNO, a river of Naples, which runs into the gulf of Tarento, N. lat. 39° 43'. E. long. 16° 42'.

RACCOON, in Zoology. See Raccoon.

Raccoon, in Geography, an island in the Atlantic, near the coast of South Carolina, nine miles long and one wide. N. lat. 33° 3'. W. long. 79° 22'.

Raccoon Creek, a river of Pennsylvania, which runs into the Ohio, N. lat. 40° 58'. W. long. 80° 25'.

Raccoon Island, a small island in Ohio, found, belonging to the state of Georgia. N. lat. 31° 47'. W. long. 81° 12'.

Raccoon Key, a small island or rock in the gulf of Mexico, near the south coast of West Florida. N. lat. 29° 45'. W. long. 89° 21'.

Raccoon Key, a cluster of small islands near the coast of South Carolina. N. lat. 24° 8'. W. long. 79° 15'.

RACCOURY, in Heraldry, signifies the horse as couple, that is, cut off, or shortened; and denotes a cross, or other ordinary, when it does not extend to the edges of the escutcheon, as they always do when absolutely named, without such distinction.

RACE, in general, signifies running with others, in order to obtain a prize, either on foot, or by riding on horseback, in chariots, &c.

Racing was one of the exercises among the ancient Greek games, which was performed in a course, containing one hundred and twenty-five paces; and those who contended in these foot-races were frequently clothed in armour. For a particular account of these races, see STADIUM.

There were properly but two kinds of horse-races at Olympia, namely, the chariot-race; introduced into those games in the 23rd Olympiad (for an account of which see CHARIOT), and the race of riding-horses, which was not admitted till the 33d. Although chariots were in use before riding-horses, as we may conclude from the testimony of Homer, among all whole heroes, Greek and Trojan, no one makes his appearance on horseback, except Diomedes and Ulysses mounted upon the horses of Rhesus (Il. x.), it is nevertheless plain, from this instance, that neither the heroes nor the horses were utter strangers to the art of riding; and it is also evident, from another passage in the 15th Iliad, that horsemanship was carried even to some degree of perfection, at least in the time of that poet, who lived but in the next generation after the siege of Troy, according to the late Isaac Newton. This passage, extracted from Pope's Homer (Il. xv. v. 832.) is as follows:

"So when a horsemans from the wat'ry mead
  (Skill'd in the manage of the bounding steed)
  Drives four fair courlers, practis'd to obey,
  To some great city, thro' the public way:
  Safe in his art, as hide by hide they run,
  He shifts his seat, and vaults from one to one:
  And now to this, and now to that he flies:
  Admiring numbers follow with their eyes."

Some authors (see Rollin's Anc. Hist. tom. v. p. 72. et Amft.) have introduced an exercise like this into the Olympic games, though Mr. Weft professes himself dissatisfied with the authority upon which they depend; and says that in the books which he has consulted, he can find no mention of any other race of riding-horses, besides those of the Celts and the Calpis. As to that particular branch of horsemanship, above described, Eustathius, in his commentary upon Homer, tells us, that in the old schola it is written, that Demetrius says he had seen a man, vaulting in the manner described by the poet, from the back of one horse to another, holding the bridles at the same time, and keeping the horses to their speed, without any interruption or incumbrance. This assertion implies that such a feat was very uncommon, and consequently that no such exercise could ever have been admitted into any of the games of Greece. The word ἑξαδίκη, used by the poet in the beginning of this simile, says Mr. Weft, may possibly have induced some people to imagine, that the riders of the horses called ἑξαδίκη, eiders, were accustomed to leap from one horse to another, as if that word was a term of the manage, of which the verses that follow were merely an explanation. It is certain, however, from a passage in the Odyssey (E. v. 371.) that by ἑξαδίκη, Homer meant to signify no more than a riding-horse, and consequently that by the word ἑξαδίκη, which is derived from ἑξά, no more is to be understood in this place than simply to ride. This interpretation of ἑξαδίκη, edit', may be further confirmed by the authorities of Pindar and Pausanias, and particularly by a story related by the last mentioned author (lib. vi. c. 13.) of a mare, named Aura, belonging to one Phidolas, a Corinthian. This mare, says the historian, having accidentally thrown her rider into the air he fluried from the barrier, continued the race of her own accord, and turned round the pillar as if the rider had been still upon her back; upon hearing the trumpet, she mended her pace, till coming in before her antagonists, she stopped short over-against the judges of the games, as conscious of having gained the victory. The victory was accordingly adjudged to her master Phidolas, who, by erecting a return a statue to her honour, intended to whom the merit of that victory was due. In this story, there is no mention of any other horse or mare, that shared the victory with Aura, and consequently that, in the race called Celis, each competitor made use of but one single horse. Moreover, the victorious Aura was of the feminine gender, and hence we may infer, that in all the races, as well of riding horses as of chariots, mares or horses were indiscriminately used; excepting in the race named Calpis, in which mares only were employed. And further it appears, that though the rider was thrown off in the very beginning of the race, yet the crown was awarded to Phidolas, the master of Aura; to whom certainly no less was due, than if his mare had conquered under the conduct and dexterity of her rider. It appears also, by the circumstance of Aura's mending her pace upon hearing the trumpet, that the trumpet either did not sound during the whole race, but at the last round only, or that it sounded differently in different periods of the course. There was, however, a meaning in the found of the trumpet, which Aura, probably an old fable, understood.

The race of full-aged riding-horses was instituted in the 33d Olympiad, and that of the ἑξαδίκη, or under-aged riding-horses, in the 131st. It is a well-known fact that chariots were used in war above 1000 years before cavalry was introduced among the ancients. They seem to have had a terrible notion of being mounted upon the back of a horse, and have accordingly made monitors of those whom they first beheld in that attitude, to which they were not very speedily reconciled. Their amazement gradually diminished; and their intercourse with other nations not only rendered
rendered riding-horses familiar to them, but convinced them likewise of the advantages accruing from the use of cavalry. Hence it came to pass, that an order of equites, or horsemen, was instituted in most of their commonwealths; to whom, as in Athens, was allotted the second rank in the state. Upon the same principle, perhaps, the Hellenides, or riding-horse, was admitted into the Olympic hippodrome, and held in such estimation, that although the race of riding-horses was neither so magnificent nor so expensive, and consequently not so royal, as the chariot-race, yet we find, among the competitors in this exercise, the names of Philip, king of Macedon, and Hiero, king of Syracuse. To the latter is ascribed the first Olympic ode of Pindar, in which honourable mention is made of the horse Pherecy, whose feet were gained for his master the Olympic crown. The race of the Calpe was performed by mares. (See Calpe.) The length of this race, and also that of the Celes, are not ascertained; but it is reasonable to suppose, that the latter, distinguished, as we have already observed, into two classes, one of full-aged, and the other of under-aged horses, composed of the same number of rounds as those of the chariots, distinguished in like manner into two classes. Mr. Wall has not been able to determine the different ages that ranked the horses in one or the other class; nor whether the weight of the riders, or the sizes of the horses, were taken into consideration. These points seem to have been left to the discretion of the Hellanides, who were appointed to examine the young horses that were entered to run for any of the equestrian crowns (Paul. i. iv. c. 24.), and who were sworn before the statue of Jupiter Horaeus, to give a true and impartial judgment upon the matters left to their examination, without taking any reward; and not to discover the reasons which disposed them to reject some, and admit others. Wall's Dissertation on the Olympic Games. Sec. 14. See Hippodrome.

Race, in Genealogy, a lineage, or extraction, continued from father to son.

The word is French, derived from the Latin radix, root; as intimating the root of the genealogical tree.

In several orders of kindred, as in that of Malta, &c. the candidates must prove a nobility of four races or defeants.

In some republics the magistrates are to prove themselves of plebeian race, to be qualified.

The French reckon their kings by races; as, the first race, the second race, the third race. We also lay the race of the Ottomans, the Aracidae, the Ptolomies, &c.

Race, in Natural History. See CibdeloPlacita.

Race, the mark made on timber, &c. by a tool called a racing-knife.

Race, Cape, in Geography, a cape on the S.E. coast of Newfoundland. N. lat. 46° 40'. W. long. 53° 30'.

Race Point, a cape on the coast of America, W. of Cape Cod. N. lat. 42° 24'. W. long. 76° 12'.

RaceM, in Gardening, the long mode of chaff-flowering and fruiting which takes place in some sorts of plants and fruit-trees, as in the grape-vine, and the different kinds of currants. See Racemus.

RaceMifierous, in Botany, denotes bearing in clusters.

RaceM, in Botany and Vegetable Physiology, a cluster, is a mode of inflorescence, in which several flowers, each supported on its own proper stalk, are connected by one common stalk, either simple or compound. A bunch of Curtains is a simple racemus; the inflorescence of the Woody Nightshade, Solanum Dulcamara, is a compound one. In the American plant called Astra racemosa, the clusters are simple, but aggregate. A racemus differs from a spica, or spike, in having a partial stalk, as above described, to each flower; it is moreover generally understood to be drooping or pendulous, and to have the flowers expand all nearly at one time. On the contrary, a spike is most frequently erect; the flowers open in very gradual succession, insomuch that the lowermost may have partly perfected their seeds, before the uppermost expand; and especially, they are individually fesile, at least at the time of their expansion. To these characters may be added, that a spike is crowded or dense; a cluster lax or scattered. It must be allowed that botanists, even of the first rank, are incorrect in the application of these terms. The male inflorescence of Quercus, the Oak genus, because drooping and loosely disposed, with all the flowers in perfection nearly at the same time, is termed a racemus; though it polleffes the most elegant character of a spica, fesile flowers. On the other hand, Veronica Spicata, having a dense upright series of flowers, expanding gradually, is said to be spik'd, though each separate flower has a partial stalk. A little latitude must necessarily be allowed, though it is very desirable that botanists should be more exact in the use of these and other terms, than they sometimes are. See Spica and Inflorescence.

Racer, in Gardening, a name applied to a fort of fward-cutter, or cutting implement, used in racing out or cutting through the surface of grass fward, and dividing it into proper widths, lengths, and thicknes; for turf intended to be cut up for laying in pleasure-grounds, or other places, and always necessary preparatory to the work of faying or cutting up the turf with the turfing-iron. It is also useful for cutting and straightening the edges of grass verges in such grounds, as well as for many other purposes.

It is a tool which is very simple in its construction, merely consisting of a strong wooden handle, about four feet long, having the cutter fixed at the lower end, in the form of a half moon, with the edge downward, to cut into the fward; the handle should be about an inch and a half thick, growing gradually thicker towards the lower end.

In using the tool, it is pushed forward so as to cut or race out the fward in an expeditious manner. And in cutting turfs with it, it is necessary first to mark out on the fward the width of the turf intended, which should generally be a foot wide, and a yard long, and about an inch or inch and a half deep; then draw a line tight, first lengthways, striking the racer into the fward close to the line, running it along expeditiously, so as to cut its way, and divide the fward to a proper depth, afterwards placing a line a foot farther, and racing it out as before, and so on, to as many widths as may be wanted; and then, with the line placed cross-ways, to race out the fward accordingly in yard lengths. The fward being thus raced out, the turf-cutter with the turfing-iron should proceed to cut them up and lay them off from the ground. This small implement is likewise very convenient for many other little purposes about pleasure grounds and gardens, as tho' of cutting the edges of the verges which are laid with turf, and straightening the edges of the borders in different parts. See Turf.

Racha. See Raca.

Racha, in Geography, a town of Bohemia, in the circle of Leitmeritz; 8 miles E. of Leitmeritz.

Ranchesdorf, a town of Bavaria, in the bishopric of Bamberg; 15 miles N. of Bamberg.

Rachetum, from the Fr. racbeter, redimer, the compensation or redemption of a thief.

Racha,
RACHIA, in Geography, a town of Ithria; 7 miles N.E. of Pedena.

RACHIALGIA, in Medicine; a term given by Atrius, and adopted by the nomenclators, to denote certain colicky pains in the bowels, which were supposed to originate from the nerves of the spine, and especially the colic from the potion of lead, or COLICA PIETONUM; which fee. The word is from πειω, the spine, and αγιος, pain. See Sauvages Nofol. Meth. clvii. gen. 29.

RACHIS, or rather Rhaechis, in Botany, from πειω, the back-bone, is the common stalk, or receptacle, of the florets, in the spikelets of graminies; or of the spikelets themselves in Silium, Tritecum, Secale, Hordeum, Rothbildia, &c. The same term is applied to the rib, or leaf-stalk, of ferns, which is often wound or bordered. The Rhaechis in both these inflexions is frequently jointed; by which in the former, the ripe foods of such graminies, wrapped up in their hulls, are the more readily dispersed. The part in question being in some cases smooth, in others variously hairy or bearded, affords excellent specific distinctions; witness the genus Avena.

RACHISAGRA, a term used by some physicians for the gout in the spine of the back.

RACHITIS, in Medicine, from πειω, the spine, (because the spinal marrow was supposed to be the seat of the disease, a malady corruptly termed in English the Rickets; which fee.

RACHKOKE, in Geography, one of the Kurilkoi or Kurilly islands in the Eastern or Pacific ocean: distant from Muf- fyr, another of the said islands, about 120 versts. Its length is about 20 versts, and its breadth the same, and it presents the appearance of a solitary mountain rising upwards from the sea. It was formerly covered with verdure, with shelves of rocks, where sea-fowl in great number made their nests: but these rocky shelves have been demolished by the eruption of subterraneous fires, which split the summit of the mountain, throwing up vast quantities of stones and ashes; and since that time, the island has always continued burning. At this eruption those places on the shore where formerly they had thirteen fathom water, were filled up with rubbish and ashes into shoals and banks.

RACLING, in Ancient Geography, the Rica, of Pro- lemy, near the N.E. coast of Ireland, memorable as the retreat of Robert I. of Scotland.

RACOL, in Geography, a town of Hindoostan, in Soonda; 16 miles S.S.E. of Goa.

RACOR, a district or province of Hindoostan, in Golcoada, bounded on the N. by the Kithna, on the E. by Canoul, on the W. by the S. by the Mad, and on the W. by Sanaore.—Also, a town of Hindoostan, and capital of the above-mentioned province, on the S. side of the Kithna, and not far above the confluent of the Toomboodra with it, and below that of the Beemah; belonging to the Nizam. It is four days' journey from Adoni, reckoning a day's journey at 22 British miles in road distance, and 17 or 18 geographical miles; 91 miles S.W. of Hyderabad. N. lat. 16° 24'. E. long. 78° 2'.

RACHOSIS, from πειω, lacerus, a disease, in which the feromum is relaxed and excoriated.

RACHOUR, in Geography, a town of Hindoostan, in the cincar of Gurry Mundella; 20 miles S.S.W. of Guerrah.

RACHOURE, a town of Hindoostan, in Mylore; 20 miles S. of Gurramaconda.

RACHOW, a town of Poland; 36 miles S.S.W. of Lublin.

RACINE, John, in Biography, an eminent French poet, was born in 1639. He was educated at the convent of Port-Royal, near Paris; after this he went through a course of philosophy at the college of Harcourt, and then made his appearance before the public in an ode on the king's marriage. This effort was, through the interest of Colbert, rewarded with a present and a small pension. Elated with the success that crowned his first effort, he determined to follow poetry as a profession; and, rejecting the offer of an uncle, a prior, who offered to resign his benefice to him, provided he would enter into holy orders, he fixed his residence at Paris. In 1664 he brought upon the stage his first tragedy, entitled "La Thébaïde ou les Frères ennemis." It was written in the manner of Corneille, which he soon after quitted for one of his own; a judicious change, says Voltaire, since the characteristics of these two masters of the French drama were extremely different. He next published his "Alexandre," which followed by his "Andromaque." About this time he was presented to the priory of Epinay, but not being in orders, he was, after a law-suit, obliged to quit. His "Andromaque," which established his character as a tragedian, was soon followed by the comedy "Les Plaideurs," which, though it obtained for him the praise of Molière, and was well received at court, was his only attempt in that walk. Between the years 1670 and 1678, he published his "Britannicus," "Berenice," "Bajazet," "Mithridate," "Ephigene," and "Pandare." His popularity and well-earned reputation excited a strong party against him: the chagrin which he underwent from the arts of his enemies, and the over-sensibility to criticism, which led him to confide, in the confidence of friendship, that the work critique made upon his works caused him more uneasiness than the greatest plaudits had given him pleasure, inspired him with the resolution of renouncing poetry and turning Carthusian. He was, however, prevailed upon to change his plan, and to marry; he accordingly formed an alliance with the daughter of a gentleman in the treasury of Amiens, by whom he had several children. At the same time he ceased to write for the stage, and thereby reconciled himself with his old friends of the Port-Royal. Racine now became a courtier, and obtained the situation of gentleman in ordinary to the king, to whom he made himself very useful. He was also appointed to the office of histrionographer-royal, in conjunction with his friend Boileau, which they made a complete success. He was prevailed upon by Madame Manteenon to write a dramatic piece on a scriptural subject, for the ladies of her foundation of St. Cyr, and his "Esther" was performed by them in 1689, with great applause, in the presence of the whole court. He followed it with "Athalie," acted by the fame ladies in 1691. Madame Manteenon, deeply affected with the mysteries of the people in the latter years of Lewis's reign, engaged Racine to draw up a memoir on the subject. This he did in a fine manner, as to give great offence to the king, who happened to obtain a sight of it from a lady to whom it had been lent. Racine was excluded from the court, a circumstance that brought upon his mind, that he fell into a state of melancholy, of which he died in 1699, at the age of 69. For a character of this writer we shall be indebted chiefly to the General Biography. He was polite in his manners, with the affected costumes of a courtier, which was, however, a mark of his actual disposition, for, in reality, he had much gall and spleen in his character. In religion, however, corrected, in a good measure, these defects, and in all the relations of domestic life he was exemplary. As a dramatic writer he is supposed to have ranked with Corneille, though in many points he even surpassed him. His characteristical are tender,
RACIN, Louis, son of the preceding, also a distinguished poet, was born at Paris in 1692. He was, however, not more distinguished for his poetry than for his piety, and adopted the ecclesiastical habit. In a flight of retirement, in 1720, he published his poem "On Grace." The chancellor d'Angoulême, during his own exile at Frenses, brought Racine again into the world, and cardinal Fleury afterwards gave him a place in the finances. He married, and lived very happily in his family, till the loss of an only son threw him into a deep melancholy. His religious sentiments took full possession of his soul, the fervour of which may be estimated by the line from Tibullus which he inscribed on the crucifix which ever accompanied him:

"Te speecon suprema mili cum veneris hora,  
Te teneam moriens deficiente manu."

He died in 1763, at the age of 71. His poetical writings are "Poems on Religion and Grace;" "Odes," of which the diction is splendid, and the sentiments elevated; "Epitaphs," and a "Translation of Milton's Paradise Lost." In prose he wrote "Reflections sur la Poësie;" "Memoires sur la Vie de Jean Racine;" "Remarques sur les Tragedies de J. Racine;" besides these he contributed several dissertations to the Memoirs of the Academy of Inscriptions, of which he was a member. His works were collected and published in 6 vols. 12mo.

RACINE, Bonaventure, a learned French priest and ecclesiastical historian, was born at Chauny, in the diocese of Noyon, in the year 1708. He received an excellent education at the Mazarin college at Paris, where he not only studied the ancient languages, but entered pretty fully into the different branches of philosophy, divinity, and the studies connected with ecclesiastical history. At the age of twenty-one he was entrusted by the archbishop of Alby, as a fit person, to re-establish the college of Rabalens, a town in his diocese. To this design he devoted his talents with unwearying zeal and fidelity, and was abundantly compensated by the success which attended his labours. This institution was, in a short time, crowded with students, who admired from his lectures a taste for science and literature. Thus usefully employed, he became an object of the jealousy of the witty Jesuits, who calumniated him to be banished from Rabalens. He retired to Montpellier, where M. Colbert engaged him to undertake the direction of the college of Janel; from this place he was also driven by the same persecutors, and he found it necessary to withdraw secretly to Paris, where he was invited to undertake the education of certain young persons at the college of Harcourt, in connection with some other ecclesiastics. Here his old enemies the Jesuits pursued him, and an order was obtained from cardinal Fleury, in 1734, to deprive him of his office of tutor. In the following year M. de Caylus, bishop of Aixerre, nominated him to a canonry in his cathedral, and ordained him priest; but his new dignity produced no alteration in his manner of living, nor in the distribution of his time, which was almost wholly spent in devotion and study. From this time he set about preparing to publish the collections that he had made in ecclesiastical history, and in 1748 he went into the world the first volumes of an "Abridgment of Universal History," containing the principal Events in every Century, with Reflections," in 12mo. These were followed by others, to the number of thirteen, the last making its appearance in the year 1754. This work, written in a neat, perspicuous, and simple style, was well received, and became extremely popular. The labour which it cost him his weak constitution was unable to sustain; he sunk under its exertions in the 47th year of his age. He was characterized by the excellence of his manners and the amiable benevolence of his temper, and he had an ardent zeal for what he regarded as truth, which approached to enthusiasm. Two other volumes had been added since his death to the Histories; but they are the work of an inferior hand, and unworthy of being placed in conjunction with those of Racine. Moretti.

RACING, the riding of heats for a plate or other premium. Horses for this use should be as light as possible, large, long, and well-shaped, nervous, of great mettle, and good wind, with small legs, and neat small-shaped feet.

The first thing to be considered in this sort of gaming is the choice of a rider; for it is not only necessary that he should be very expert and able, but he must also be very honest.

He must have a very close seat, his knees being turned close to the faddle skirts, and held firmly there, and the toes turned inwards, so that the spurs may be turned outward to the horse's belly; his left hand governing the horse's mouth, and his right the whip. During the whole time of the race, he must take care to sit firm in the saddle, without wavering or standing up in the stirrups. Some jockeys fancy this is a becoming feat, but it is certain, that all motions of this kind do really incommodate the horse. In spurring the horse, it is not to be done by flinging the calves of the legs close to the horse's sides, as it was intended to press the wind out of his body; but, on the contrary, the toes are to be turned a little outwards, that the heels being brought in, the spurs may just be brought to touch the sides. A sharp touch of this kind will be of more service toward the quickening of a horse's pace, and will sooner draw blood than one of the common coarse kicks. The expert jockey will never spur his horse until there is great occasion, and then he will avoid striking him under the fore-knobs between the shoulders and the girth; this is the tenderest part of a horse, and a touch there is to be reserved for the greatest extremity.

As to whipping the horse, it ought always to be done over the shoulder, on the near side, except in very hard running, and on the point of victory; then the horse is to be struck on the flank with a strong jerk; for the kick is the most tender of all there, and most sensible of the lash.

When a horse is whipped and spurred, and is at the top of his speed; if he claps his ears in his pole, or whisks his tail, it is a proof that the jockey beats him hard, and then he ought to give him as much comfort as he can, by faw-
Racing.

ing the snaffle backwards and forwards in his mouth, and by that means forcing him to open his mouth, which will give him wind, and be of great service. If there be any high wind flitting in the time of riding, the artful jockey will let his adversary lead, holding hard behind him, till he sees an opportunity of giving a loose; yet in this case, he must keep a close behind, that the other horse may keep the wind from him; and that he, sitting low, may at once shelter himself under him, and affix the strength of the horse. If the wind happen to be in their back, a just contrary method is to be taken with it; the expert jockey is to keep directly behind the adversary that he may have all the advantage of the wind to blow his horse along, as it were, and at the same time intercept it in regard to his adversary.

When running on level carpet-ground, the jockey is to bear his horse as much as the adversary will give him leave, because the horse is naturally more inclined to spread himself on this ground: on the contrary, on deep earths he may have more liberty, as he will then spare himself.

In riding up hill the horse is always to be favoured, by bearing him hard, for fear of running him out of wind; but in running down hill, if the horse's feet and shoulders will bear it, and the rider dares venture his neck, he may have a full loose. If the horse have the heels of the reft, the jockey must always spare him a little, that he may have a reserve of strength, to make a pull at the last pull.

A great deal depends on the jockey's knowing the nature of the horse that is to run against him; for by managing accordingly, great advantages are to be obtained: thus, if the opposite horse is of a hot and fiery disposition, the jockey is either to run just behind him, or check by jouл with him, making a noise with the whip, and by that means forcing him on faster than his rider would have him, and consequently spending him so much the sooner; or else keep just before him, in such a flow gallop, that he may either over-reach, or by treading on the heels of the fore horse, endanger tumbling over.

Whatever be the ground that the adversary's horse runs worst on, the cunning jockey is to ride the most violently over; that by this means it will often happen, that in following he either flumbles or claps on the back fins. The several corrections of the hand, the whip, and the spur, are also to be observed in the adversary, and in what manner he makes use of them: and when it is perceived, by any of the symptoms, of holding down the ears, or whiffing the tail, or stretching out the nose like a pig, that the horse is almost blown, the jockeys is to keep him on to this speed, and he will be soon thrown out, or dillanced. If the horse of the opponent looks dull, it is a sign his strength fails him; and if his flanks beat much, it is a sign that his wind begins to fail him, and his strength will soon do too.

After every heat for a plate, there must be dry straw, and dry cloths, both linen and woollen, ready to rub him down all over, after taking off the sweat with what is called a sweat-knife; that is, a piece of an old sword-blade, or some such thing. Some advise the steeping of the cloths in urine and saltpetre the day before, and letting them be dried in the sun for this occasion. After the horse has been well rubbed with these, he should be chafed all over, with cloths wetted in common water, till the time of starting again. When it is certainly known that the horse is good at the bottom, and will flick at the mark, he should be rid every heat to the belt of his performance; and the jockey is, as much as possible, to avoid riding at any particular horse, or flaying for any, but to ride out the whole heat with the best speed he can. It, on the contrary, he has a fiery horse to ride, and one that is hard to manage, hard-mouthed, and difficult to be held, he is to be started behind the rest of the horses, putting all imaginably coolness and gentleness; and when he begins to ride, if some command, then the jockey is to pull up to the other horses; and if they ride at their pace, and are hard held, they are to be drawn on faster; and if it be perceived that their wind begins to rake hot, and they want a top, the jockeys is to keep them up to that speed; and when they are all come within three quarters of a mile of the poll, then is the time to pull for it, and use the utmost speed in the creature's power.

When the race is over, the horse is immediately to be clothed up, and rode home; and immediately on his coming into the stable, the following drink is to be given him. Beat up the yolks of three eggs, and put them into a pint and a half of new milk made warm; let there be added to this three pennyworth of saffron, and three spoonfuls of salted-oil, and let the whole be well given with a horn. After this he is to be rubbed well down, and the saddle-place rubbed over with warm tallow, and the places where the spurs have touched, with a mixture of urine and salt, and afterwards with a mixture of powder of jet and Venice turpentine; after this he should have a feed of yce-bread, then a good mahl, and at some time after these, as much hay and oats as he will eat. His legs, after this, should be bathed some time with a mixture of urine and saltpetre.

For the preparation of the horse before running, &c. see Plate.

We shall here observe, that horse-races were a species of amusement known in England in very early times. Fitz-Stephen, who wrote in the days of Henry II. records the great delight which the citizens of London took in the diversion. "Races appear likewise to have been in vogue in the reign of queen Elizabeth, and have been carried to such excess as to have injured the fortunes of the nobility." Lord Herbert of Cherbury (see his Life by Mr. Walpole, p. 51) enumerates these among the sports which he thought unworthy of a man of honour. "The exercize," says he, "I do not approve of in running of horses, there being much cheating in that kind; neither do I see why a brave man should delight in a creature whose chief use is to help him to run away." Jarvis Markham, who wrote on the management of horses in 1599, mentions running horses; but at this time there were only private matches made between gentlemen, who were their own jockies, and rode their own horses. However, in the following reign of James I., public races were established; and Garterly, in Yorkshire, Croydon, near London, and sometimes Theobald's, near Ewrehall-chaise, where the king resided, were the courses in which they were performed. The horses at this time were prepared for running by the discipline of food, physic, airing, and sweat and clothing, which composed the present system. The weight also which each horse was to carry was rigidly adjusted; the usual weight of the riders being flanked at ten founces, who were put into scales, and weighed before they started. Most of the celebrated races in the kingdom were called bell-courses, the prize and reward of the conquering horses being a bell. To this purpose, Camden says, that in 1607 there were races near York, and the prize was a little golden bell. Upon this Be严重er offers a conjecture, whether the phrase of "bearing the belt," which implies being comparatively the belt or most excellent, and corresponds with the expression of bearing the palm among the ancients, as a reward decreed to the swiftest horse in a race, is not more aptly deduced from this custom,
culm, than from the method of tying a bell round the neck of the sheep, which leads the flock, and is, therefore, counted the bell. 

About the latter end of the reign of Charles I. it was customary to have races performed in Hyde Park. See the Comedy of the Merry Beggars, or Jovial Crew, written in 1644, in Dodgley's Collection of Old Plays. 

Racing was much encouraged by Charles II. after his restoration: he gave public rewards and prizes, and appointed races for his own amusement at Datchet Meadow, where he rode at Windsor. But the most distinguished spot for these exercices was Newmarket, which was at first frequented for the purpose of hunting, and seems not to have been destined to be a horse-course till some time before the troubles of the reign of Charles I., when races were discontinued; but they were revived soon after the Restoration. The king attended in person, and established a house for his accommodation, and kept and entered horses in his own name. Instead of bells, a silver bowl or cup, of the value of a hundred guineas, was allotted for a prize; and upon this royal gift the exploits of the successful horse, and his pedigree, were generally engraved. The sum of a hundred guineas is now given in lieu of the silver bowl. 

When William III. was advanced to the throne, he not only added to the plates given to different places in the kingdom, but founded an academy for riding. Queen Anne continued the bounty of her predeccessors, with the addition of several plates. George I., towards the end of his reign, discontinued the plates, and gave the sum of a hundred guineas in their room. 

In the thirteenth year of George II. an act was passed for the suppression of races by pones, and other small and weak horses, by which all matches for any prize under the value of 50l. are prohibited, under a penalty of 200l. to be paid by the owner of each horse running, and 100l. by such as advertise the plate; and by which each horse entered to run, if five years old, is obliged to carry ten stone; if six, eleven; and if seven, twelve. It is also ordained, that no person shall run any horse at a course, unless it be his own, nor enter more than one horse for the same plate, upon pain of forfeiting the horses; and also every horse-race must be begun and ended in the same day. Horses may run for the value of 50l. with any weight, and at any place. 13 Geo. II. cap. 19, 18 Geo. II. cap. 34. Pennant's Brit. Zool. vol. i. p. 6, &c. Breenger's Hist. and Art of Horfemanship, vol. i. p. 185, &c.

We shall here add, that at Newmarket there are two courses, the long and the round: the firt is exactly four miles, and about three hundred and eighty yards, i.e., seven thousand four hundred and twenty yards. The second is fix thousand six hundred and forty yards. Children, the swiftest horse ever known, has run the first course in seven minutes and a half, and the second in fix minutes forty seconds; which is at the rate of more than forty-nine feet in a second. But all other horses take up at least seven minutes and fifty seconds in completing the first and longest course, and seven minutes only in the shortest, which is at the rate of more than forty-seven feet in a second, and it is commonly supposed that these couriers cover, at every bound, a space of ground in length about twenty-four English feet. 

RACITZA, in Geography, a town of Bukovina; 7 miles N. of Czernaucz. 

RACK, a small island near the coast of Virginia. N. lat. 37° 19'. W. long. 75° 51'. 

RACK, Lower and Upper, two small islands near the coast of Virginia; the former in N. lat. 35° 20'. W. long. 75° 50', and the latter in N. lat. 37° 20'. W. long. 75° 43'.

RACK, an engine of torture furnished with cords, &c. for extorting confession from criminals. 

The duke of Exeter, contable of the Tower under Henry VI., with the duke of Suffolk, and others, having a design to introduce the civil law into England; for a beginning, the rack, or trake, allowed in many cafes by the civil law, was first brought to the Tower, where it is still preferred; in those days the rack was called the duke of Exeter's daughter. 3 Blunt. 35.

It was occasionally used as an engine of state, not of law, more than once in the reign of queen Elizabeth. (Barr. 92, 466.) But when, upon the affallination of Villiers, duke of Buckingham, by Felton, it was proposed in the privy council to put the affallin to the rack, in order to discover his accomplices; the judges being consulted, declared unanimously, to their own honour, and the honour of the English law, that no such proceeding was allowable by the laws of England. The uncertainty of this punishment, as a test and criterion of truth, was long ago very elegantly pointed out by Tully (pro Sulla, 25.); though he lived in a state in which it was usual to torture slaves, in order to furnish evidence. "Tamen," says he, "illa tormenta gabanert dolor, moderatur natura cinaque tum animi tum corporis, regit quaestor, flecit libido, corrupit tipes, infirmat metus; ut in tot rerum angustiis nihil veratit loci rehaquatur."

The marquis Becerra (ch. 16.), in an exquisite piece of raillery, has proposed this problem, with a gravity and precision that are truly mathematical: "the force of the muscles, and the sensibility of the nerves of an innocent person being given, it is required to find the degree of pain necessary to make him confess himself guilty of a given crime."

RACK, in the Mange, a pace in which a horse neither trots nor amble, but flutters, as it were, between both.

The racking pace is much the same as the amble (which see); only that it is a twifer time, and a shorter tread.

Rack is also a wooden frame, made to hold hay or fodder for cattle. There has lately been much improvement made in the forming of all sorts of racks, both for the flable, cattle-sheds, and field. See CATTLE-feeding, STABLE, and SHEEPLOUISE.

Rack, in Rigging, a short thin plank, with holes made through it, containing a number of belying-pins, used instead of cleats; it is fixed to the shrouds, and nailed over the bowspirt or windlaf.---Alfo, a long shell, containing a number of staves, formerly fixed over the bowspirt to lead in the running rigging. At prefent, wooden faddles, with holes in them, are nailed on the bowspirt for this purpose, being more out of the way, and left liable to be out of order, See SHOT-RACK, and SHROUD-RACK.

To RACK Wines, &c. is to draw them from off their lees, after their having founf long enough to clear and fettle. Hence, Rack-Vintage, is frequently used for the fecind voyage our wine-merchants used to make into France for racked wines; whence they used to return about the end of December.

Rack-Holders, fuch tenants as hold their lands under fuch leafe.

Rack-Loafes, are fuch ferts of leafe as are granted for one or more lives, at the full rack rents, as in Cornwall, and fome other counties. See LEASES OF LAND.

Rack-Rent, is the full yearly value of land let by leafe, payable by tenant for life or years, &c. See RENT.
RACK. Sheep, a sort of long narrow crib, fixed upon wheels, for containing hay for sheep, having a lid or covering on the top. It is very useful in bad weather, in the winter season, as preventing the hay from being Waist, and admitting the sheep to feed conveniently.

RACKAMA, in Geography, a lake of Syria, south of Hella and the ancient Babylon, is about 30 miles long, and flows into the Euphrates.

RACKEBY, a town of Sweden, in Well Gotland; 40 miles N.E. of Uddevalla.

RACKET, a kind of bat for striking the ball at tennis; consisting usually of a lattice, or net-work, of cat-gut, strained very tight over a circle of wood, with a handle or shaft of a moderate length.

The word is formed from the French raquette, which Menage derives from the Latin retettt, a diminutive of retes, net; whence also reticulum, and reticulum.

Pasquier observes, that anciently they used no rackets at tennis, but played with the palm of the hand; and hence he conjectures it is the French call tennis play, jeu de panne. He adds, that rackets were not introduced till a little before his time.

Racket is also a machine which the savages of Canada bind to their feet, to enable them to walk more commodiously over the snow; made much in the manner of a tennis-racket.

Its figure is a lozenge, of which the two obtuse angles are rounded off. It is bound about with very fine thongs of leather, and the meshes of it are much smaller and closer than those of our rackets.

In the middle is fitted a kind of shoe, lined with wool, or hair; to be tied on to the ankle: by which means the feet are prevented from sinking in the snow. Rackets oblige the performer to take very long steps, and, as we say, to walk a great pace, to keep them from knocking against each other.

Racket, in Geography, a river of New York, which runs into the St. Lawrence, N. lat. 45° 13'. W. long. 74° 42'.

RACKIBURN, the name of a small island on the N.W. coast of Ireland, situated near Tellien head, in the county of Donegal. N. lat. 54° 39'. W. long. 8° 44'.

RACING, in Sea Language, denotes the softening of two opposite parts of a tackle together, so as that any weighty body humped by it shall not fall down, although the rope, which forms the tackle, should be loosened by accident or neglect. This expedient is chiefly practised when the boats are hung up to the ship's side in the night, in an open road or bay, left the rope of the tackle should be united by the inattention of some of the crew, by which accident the boat might be considerably damaged, and probably lost or dashed to pieces. Falconer.

Racking Fruit Liquor, the operations of fining and drawing it off. See Cider.

RACKLIA, in Geography, a small rocky island in the Grecian Archipelago, inhabited by two or three poor monks, who take care of a few sheep and goats. N. lat. 36° 53'. E. long. 25° 38'.

RACKNITZ, a town of the duchy of Carinthia; 3 miles S. of Saxenburg.

RACKON, or RACCOON, the ursus lotor of Linnæus, in Zoology, the name by which we commonly know an American animal, called coati by the Brazilians. It is something smaller than the beaver, and is of the shape of the beaver in the body, and its legs are as short as in that creature. The face, cheeks, and chin are white; the upper part of the body is covered with hair, long, soft, and thick; black at the ends, whitish in the middle, and ash-coloured at the root. Sometimes from this mixture of colour the back appears plainly grey; and Marcgrave mentions another species, which is of a deep yellow or ochre colour.

The head is very like that of the fox in shape; but that the ears are shorter, rounder, and naked, and it has from the forehead to the nose a dusky line. The eyes are large, and surrounded with two broad patches of black; the nose is black and sharp-pointed; its tail is very bushy, and annulated with black. Its feet are each divided into five slender toes; by the help of which it climbs trees as expertly as a monkey, and uses the fore-feet as hands, to reach up its food to its mouth. It is a very cleanly animal; and if there be water near, it always washes its food, be it what it will, before it eats it. It feeds on vegetables, but is also very fond of eggs, and will even seize birds if it can catch them. It is also very fond of sweet things and strong liquors, and will get exceedingly drunk; at low-water it feeds much on oysters, watching their opening, and with its paw catching out the flesh, and is sometimes caught in the shell. It is very common in the warm and temperate parts of America, in the mountains of Jamaica, and in the isles of Maria in the South sea, and is a creature easily tamed. It is hunted for its skin; the fur, next to that of the beaver, being excellent for making hats. Ray and Pennant.

RACLER, Fr., to scrape, to rasp, or file a hard body. It is said, in derision of a bad performer on the violin, or any other instrument played with a bow, that he scrapes or rasps the firings; because, in fact, he draws a harsh and disagreeable tone from his instrument, which resembles that produced by scraping or filing a hard body. Even good players on the violin sometimes scrape a little in the same parts of their performance. Suppl. to Encycl., 11th edit.

RACLERGUNGE, in Geography, a town of Bengal; 50 miles N.W. of Burdwan.

RACONIGU, a town of France, in the department of the Stura, containing four gates, with as many bauxbours, well peopled. The king of Sardinia had a palace here. The police is conducted by fifteen counsellors, from whom two syndics are chosen every four months, who act as bailiffs or mayors of the town. It has two parishes, and several religious houses. The inhabitants are industrious, and much employed in making gauzes and flax fluffs; 6 miles N. of Savighano.

RACOPILUM, in Botany, from παπτος, a rent in a garment, or a wrinkle, and παπτος, a hat or cap, the name of one of Palliott de Beauvois's genera of mollusks, whose veil is torn at the side. It ought to be written Rhaporum.

RACOUEBA, a name of Aublet's, of which we find no explanation. See Homalium.

RACOW, Catechism of, in Ecclesiastical History, a system of theology compiled by the most eminent Socinian doctors, and first published at Racow, or Rakow, in Poland, in the year 1609, with a dedication to our king James I. This catechism, or a translation of it, was committed to the flames in England, in the year 1653, by order of parliament. A new edition of it, corrected and enlarged, was published at Stauropolis, in 1684. The Socinians consider this catechism as the great standard of Socinianism, and an accurate summary of the doctrine of that sect. However, Mosheim observes, that it is, in reality, no more than a collection of the popular tenets of the Socinians, and by no means a just representation of the secret opinions and sentiments of their doctors. Hence he says it never obtained among them the authority of a public confession or rule of faith; and hence the doctors of that sect were authorized to correct and con-
tradict it, and to substitute another form of doctrine in its place. But to this account it has been related, that it was he who had been inconfident with the liberty, for which they argue in the preface to this catechism, to have limited their religious inquiries to this standard; and by treating it as a rule of faith, they would have violated their express declarations, that they dictated to no one, and assumed no authority. Moth. Eccl. Hist. See RAKOW.

RACSON-COMPON, in Geography, a mountain of Thibet. N. lat. 31° 52'. E. long. 86° 14'.

RADA, a town of Sweden, in Warmland; 33 miles N. of Carlilladt.—Alfo, a town of Sweden, in Warmland; 35 miles S.E. of Carlilladt.—Alfo, a town of Sweden, in Weft Gothland; 5 miles W. of Gothenburg.—Alfo, a river of Welfphalia, which runs into the Ocker, 5 miles N.E. of Goflar.

RADANAGUR, a town of Hindoostan, in Bahar; 32 miles E. of Rangpur.

RADANI, a town of Sweden, in Weft Gothland; 16 miles N. of Uddevalla.

RADAR, a town of Perfia, in the province of Chorasian; 48 miles N. of Mefchid.

RADASALMI, a town of Sweden, in the province of Savolax; 22 miles N.W. of Nyflot.

RADAVITZA, a town of Prufia, in the patinate of Culin; 22 miles E.S.E. of Culin.

RADAUN, a town of Austria; 6 miles W.S.W. of Vienna.

RADAUTZ, or RADENTZ, a town of Bukovina; 22 miles W.S.W. of Saxaza.

RADAWEIR, a town of Hindoostan, in Candeeith; 14 miles S.W. of Burhanpur.

RADBUZA, a river of Bohemia, that rises in the S.W. part of the circle of Pilzen, and runs into the Miza, near the town of Pilzen.

RADCLIFFE, John, in Biography, an eminent and eccentric physician, was born at Wakefield, in Yorkshire, where his father possessed a moderate estate, in the year 1650. He received the rudiments of his classical education at a school in that town; and at the age of 15, was sent to complete his studies at University college, in Oxford. He took his bachelor's degree in arts in 1669, and removed to Lincoln college, where he was elected to a fellowship. Having determined upon the profession of physic, he went through the courses of botany, chemistry, and anatomy, and was distinguished by the rapidity of his attainments in all these pursuits. Nevertheless he did not apply with zeal or industriily to the studies of the closet, and recommended himself rather by his vivacity, acuteness, and wit, than by any extraordinary acquisitions in any department of knowledge. In the prosecution of his medical inquiries, he contented himself with looking into the works of Dr. Willis, who was at that time practising in London with much reputation. He was polemical, indeed, of very few books; insomuch that when Dr. Bathurst, head of Trinity college, asked him once with surprise where his study was? he pointed to a few vials, a skeleton, and a herbal, and said, "Sir, this is Radcliffe's library." He took the degree of master of arts in 1672, and in 1675 he proceeded bachelor of medicine, and immediately began to practise in Oxford. He professed to pay very little regard to the rules which were generally followed, but confined them on many occasions with great freedom and acrimony; a conduct which did not fail to draw upon him the enmity of all the old practitioners. Nevertheless his reputation and his practice rapidly increased; and before he had been two years in the world, he was very generally consulted, even by those of the highest rank. About this time, in consequence of some witticisms, which he had launched with his accustomed freedom against Dr. Marshall, rector of Lincoln college, the latter unkindly opposed his application for a dispensation for taking holy orders, which the statutes required, if he retained his fellowship, and showed other tokens of invectivity; which induced Radcliffe to resign his fellowship, quit the college, and take lodgings in the town. He continued to practise at Oxford, considering alike in wealth and reputation, until 1684, having taken the degree of doctor in 1682; and he then determined to remove to London, and settled himself in Bow-street, Covent Garden.

His success in the metropolis was unusually rapid; and doubtless of his wit and pleasantries, which rendered him a most entertaining companion, contributed fearfully less than his reputed skill in his profession to forward his progress. In less than a year he was in full practice; and in the second year, he was appointed physician to the princes Anne of Denmarn. In 1688, when prince George of Denmark joined the prince of Orange, and the princes retired to Nottingham, in a state of pregnancy, he was pressed by bishop Compton to attend her, in quality of his office; but he excused himself on account of the multiplicity of his patients. After the revolution, he was consulted by king William and the nobility about his court; an honour which he must have owed entirely to his high reputation, for he never showed any inclination to be a courtier. By his rough independence of spirit and freedom of language, indeed, he ultimately lost all favour at court. In 1699, when king William returned from Holland in a state of severe indisposition, he went for Radcliffe, and having him his swollen ankies, while the rest of his body was emaciated, said, "What think you of these?"—"Why truly," replied the physician, "I would not have your majesty's two legs for your three kingdoms." This freedom was never forgiven by the king, and no interceusions could ever recover his favour towards Radcliffe. In 1694, when queen Mary caught the small-pox, and died, Radcliffe was accused, bishop Burnet says, of negligence and unskillfulness. He soon afterwards lost the favour of princes Anne, by neglecting to obey her call from his too great attachment to the bottle, and another physician was appointed in his place. When queen Anne came to the throne, the earl of Godolphin exerted all his endeavours to reinstate him in his former post of chief physician; but the refusal, alleging that Radcliffe would lend her word again, "that her ailments were nothing but the vapours." Nevertheless he is said to have been consulted in all cases of emergency, in a private way. In 1703 Dr. Radcliffe had an alarming and dangerous attack of pleurisy, which he neglected, and incurred in the outlet by drinking a bottle of wine; he had, however, 100 ounces of blood taken from him by Mr. Bernard, the surgeon, and the next day, in spite of all interceusions, was carried to Kensington. His escape was almost miraculous. The queen asked Mr. Bernard how he did? and when he told her that he was unobservable, and would observe no rules, the answered, that then nobody had reason to take any thing ill from him, since it was plain he used other people no worse than he used himself. During this illness he made a will, by which he disposed of the greater part of his property for charitable purposes, appropriating particularly several thousand pounds for the relief of sick criminals set on there. He recovered, however, and continued in full occupation in his profession, increasing in wealth and influence till the end of his days, and waged a perpetual war with his brethren; who, in their turn, represented him as an active, ingenious, adventurous empiric, whom constant practice
R A D C L I F F E.

practice had brought at length to some skill in his profession. His caprice in the performance of his professional duties appears to have been unbounded; and many anecdotes are related of his refusal to attend on persons of distinction, if he happened to be engaged in pleasanter company, or had any personal pique against the individuals, or if he conceived himself in any way affronted. Thus he fell off suddenly for Bath in 1704, while attending the lady of his servitor, Trevor, because that gentleman sent to Oxford for Dr. Breach to consult with him; which he had done as a compliment to Radcliffe, rather than join any of the London physicians with him. When Dr. Harley was flattered by Guiccard, Swift complains, that by the caprice of Radcliffe, who would allow none but his own surgeon to be admitted, "he had not been well looked after;" and adds in another place, "Mr. Harley has had an ill surgeon, by the caprice of that puppy Dr. Radcliffe, which kept him back so long." On the other hand, he attended the lady of Sir John Holt in a bad illness, with unusual diligence, out of pique to the husband, who was not supposed to be of good birth. In the last illness of queen Anne, he was sent for to her country-house at Carlton about noon, by order, as one account affirms, of the privy council; but he returned an answer, that "he had taken physic, and could not come." It has been stated, however, on the other hand, that he was only sent for on this occasion by lady Marlborough, without any order from the queen or the council; which is countenanced by the following circumstances. On the 5th of August, four days after the queen's death, a friend of the doctor's moved in the house of commons, that he might be summoned to attend in his place. (Dr. Radcliffe had been elected a member for Buckingham in 1713,) in order to be enquired for not attending on her majesty. A letter is preferred, said to have been written by the doctor to one of his friends, on this occasion, in which he says, "I know the nature of attending crowned heads in their last moments too well, to be fond of waiting upon them, without being sent for by a proper authority. You have heard of pardons being signed for physicians before a sovereign's demise; however, ill as I was, I would have went to the queen in a horse-litter, had either her majesty, or those in the commission next to her, commanded me to do so." Whatever was the true state of the cafe, it is certain that Dr. Radcliffe became so much the object of popular resentment, that he was apprehensive of being assassinated, as appears from a letter addressed by him to Dr. Mead, which is extant. "Nor shall I be at any time from home," he says, "because I have received several letters, which threaten me with being pulled to pieces, if ever I come to London." He survived the queen but three months, and died at Carlton, on the 10th of November 1714, at the age of 54. It was believed, that the dread which he had of the populace, and the want of company in his retirement, which he did not dare to leave, contributed to accelerate his death. He was carried to Oxford, and buried in St. Mary's church in that city.

It does not appear that Dr. Radcliffe ever attempted to write, and probably he would not have succeeded as an author. He was beloved, indeed, to have been very little conversant with books; which made Dr. Garth humorously say, that "for Radcliffe to institute a library, was as if an enmune should found a seraglio." He was often the subject of the attacks of ridicule from poets and wits, and even was not spared on the stage; having been severely satirized in a piece acted in 1704, soon after a legal dispute with an apothecary, which was attended by the ladies of the court, and in which the passages affronting the doctor were much applauded. Swift, in Martinus Scriblerus, and Steele in the Tatler, levelled their ridicule at the doctor; and the following severe portrait of him was drawn by Dr. Mandeville, in his Essay on Charity Schools. "That a man with such skill in physic, and hardly any learning, shoud by vile arts get into practice, and lay up great wealth, is no mighty wonder; but that he should so deeply work himself into the good opinion of the world as to gain the general esteem of a nation, and establish a reputation beyond all his contemporaries, with no other qualities but a perfect knowledge of mankind, and a capacity of making the most of it, is something extraordinary. If a man arrived to such a height of glory, should be almost distracted with pride, sometimes give his attendance on a servant, or any mean person, for nothing, and at the same time neglect a nobleman that gives exorbitant fees; at other times, refuse to leave his bottle for his business, without any regard to the quality of the persons that sent for him, or the danger they are in:—if he should be furious and morose, affect to be a humourist, treat his patients like dogs, though people of distinction, and value no man but what would defy him, and never call in question the certainty of his oracles:—if he should insult all the world, affront the first nobility, and extend his insolence even to the royal family:—if, to maintain as well as to increase the fame of his sufficiency, he should scorn to consult with his betters on what emergency afover, look down with contempt on the most deserving of his profession, and never confer with any other physician but what will pay homage to his superior genius, creep to his humour, and never approach him but with all the flavish obsequiousness a court flatterer can treat a prince with:—if a man in his life-time shoud discover, on the one hand, such manifest symptoms of superlative pride, and an inatliable greediness after wealth at the same time; and on the other, no regard to religion, or affection to his kindred, no compassion to the poor, and hardly any humanity to his fellow-creatures:—if he gave no proofs that he loved his country, had a public spirit, or was a lover of arts, of books, or of literature:—what must we judge of his motives, the principle he acted from, when after his death we find that he has left a trifle among his relations, who bleed in need of it, and an immense treasure to an university that did not want it."

Whatever may be the motives of the endowers of splendid institutions for the public use, the nation is at all events benefited for ages, by such noble establishments as the library and infirmary which he founded at Oxford, and which bear his name. He also endowed two travelling fellowships, with an annual income of 500l. attached to each. He had previously caufed the beautiful east window, over the altar, in University college, to be put up at his own expense; and likewise given the money, which was paid for the erection of the master's lodge there, making one side of the eastern quadrangle. He was certainly arantious to the extent almost of fpaning, and never could be induced to pay bills without much following and importunity. A piece of waggery would sometimes conquer this disposition. A pavior, after long and fruitless attempts, once caught him just getting out of his chariot, at his own door, in Bloomsbury square, and set upon him. "Why, you rascal," said the doctor, "do you pretend to be paid for such a piece of work? Why, you have spoiled my pavement, and then covered it over with earth to hide your bad work."—"Doctor," said the pavior, "mine is not the only bad work the earth hides."—"You dog you," said the doctor, "are you a wit? You must be poor; come in," and he paid him. He told Dr. Mead, that the great secret by which he might make his fortune was to "use all mankind ill." Dr. Mead, however, adopted the contrary
contrary axiom, and succeeded even beyond his adviser. Notwithstanding that Radcliffe seems to have literally prac-
ticed this principle, in his dealings both with his patients
and his brethren; and notwithstanding the severe accu-
slations of ignorance and empiricism, which were every where
levelled against him; the universal reputation, which he ac-
quired and maintained, seems to function the testimony of
Dr. Mead, that "he was deferentially at the head of his pro-
fection, on account of his great medical penetration and ex-
perience." See Atterbury's Epitaphical Correspondence.

RADDLE, in Geography, a town of Ceylon, on the
east coast; 5 miles N.E. of Trincomi.

RADDINSDORP, a town of the duchy of Holstein;
6 miles E.S.E. of Eutyn.

RADDLE, in Agriculture, a red ochre of iron, which,
according to Dr. Darwin, has been found useful as a ma-
nure in the northern parts of Staffordshire. Its properties
have not, however, been yet chemically examined as they
relate to manure. See REDDE.

RADEBURG, in Geography, a town of Saxony, in
the margin or of Meilin; 10 miles N.E. of Dresden.
N. lat. 51° 8'. E. long. 13° 53'.

RADECHAU, a town of Bohemia, in the circle of
Königratz; 9 miles S.E. of Trautenau.

RADEGATZ, a town of Germany, in the principality
of Anhalt-Dessau; 13 miles S.S.W. of Dessau.

RADEGURRY, a town of Hindustan, in Canara;
24 miles S.S.E. of Mangalore.

RADENTHAL, a town of the duchy of Carinthia;
13 miles E. of Saxenburg.

RADERAN, a town of Bohemia, in the circle of
Kauzim; 3 miles N.E. of Kauzim.

RADERMACHIA, in Botany, a name originally given
to the Breadfruit (see Artocarpus) by Thunberg, in
honour of one of his great patrons, Joachim Cornelius
Matthew Radermacher, a member of the Dutch council,
and President of the Society of Sciences, at Batavia.
The author, in his Nova Genera, p. 27, represents this gentle-
man as a most distinguished Naxena, and encourager of
Natural History. Nevertheless, the above name has, by
common consent, given way to the expressive one of Forster,
Artocarpus, which is precisely synonymous with Bread-
fruit.

RADERSBERG, in Geography, a town of Germany,
in the principality of Cumbach; 7 miles E. of Bayreuth.

RADES, a town of Tunis, on the N.E. coast; 5 miles
S.E. of Tunis.

RADESCH, or Ratschach, a town of Lower
Carnia, on the Save; 10 miles N.W. of Gurkfeld.

RADHA, in Mythology, is the name of the consort of
the Hindoo deity Krishna. As Krishna was an avatar, or
incarnation of Vishnu, so Radha is understood to be similarly
an avatar of Vishnu's consort Lakshmi; thus incarnated
to accompany her lord in this, his most splendid terrestrial
manifestation. Under the articles Krishna and Lakshmi
some notice will be found on the subject of this. Radha is seen
very frequently portrayed and alluded to in the paintings
and writings of India: Krishna is, indeed, seldom seen with
out her. She is represented of perfect beauty, and is warmly
celebrated in the amatory poeties of Hindoostan. In the
elegant work of Jayadeva, entitled Gita Govinda, a pastoral
drama exhibiting the loves of Krishna and Radha, the lovely
nymph is thus described after a quarrel with her frolicking
and fickle lord, in the morning after the night of reconcili-
ation when affection reigned, and ecstacy crowned the recol-
lection of past forrows. "In the morning the arate, dis-
arrayed, and her eyes betrayed a night without slumber,
when the yellow-robed god, who gazed on her with trans-
port, thus, in his heavenly mind, meditated on her charms:
' Though her locks be diffused at random; though the luftre
of her lips be faded; though her garland and zone be fallen
from their enchanting stations; and though she hides their
places with her hands, looking towards me with bashful
silence; yet, even thus disarrayed, she fills me with ecstastic
delight.' But Radha, preparing to array herself before the
company of nymphs could see her confusion, spake thus with
exultation to her obsequious lover.

'Place, O son of Yadu! with fingers colder than sandal
wood, place a circle of musk on this breast, which resem-
RADHIMA, a name of Radha, consort of the Hindu deity Krishna, as sufficiently noticed under those articles.

RADHOST, in Geography, a mountain of Moravia, in the circle of Prerov; 12 miles E. of Meferitch.

RADHUA, a mountain of Arabia; 30 miles W. of Medina.

RADLESUS, in Anatomy, an epithet applied to parts about the radius, and equivalent to radialis; which see.

RADIAL CURVES. See CURVES.

RADIALIS, in Anatomy, a name given to parts in the forearm, situated near the radius. The adjective radial is also employed to denote the edge, surface, or aspect of any part, which is towards the radius; and in this way, with the term ulnar, affords the means of describing the organs much more accurately and intelligibly, than the indefinite expressions of outer and inner, which vary constantly in the changing attitudes of the limb.

RADIALIS Arteria, is the artery of the wrist, in which the pulse is commonly felt. See ARTERY.

RADIALIS Carpi Extensor, Longior & Brevior. See CARPI.

RADIALIS Carpi Flexor. See CARPI.

RADIALIS Extensor, Longior & Brevior, synonym of the extensor carpi radiales, longior & brevior. See CARPI.

RADIALIS Internus, a synonym of the flexor carpi radialis. See CARPI.

RADIALIS Nervus. The large nerve which goes behind the humerus, between two heads of the triceps, is called radial by some anatomists; others give this name to the nerve which lies parallel to and over the brachial artery. The first of these is called also the muscular spiral nerve, the second the median. See NERVE.

RADIALIS Vena, the vein corresponding to the radial artery. See VENAE.

RADIANT Heat. See HEAT.

RADIANT Point, or Radiating Point, is any point of a visible object, whence rays proceed.

Every radiant point diffuses innumerable rays all round; but only those radiants are visible, from which right lines may be drawn to the pupil; because the rays are all right lines.

All the rays proceeding from the same radiant continually diverge; the crystalline collects or reunites them again.

RADIATED, in Botany, an epithet applied to round flat flowers, confluting of a disk, and a single row of longish pointed leaves, ranged all around it in manner of rays, or spokes.

Radiated flowers are properly such as have several semi-florets set round a disk, so as to resemble a radiant star; such are daisies, chamomile-flowers, sun-flowers, &c. These are sometimes also called radiated disco-flowers.

A radiated flower has two parts; its middle part, which is called the disk, and which is wholly made up of florets; and the other part, which is called the circle or border, which is wholly made up of semi-florets, or else of plain flat leaves; but that is less common. The florets and semi-florets both usually adhere to the embryo, and to the thalamus of the flower, being contained in one general cup. These embryos finally ripen into seeds; sometimes furnished with down, sometimes with foliaceous heads, and sometimes without either, and sometimes marginated. Of these seeds some are wrapped round with a kind of capule, others are separated from one another by small perpendicular leaves.

RADIATED LEAF. See LEAF.

The word is also used in speaking of medals, and in heraldry,
RALD

heraldry, where the ancient crowns are called Radiated crowns, coronae radiatus. See Crown.

RADIATION, in Physics, the action of a body diffusing rays of light as from a centre.

Every visible body is a radiating body; it being only by means of its rays that it affects the eye.

The surface of a radiating body may be conceived as consisting of radiant points.

Radiation, Place of. See Place.

Radiation, or Irradiation, is also used by some authors to express the manner of the action of the animal spirits; on a supposition that they are diffused from the brain to all parts of the body, through the little canals of the nerves, as light is from a lucid body. But in lieu of a radiation, the moderns rather incline to the opinion of the circulation of the spirits.

RADICAL, Radicalis, in Physics, &c., something serving as a basis or foundation; or which, like a root, is the source or principle whence any thing arises.

The schools talk much of a radical moisture inherent in the seeds of all animals, which nourishes and preserves the vital heat or flame, as oil does a lamp; and which, when exhausted, life is extinguished.

Dr. Quincy observes, that this radical moisture is a mere chimera; unless we thereby mean the mass of blood, which is the promptuaty whence all the other juices and humours are derived; and which, while it circulates, fulfils life, &c.

In grammar, we use the term, radical words, for roots and primitives; in opposition to compounds and derivatives.

In the Hebrew language, the letters of the alphabet are divided into radial and fervile. The first constitute primitive or original words, which, by a significant metaphor, are called roots. All the 22 letters of the alphabet may be radicals; i.e., primitive words may consist of any of these letters; but the following letters properly claim this title, because they can never be fervile: aleph, bet, gimel, dalet, he, vav, zayin. Of whatever letters any word consists, it must at least contain one of a radical character. (See Root.) For an account of the fervile letters, see Servile.

Radical Numbers, Numeri Radiculares, in the Italian music, are 2, 3, 4, 5, 6, 7, 8, 9, and sometimes 10, which are often met with in musical compositions, to denote the accords of the thorough basses: 2 stands for the second and its duplicates; 3 for the third; 4 for the fourth, &c.

Radical Leaf, among Botanists. See Leaf.

Radical Sign, in Algebra, the sign or character of the root of a quantity.

\( \sqrt{\cdot} \) is the character of radicality, and expresses the square root;

\( \sqrt[3]{\cdot} \) the cube root, &c.

RADICANS, in Botany, rooting, a term applied to a stem which throws out fibres as it extends itself, whether those fibres be true radicles, by which the plant imbibes nourishment, and is generally increased; or whether they serve only for the support of the stem against walls, rocks, or neighbouring trees. Of the first kind, the Strawberry affords a familiar example; of the latter, the Ivy, the Virginian Creeper (Hedera, or rather Pitts, quinquifolia), and the Bignonia radicans, are instances.

Radication, the action by which plants take root, or throw out roots, &c.

The French Royal Academy of Sciences have made a great number of curious observations on the germination and radication of plants.

RADICLE, in Agriculture, that part of the seeds of plants which, upon vegetating, becomes their nacient roots.

It is, in fact, the main organ or medium of nutrition, and the means by which food is imbibed or drank up from the surrounding soil or earth. The radicles, together with the leaves, therefore, constitute the absorptive organ of plants. See Radicula, and Root.

RADICOFANI, in Geography, a town of Etruria, near which are two castles, one built by Didier, last king of the Lombards, and the other by Cofno I.; 55 miles S. of Florence.

RADICONDOLO, a town of Etruria; 24 miles N.E. of Florence.

RADICULA, in Botany and Vegetable Physiology, the radicle, or fibre of the root. (See Root.) This term is used by Dillenius, in his Nova Genera, 121. t. 6, as a generic name, for a set of plants referred by Linnaeus to Sisymbrium. See that article.

RADI Prannon Quadrivius, in Anatomy, a muscle of the fore-arm. See Pronator.

RADI Prannon Teres. See Pronator.

RADI Supinator Brevis, 1 musculi of the fore-arm. See Radi Supinator Longus. See Supinator.

RADI Prannon Teres. See Pronator.

RADI Supinator Brevis, 1 musculi of the fore-arm. See Radi Supinator Longus. See Supinator.

RADI Prannon Teres. See Pronator.

RADI Supinator Brevis, 1 musculi of the fore-arm. See Radi Supinator Longus. See Supinator.

the generic character and name, as well as in his reference to Linnaeus. The calyx is many-cleft, not composed of four distinct leaves; the plant has hardly any thing of the aspect of a Linum, and therefore cannot properly be called Linide; neither has it been published as a genus, under the name of Radula, by Linnaeus, as Gmelin’s reference to the 12th edition of Syll. Nat. indicates.

RADIONIETER, a name which some writers give to the radius albinomus, or Jacob’s staff. See FORESTAFF.

RADIISH, in Botany. (See RHAPANUS.) The radish is much grown, according to the author of the Agricultural Survey of the County of Kent, on the belt rich loamy soils of the Isle of Thanet, and in Kent, for the supply of the London feedmen. The roots usually cultivated for this use are, the early short top, the falcum, and the turnip-rooted radish.

The land for the growth of this sort of crop should be in a fine state of preparation, by being ploughed to a great depth in the early part of the winter, and broken down well down by harrowing, so as to render it perfectly clean from weeds, being previously filled with well reduced manure. The ground being brought into this fine condition, the feed is down on furrows about ten inches apart, in a dry time in the month of March, about two to three bushels per acre. And as soon as the plants appear, every other row is cut up with a horeshoe, leaving the rows twenty inches apart. When the plants get two or three rough leaves, they are hoed in rows, and are then kept clean by repeated horse and hand-hoeing, when necessary, leaving the plants at about eighteen inches distance. It is added, in the above Report, that the crop is seldom fit to reap till October, and sometimes is out in the fields till Christmas, without receiving injury from wet weather; it being necessary that it should have much rain to rot the pods, that it may thraw well. In respect to the produce, it is from eight to twenty-four bushels per acre; and it is sold to the London feedmen, who send it to all parts of the kingdom for retailing to the gardeners.

It is probable that this sort of crop might be grown in many other districts near the metropolis, or other large towns, with equal success, where the soil is of a rich loamy nature, as it is very fit in its culture, and requires but little labour or trouble. As it is necessary for it to remain out such a length of time, however, it will be proper, especially in wet seasons, to keep the stems from falling too much upon the ground, as they and the feed may be injured by being too much in contact with it. If kept up in this way, the stalks, feed-hulks, and other offal parts, may also form a good cut food for some sorts of live-stock, as is the case with some other similar sorts of crops.

RADISH, Horse. See CUCUMIS Annuus.

RADIUS, in Anatomy, that bone of the fore-arm which extends from the humerus to the wrist, in the line carried from the external condyle of the former bone to the thumb. See EXTREMITIES.

RADIUS, Dislocations and Fractures of. See Fracture and Luxation.

RADIUS, in Botany and Vegetable Physiology, means the aggregate marginal florets, of compound flowers, each generally of an oblong form, and all spreading from the centre, or disk, like rays. Such are the white florets of the Daizy, and blue, purple or red ones, for the most part, of the Aster. The usual shape of the limb or border of such florets is ligulate; either linear, or elliptical; rarely, as in Ackeria, short and roundish; the extremity having three or five teeth. In some compound flowers the radius consists of tubular florets, as in Cirsium, and those are usually dilated of organs of fruitation. The ligulate radiant florets above-mentioned are either female, producing perfect seed; or they are abortive, with more or less imperfect traces of a pistil. Many of them have no signs of a style or stigma, but none is without so much of a germen, as serves for the bails, that supports the petal itself.

A radius is occasionally alluded to some flowers, naturally dithef of one, as in the genus Bidens, each species of which, by such an acquisition, becomes a Coreopsis, and changes its order in the Syngenesia, from Polygonum aquatilis, to P. superflius. This change is an approach towards a double flower, in that class; being a transformation of a certain number of the perfect, or united, florets into female ones. If such a transformation be total, and all the tubular florets become ligulate, the whole flower is double, and unproductive of seed, like the double Chamomile.

RADIUS, Ray, in Geometry, the semidiameter of a circle; or a right line drawn from the centre to the circumference.

The word is derived from the Greek ῥάδιον, rods. Flata uses the word radius, for a farrow.

The radius is also called, especially in trigonometry, sinus radius ; the whole line.

It is implied in the definition of a circle, and it is apparent from its construction, that all the radii of the same circle are equal.

RADIUS, in the Higher Geometry, Radius of the evolute, Radius circumscribed, or Radius circuli, called also the radius of concavity and the radius of curvature, is a right line representing the thread, by whose evolution from off the curve on which it was wound, the curve is formed; or it is the radius of a circle that has the same curvature in a point of a curve with that of the curve in that point. See Curvature and Evolute, under which articles the method of finding this radius may be seen.

RADIUS Albinomus, an instrument usually called Jacob’s staff, the crofs-staff, or fore-staff.

RADIUS, in Optics. See RAY.

RADIUS, in Mechanics, is applied to the spokes of a wheel; because filling like rays from its centre.

RADIUS Vector, is also used for a right line drawn from the centre of force in any curve in which a body is supposed to move by a centripetal force, to that point of the curve where the body is supposed to be. See CENTRAL Force.

RADUS, among the Romans, a name given to the iron rod with which the boys rolled the trochee.

RADIUS Articulatus, in Natural History, a name given by Mellius, Gmelin, and some other authors, to a kind of figured fossils, of which there are a great many very different species, some of which have been described by authors among the belemnites, under the names of alveoii belemnitarum. Mr. Gmelin, who has taken great pains to inform himself, as well of the nature and figure of these stones, from the subjects themselves, as of their history, and the various accounts of them from other authors, obferves, that the place where they are most frequent is Sweden, and that there they are no where so common as in the isle of Oeland. Volkman figures some also which he found in Silefia, and Helwing others which he collected in Prussia: he also found great numbers of them himself in Russia.

They are usually imbered in lime-lime, and though at first light they may all appear alike; yet, on a careful examination, they will be found to differ very greatly. The most obvious general distinction, established by Gmelin, is that some of them are fragrant, and others crooked. The straight ones may be divided into two genera. The first of these comprehend, according to this gentleman, two species; the first smooth, and with a converging alveolus. The
The regular and nice configuration of these bodies shews very plainly that they cannot be of mineral origin; but the several patellæ of which each is composed, the sphenoculus of communication, obvious in several, and the shelly matter yet found remaining on many, prove them to have been once shell-fish of the univalve or tubular concomrated kind; the description of which, so far as it can be gathered from these remains, must have been this. The shell must have been either cylindric or conic in figure, of a smooth surface, and divided into several chambers or cells; but this for the septa which form the concameterations are not continued and whole, but in some part of the periphery are cut in, in the shape of a crescent. Through these crescents, which, standing all together, make a continued canal, there has cut another shelly body of a cylindric or conic figure, also divided into concameterations, and that in such a manner, that the septa which form the cells are pierced with a small aperture on one side, which grows gradually smaller as the shell extends in length; and finally, through these apertures, in the concameterations, there palpates another shell pointed at the end, and, like the rest, divided into its concameterations, and pierces along its middle with a sphenoculus. 

RAD IX, in Botany and Vegetable Physiology. See Root. 

RADIX is used among some anatomists for the sole of the foot. 

RADIX CARLO SANIO ; this root is found in temperate soils, in Mechocan, a province of America. Its bark is easily separated from it; is of an aromatic smell, and of a bitter and somewhat acid taste. The root itself consists of very slender fibres, which are easily separated from each other. The bark is accounted sordid, and corroborates the stomach and gums; if chewed, it procures an agreeable breath. It is good for scurvy, cataracts, epilepsy, halitancy deliveries, and removing hernias, and the small-pox, if taken either in powder or in the form of a decoction. The Spaniards have called it by the name of St. Charles, on account of its uncommon virtues. 

RADIX ENTRACHORN, the root of the entrochon, a name given by some authors to a fossil substance, usually found among the entrochon, and seeming to have been the basis from which they have grown. It is plainly a part of the stella marina arborosecns petrified, as those stones also are. This fossil is rarely found whole, but the fragments of it are very common. When entire, it is about the size of a walnut; the top of it being flat, and in some degree reminding the end of an entrochon, with a central hollow, but not having the leaf appearance of the rays of those bones. These fossils, though not properly judged of as to their origin, have yet been described by a great number of authors. Agricola, in particular, compares the form of them to a wheel. The body of this kind well resembles indeed the nave of a wheel, the shape of it being conical toward one end, till you come to the top, and then a little flattened, with a hole in it. There is also a like hole in the opposite broad end of the same fossil, seeming fit for an axle to pass through; and there are five hollow fillets, or feet, inclining sideways, at equal distances from the broad bottom, and equally carried on in the same direction, so as not amiss to represent the spokes. At the end of each of these rays or spokes, there is a hollow, of the same nature and with those in the middle of the common entrochon, but this is cut across, by a seam, or break of the same bones, which parallel directly over its centre, and covers about a third part of it; this goes no farther than the mouth of the hole, but it cuts it into two, and swells it in the form of two eyes. These radii or spokes are very seldom found so perfect as here described. Liller mentions them as being formed like crescents at the end, which may very easily happen from the breaking off a part of the terminating portion. 

Phil. Trans. N° 129. 

RADIX ALBA, a word used by Dioscorides, to express the root of the dracunculus. 

RADIX, among Grammarians. See Radical, and Root. 

RADIX, in Mathematica, the same as root; but used in a different sense by different authors: we say the root of an equation, but the radix of a fyltem of logarithms, the radix of a series, the radix of notation, &c. meaning in all these cases the fundamental quantity on which the fyltem is constructed, or that whence it has been derived, or that by means of which all other things of a like kind are compared. 

RADIX OF A SYLTEM OF LOGARITHMS, is that number which involved to the power denoted by the logarithm, is equal to that number. Thus, under the article LOGARITHMS it is shewn, that if $r^x = a$, then $x$ is the logarithm of $a$, and $r$ is called the radix of the fyltem. This radix in the common or Briggs's logarithms, is 10, and in the Neperian or hyperbolic logarithms, it is 2.71828128, &c. and generally the radix of any fyltem of logarithms, is that number whose logarithm in that fyltem is unity. 

RADIX OF A SYLTEM OF NOTATION, is that number which indicates the local value of the figures, and is in all fyltems represented by a unit and cipher (10), which is ten in the common fyltem, two in the binary fyltem, three in the ternary, twelve in the duodecimal, and so on. See NOTATION. 

RADIX OF A SERIES is used, by some authors, as a term of comparison between any finite function, and its expansion or development: thus, the 

\[
\text{of } 1 - r + r^2 - r^3 + r^4 &c. \text{ is } \frac{1}{1 + r} \\
\text{of } 1 - \frac{1}{2} + \frac{1}{4} - \frac{1}{8} + \frac{1}{16} &c. \text{ is } \frac{1}{1 + \frac{1}{2}} \\
\text{of } 1 - 1 + 1 - 1 + 1 &c. \text{ is } \frac{1}{1 + 1} \\
\text{of } 1 - 2 + 4 - 8 + 16 &c. \text{ is } \frac{1}{1 + 2} \\
\text{of } 1 + x + x^2 + x^3 + x^4 &c. \text{ is } \frac{1}{1 + x} \\
\end{align*}
RAD

of $1 + 2x + 3x^2 + 4x^3 + 5x^4 \text{ &c. is} \ \frac{1}{1 - x}$

of $1 + \frac{x^2}{2} + \frac{3x^4}{8} + \frac{5x^6}{16} + \text{ &c. is} \ \frac{1}{1 - x}$

See Dr. Hutton's Tracts, vol. i. p. 9. See also our article Series.

RAD-KNIGHTS. See REDMANS.

RADL, in Geography, a mountain of Stiria; eight miles S.S.W. of Landperg.

RADLER, See, a lake of Carinthia; six miles N. of Saxenburg.

RADLSTEIN, a town of the duchy of Carniola; six miles W. of Landkras.

RADLZHAL, a town of Andria; nine miles E. of Krottan.

RADMANS. See REDMANS.

RADMANSO, in Geography, a small island in the Baltic, near the coast of Sweden. N. lat. 59° 45'. E. long. 18° 44'.

RADNAGUR, a town of Bengal; 32 miles S. of Burdwan.

RADNITZ, a town of Bohemia, in the circle of Pilzen; 10 miles N.E. of Pilzen.

RADNOR, New, or Muss-Tyd, a borough and market-town in the cemwld of Swydd Wynogion, Cantref y Clawdd, (now called the liberties of the town of New Radnor,) county of Radnor, South Wales, is situated near the river Somer- gill, at the distance of seven miles N.W. from Kington, and 156 miles W.N.W. from London. In remote times, this town was a place of great importance, as appears from its having given name to the county, but it has now dwindled into comparative poverty and insignificance. Caradog informs us, that about the year 990, Meredydd ab Owain delivered Radnor, in a ferocious contest with his nephew, who had been affiliating the English to ravage South Wales. It recovered, however, from this disaster, and continued to flour- ish till the union of Wales with England, when it began to decline, in consequence of its ceasing to be fortified and gar- risoned as a frontier town. Before that period, it was sur- rounded by a lofty wall, and a deep moat, fome remains of which are distinctly visible on the west and south sides. The walls, when standing, are traditionally said to have been of great height. The area included by them was an oblong square, containing about twenty-six acres of ground, laid out into three longitudinal streets, which were intersected by five transverse ones. Of these at present severa! none buildings; and others are only foot paths. But though thus decayed, Radnor still preserves its privileges as a borough. The corporation consists of a bailiff, twenty-five capital burgesses, two aldermen, a recorder, a coroner, a town-clerk, and other inferior officers. The bailiff and aldermen are chosen annually from among the capital burgesses, and are judges of the peace. The bailiff of the preceding year is also a justice of the peace; and there are besides three additional persons nominated out of the capital burgesses, who are invested with similar authority. The districts over which they preside, and superintend, the jurisdiction of the county magistrates, is considerable; comprehending a circle round the town nearly ten miles in diameter. The bailiff's courts and the petty sessions are regularly held every Monday, when the bailiff, aldermen, and town-clerk attend to transact business relating to the borough, and have power to determine all suits for sums under forty shillings. The quarter-seions for the borough are held on the Monday after the county quarter-seions at Preiteigne; and the sheriff's county courts, for the recovery of small debts, are held every alternate month here, and at the town last mentioned. The representative for the borough is chosen by the burgesses of New Radnor, in conjunction with those of the boroughs of Knighton, Radnor, Cefn Llwyd, and Crwles; the bailiff being the returning officer. As nothing but the circumstance of receiving parochial relief disquali- fies any person from becoming a burgess, the number of voters is considerable; those of New Radnor are supposed to exceed 300, and the whole number, including those of the contributory boroughs, is estimated to be about 1300. To be a capital burgess of New Radnor, however, actual residence within the jurisdiction is essential, which is not the case as to the contributory boroughs: and if a capital burgess becomes non-resident he loses his privileges as such. A benefit so- ciety, established here in 1778, at present consists of above 100 members, who hold their annual meetings on the 6th of January.

Weekly markets were formerly held here on Tuesdays, but these are, at present, only nominal, notwithstanding some late attempts to reform them. There are still, however, five annual fairs, and there is also an annual wake on the third Sunday in the month of August. The parish of Radnor is divided into three portions, of which the town of New Radnor is the principal, containing, according to the parliamentary returns of 1811, 75 houses, and 360 inhabitants. The public buildings here are the town-hall, the prison, and the church. The last consists of a nave, south aisle, and chancel, with a tower at the west end.

Radnor castle stands on an eminence commanding the town. Of this once majestic pile, a few fragments of walls only remain, but the entrenchments are still entire; the outer ward, called Balli-Glas, or the Green Court-Yard, is yet distinct from the inner one, or keep, and is nearly in its original form. In 1773, on digging within the area of this castle, six or seven small "Gothic arches of good masonry were discovered," besides a variety of ancient inumaments. The forest of Radnor extends several miles to the north of the town, covering the slope of a lofty eminence, from the summit of which are very extensive prospects. The principal seats in the vicinity are Downton-hall, the seat of Percival Lewis, esq., and Harpton-court, a seat belonging to Thomas Frankland Lewis, esq. Both these manoros are surrounded by beautiful scenery, and are highly ornamental to this district. About two miles westward from the town is a celebrated water-fall, called Water-break-its-neck, seventy feet in perpendicular height; but it is extremely defective in water, except during the time of floods, when the effect produced is truly grand. At the western extremity of the parish is an entrenched dyke, which formerly extended across the whole vale of Radnor; War-clofe, a field to the eastward of the town, is traditionally said to have been the scene of some military contest, but no particulars respecting it are preferred.

Old Radnor, or Pen-y-Craig, is a small village, situated about three miles to the south of New Radnor. Camden supposes it to have been the Magnos of Antoninus, which was garrisoned by the Phcenician regiment in the reign of Theodosius the younger; and there seems every reason to believe that it was a place of note in the Romain-British pe- riod. The Roman road passed close to the base of the hill upon which the village stands. The church here is a vener- able old edifice of stone, with a massive square tower at one end. A curious screen, richly carved in wood, extends across the nave and side aisles. Here are various monuments to the memory of members of the Lewis family of Har-pton. Carlyle's Topographical Dictionary of Wales, 4to. 1815. Lipincom's Tour through Wales.
RADNOR, a small pleasant town of America, in Delaware county, Pennsylvania. The place was originally called "Amiltel" by the Dutch, who began to build here. The number of inhabitants is 925.

RADNOR, a town of South Carolina; 10 miles S.W. of Edmondbury.

RADNORTH, an inland county of South Wales, is bounded on the north by the counties of Montgomery and Salop, on the east by the county of Hereford, and on the south and west by the counties of Brecknock and Cardigan. According to Mr. Clark, it contains 510 square miles, or 131,500 acres; and is politically divided into fifteen hundreds, and fifty parishes; some of which are within the diocese of Hereford, and the remainder within that of St. David's. The parliamentary returns of 1811, state the number of its houses at 4194, and of its inhabitants at 28,500. It sends two members to parliament; one for the county, and one for the borough of New Radnor, with its contributary boroughs. The face of the country is extremely mountainous and bleak; in every part of it, but it is intersected by several valleys, which are watered by the Wye, the Teme, the Lugg, and the Severn, and the Ednow, and their respective tributary streams. These valleys afford a considerable extent both of meadow and arable land; especially the Vale of Wyse-side, and the Vale of Radnor, some portions of which are very fertile, and have a good soil and a congenial climate. In the other parts of the county, however, a barren soil, and a chilly atmosphere, are the predominant characteristics. Nearly two-thirds of its whole extent being either in a state of commonage, or lying wholly waste, agriculture has hitherto made little comparative progress here. Cattle and sheep constitute the chief produce of the county. The number of the latter is indeed very great. Hence Radnorshire is famed for its supply of wool; but notwithstanding this circumstance, singular to say, the manufacture of woolen goods is totally disfigured. The raw material is sold to the manufacturers of the north, by whom the inhabitants of this county are in return furnished with cloth.

Radnorshire contains three market-towns; Presteigne, Radnor, and New-Radnor. The market at the latter, however, is only nominal. The county courts are held at Presteigne, which is now the most important and flourishing town in the county. (See PRESTEIGNE.) The chief remains of antiquity within its limits is Offa's Dyke, which commences near the river Wye, near Hay, skirts the counties of Radnor and Hereford, and passes into Montgomeryshire at Pwll-y-Pyod, a hamlet on the road between Bishops-castle and Newtown. The only religious house in the county was the abbey of Cwm Hir, founded in 1143, for monks of the Cistercian order, by Cadwathelan-ap-Madoc, which, at the dissolution, was valued at 32l. 17s. 4d. per annum. Of this monastery a considerable part of the buildings is yet standing, though in a very ruinous and dilapidated condition. In his Itinerary, (vol. i. p. 121, 1) speaks of its church as the longest in Wales, and informs us, that it was "spoiled and defaced by Owen Glendower." The principal caffles in Radnorshire were those of Colewine, Tynhont, Aberedow, or Aberedvy, Ewennys, Radnor, Radnor, and Pain's-castle. Several antiquaries, among whom are Camden, Gale, and Ward, place the Roman station Magnes, or Magna, at Old Radnor, as is mentioned above; but Baxter contends that it should be fixed at Ledbury, in Herefordshire, and Harris at Gaer, near Brecknock. In this county, particularly on the summit of Gwladolin hill, are several of tchole collections of stones called in South Wales "larnaen, in North Wales, "kernedels, in Scotland, "cairns, and in Ireland, "duns.

RAF

Radnor was erected into an earldom by Charles II., in the person of John Roberts, lord Roberts of Truro, but that title became extinct in 1757. It was revived, however, in 1795, in the person of William Bouvier, baron Longford, and vicount Folkestone, whose son Jacob, now earl of Radnor, enjoys his privileges. of Caracas; 40 miles S. of Caracas.—Also, a town of South America, in the province of Moxes; 210 miles E. of Santa Cruz de la Sierra la Nueva.—Also, a town of New Navarre; 105 miles S.W. of Caza Grande.

R. RAFAH, a town of Egypt; 57 miles N.E. of Catech.

R. RAFALES, a small island in the gulf of Finland. N. lat. 60° 29'. E. long. 26° 12'.

R. RAFAELLE DA UBINO, in Biography. See R. RAFFLE.

R. RALLING, a fort of game with three dice, in which he who throws the greatest pair, or pair royal, in three casts, wins the prize or stake.

The word probably comes from the base Latin, risiiare, to risit, fluster, take all away.

The raffle is properly the doublet or triplet: a raffle of acts, or duces, carries it against mere points.

Raffling is also used when a company of perfous club to the purchase of a commodity, or make small deposits, amounting in the whole to its full value; and he that throws the highest on three dice, or who has the highest number by means of balls thrown on a bagatelle or porte-bello table, takes it.

R. RAFFICA, in Geography, a town of Asiatic Turkey, in the government of Diarbekir; three miles S. of Raca.

R. RAFLUNDA, a town of Sweden, in the province of Skone; 17 miles S. of Christianstad.

R. RAFFNIA, in Botany, a genus of plants, separated from the Linnaean Crotalaria and Liparia, augmented with several new species from the Cape, and named by its author, professor Thunberg, in the second part of the preface to his Prodromus Plantarum Capenum. De Theis is completely in the dark as to the peron commemorated in this name, who can be no other than Mr. C. G. Rafn of Copenhagen, author of a Flora of Denmark and Holstein, in the Danish language, publifhed in the years 1796 and 1800, in octavo, making two volumes, which include the first ten classes of the Linnaean sytem. We know not whether any more has appeared. The same botanist has written a work on the physiology of plants; and several papers for the Academy of Sciences at Copenhagen. See Sims and König's Ann. of Bot. v. 1. 6.—Thunb. Prodr. 132. pref. n. 48. Willd. Sp. Pl. v. 3. 949. Ait. Hort. Kew. v. 4. 261.—Cliffs and order, Dianella Decandria. Nat. Ord. Papilionaceae. Linn. Logeminiaga. Juif.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, five-cleft, ringent; the upper lip in two broad dilatant segments; lower Divaricating, in three acute ones, the middle one smalllet. Cor. Papilionaceous. Standard large, heart-shaped, acute, spreading, deprefsed at the sides. Wings ovate, about half as long as the standard. Keel acute, the length of the wings. Stam. Filaments ten, all united into a linear tube, split along the base; five of them rather the shorter; anthers fimple. Pflit. Germin flanked, linear; style fimple, bent upwards at nearly a right angle; stigma obtuse. Peric. Legume flanked, oblong-lanceolate, compressed, of one cell and two valves. Seeds ferior, flanked, roundish-kidney-shaped.

Ed. Ch. Stamens all united. Calyx ringent; upper lip divided; lower Divaricating, in three segments, the middle one smalllet. Legume flanked, lanceolate, compressed.

Obs. The first species in Wildenow, Crotalaria perforata, Crotalaria perforata of Linnaeus, figured in Smith's' Infests of Georgia, v. 2. t. 67, is Baptisia perforata of Brown, in Ait. Hort. Kew. v. 3. 5, a genus adopted from Ventenat, and belonging to the Descandria Monogynia.

1. R. amplexicaulis. Orbicular Rafния. Thunb. Prodr. 123. Willd. n. 2. (Crotalaria amplexicaulis; Linn. Sp. Pl. 1009. Genista perfoliata, orbiculati foliis; Sch. Theaur, v. 1. t. 24. f. 5. Linn.)—Leaves reticulated, orbicular, clasping the stem, alternate; the floral ones opposite, coloured.—Native of the Cape of Good Hope. A smooth, handsome, branched, Purpure; clothed with entire leaves, from one to two inches acrod, finely reticulated with innumerable veins; the upper ones, which accompany the flowers, smaller, and pale yellowish. Flowers solitary, nearly femail, yellow, smaller than the floral leaves.

2. R. elliptica. Elliptical Rafния. Thunb. ibid. Willd. n. 3, excluding the reference to Andrews.—Leaves slightly veined, elliptic-ovate, acute; alternate; the floral ones opposite, not longer than the flowers.—Native of the Cape. Confounded by Linneaus with the foregoing, from which it differs in having much smaller leaves, femail, not clasping the stem, quite defoliated of reticulated veins. Flowers of a deeper yellow, as long as the floral leaves.

4. R. triflora. Three-flowered Rafния. Thunb. ibid. Willd. n. 5. Ait. n. 1. Venten. Malm. t. 48. (Crotalaria triflora; Linn. Sp. Pl. 1004. Curt. Mag. t. 482. Borbonia cordata; Andr. Repof. t. 31, excluding the fynonym. Raffnia.)—Leaves ovate, smooth. Branches angular. Stalks single-flowered, three together.—Native of the Cape, where it was gathered by Sparrmann and Thunberg, and from whence its seeds were sent to Kew garden, in 1786, by Mr. Francis Maffon. The plant is biennial, requiring to be sheltered in winter, and flowering in June and July. Stem branched, about a yard high, moft leafy in the upper part, smooth, and of a glanceus green, as well as the leaves, which are numerous, alternate, almost femail, more or less ovate, but varying in size and breadth. Flowers abundant at the summits of the branches, large, yellow, axillary, flanked, three together, the floral leaves smaller than the reft, and often tinged with purple.

5. R. opposita. Opposite-leaved Rafния. Thunb. ibid. Willd. n. 6. (Crotalaria opposita; Linn. Suppl. 322. Liparia opposita; Linn. Syll. Veg. ed. 13. 554. Spartium capense; Sp. Pl. 995. Cytisus capensis; Berg. Cap. 217.)—Leaves elliptic-lanceolate; the upper ones mostly opposite. Flowers lateral, on short solitary stalks.—Native of the Cape, apparently unknown in our gardens. Linnaeus and his son confounded many different things under this species, some of which being marked in their herbarium as having been gathered by Thunberg, we presume to be among those he has defined; yet it is not posilive to determine them all by his short characters, several of which unfortunately contradict the specific names. The flem of the present is described by the younger Linnaeus as simple, he considering as floral-falks the copious, alternate, leafy branches, three or four inches long, on which one or two pair of the lower leeters are opposite; the proper floral leaves, like those of the stem, being alternate: all the leeters are elliptic-lanceolate, or somewhat obtuse, acute, entire, fingle-ribbed, an inch or more in length. Flowers either lateral or axillary, among the uppermost leaves, solitary, each on a simple flalk about the length of its calyx. Corolla yellow, not half so large as the last species.

n. 7.—"Leaves lanceolate, alternate or opposite. Flowers terminal."—This and all the following were gathered by professor Thunberg, at the Cape. In the Linnean herbarium is a specimen, by whom gathered does not appear, which seems to answer to the above character, (except the Lesser being linear-lanceolate,) and which perhaps explains the paradoxical contrariety between the specific name and character. In this specimen the flowers are really terminal, being solitary at the ends of copious, short, leathery, lateral branches, which are axillary. The whole flower has a Hypop-like aspect.

8. R. ficata. Spiked Rafnia. Thunb. ib. Wildl. n. 9.—"Leaves lanceolate, alternate. Flowers axillary, racemose."—Of this species alone, it seems, Willdenow had seen a dried specimen, and we regret that he did not give us some account of it.

10. R. filifolia. Thread-leaved Rafnia. Thunb. ib. Wildl. n. 11.—"Leaves linear-lanceolate, alternate. Flowers axillary."—The Linnean herbarium contains two specimens, specifically different, which we premise belong to this and the last, but no human sagacity can appropriate them; except that one of them, with large and seemingly purplish flowers, having rather the narrowest leaves, may be taken for filifolia. This is marked as gathered by Thunberg. The other has much smaller and yellow flowers. The stem is round in both.

11. R. retroflexa. Bent Rafnia. Thunb. ib. Wildl. n. 12.—"Leaves ovate. Branches reflexed backwards and forwards."—A specimen from Thunberg answers to the above name and character, except the leaves being rather linear-lanceolate than ovate. Their colour is somewhat leathery. Flowers mostly terminal, solitary, on short stalks, with an awl-shaped bract, or abortive leaf, at the base of each stalk.

All the species turn more or less black in drying. For Rafnia rotula of Ventenat, Malmaison, t. 53, see Templetonia hereafter, and Ait. Hort. Kew. v. 4, 269.

RAFSO, in Geography, a small island on the E. side of the Gulf of Botnia. N. lat. 61° 37'. E. long. 21° 12'.

RAFSUND, a town of Sweden, in the province of Upland; 28 miles S.E. of Erefon.

RAFT, in Sea Language, a fort of float formed by an assemblage of various planks, or pieces of timber, fastened together side by side, so as to be conveyed more commodiously to any short distance in a harbour or road, than if they were separate. The timber and planks, with which merchant-ships are laden in the different parts of the Baltic sea, are attached together in this manner, in order to float them off to the shipping.

This means of conveying timber to navigable situations may be advantageously practiced in many places. It is found of great utility in many of the northern parts of the island as well as others, near canals and waters, where a cheap conveyance for such articles is required.

The balsa or cataraman used by the Indians and Spaniards in South America, is only a raft made of the trunks of the balsa; for an account of which, see the article Boat.

They have one mast, on which is hoisted a large square sail; and a pair of sheets, whose heels rest on each side the raft. When a fore-and-aft sail is set, a pair of sheets isrigged forward. These rafts were the forerunners of vessels of a better construction, thought of and what is rather surprising, they are made to sail with foul winds, and fleer, as well as any other kind of vessels, by means of an invention similar to, and perhaps the original of, that which is now called "a flying-keel." They have for this purpose rafts about ten feet long, and fifteen to eighteen inches wide, which slide vertically in the spaces between the trunks which form the raft. It is only nec overflow to immerge them more or less, and put down a greater or less number at the fore or after part of the raft, to make it either luff-to, or fall-off from the wind, tack, veer, lie-to, and perform every necessary manoeuvre. The number of these planks is five or six, and if one of these planks be drawn up forward, the raft will keep away; and, if one is raised abaft, it will come to the wind. This sort of raft, from the simplicity of its construction, might perhaps be well adapted to many cases of emergency, after shipwreck upon coasts, destitute of all other materials for ship-building.

RAFT-PORT, in a Ship, a square hole cut through the foothocks of some ships, immediately under the counter, to receive the planks or pieces of timber which are brought to house her for transportation; and which, on account of their great length, could not be received aboard otherwise.

RAFTERING, in Agriculture, a provincial term used for a sort of ploughing in narrow ridges, or small ridgets. It is useful for expelling a large surface of earth to the influence of the atmosphere.

RAFTERS, in Building, are pieces of timber, which, standing by pairs on the rafter-piece or rafter-piece, meet in an angle at the top, and form the roof of a building.

It is a rule in architecture, that no rafters should stand farther than twelve inches from one another.

For the sizes or scantlings of rafters, it is provided by act of parliament, that principal rafters from 12 feet 6 inches to 14 feet 6 inches long, be 5 inches broad 3 topt, and 8 at the bottom, and 6 inches thick. Those from 14, 6, to 18, 6 long, to be 6 inches broad at the foot, 7 topt, and 7 thick. And those from 18, 6, to 21, 6, to be 10 inches broad at the foot, 8 topt, and 8 thick.

Single rafters, 6 feet 6 inches long, to be 4 and 3 inches in their square.

RAFTY, a provincial term signifying damp and muddy, as corn or hay in a wet leaen.

RAG, or RAKE, among Hunters, denotes a company or herd of young colts.

RAG, or Rag, Roeley, in Mineralogy. See Ferrilite.

Rag, a torn piece of cloth of any sort. See the next article.

Rags, Wealls, as well as the clippings of pitch marks upon sheep, are good manure. The rags should be chopped small, about an inch or two square, and scattered on the earth at the second ploughing; for being thereby covered they will begin to rot by feed-time. They imbibe the moisture of dews and rain, retain it long, and, according to Dr. Home, keep loofe dry folly in a moist state. They formerly cost about fourpence a baffle at London, from whence many loads were sent every year to Dumfrait, which is thirty-three miles, where they are laid on even hill lands, just after the fowing of the corn, allowing to the acre four facks, of six bushels each; they are much higher now, at more than double
double this price, and no quantity of any great account to be procured. See MANURE, and Top-drilling.

The farmers in Oxfordshire make use of rags of this sort, procuring them from London and other places, at the rate of from eight to nine pounds the ton, which, with the carriage, itaied in upon the farms from nine pounds ten shillings to ten pounds. By some they are spread upon the clover lands, by others after their manure, in the proportions of from three or four to six hundred weight to the acre. Tried with dung in this way, in the quantity of seven hundred weight to the acre, the dung is found the better drifting. They are also applied for turnips, for which crop they are ploughed in before the winter, as soon as the wheat-fowing is over: if ploughed in at the time of sowing turnips, they will not work for that crop. Some for this crop give half a coat of rags, and half a coat of sheep-fell. When applied on the clovers they seldom last longer than two months. Others think that half a coat of rags, and half a coat of dung, is the most beneficial method of applying this sort of manure. Some think rags are more durable than any other manure. Rags are occasionally brought from Whitney to this district, at from seven shillings and sixpence to eight shillings and sixpence the hundred weight, and five hundred weight spread upon the acre: they commonly last only one crop, but sometimes for two, and are found superior to any thing for wheat. They are ploughed in, and if the season be very dry, do not answer so well. They are suppos’d to do belt on a summer fallow for this crop.

In Suffolk rags are chiefly of service in the hop grounds, for which they are thought an excellent manure. Very great benefit is said to have been derived from the application of these rags, in contributing to preserve this sort of plantation in a state of constant moisture and vegetation in the dryish season, when grounds which have been manured with dung, have been dried up, and the hop crops have failed. Rags have likewise been found very useful on the moving grounds in some parts of Lancashire, when laid upon them, in a pretty full proportion. When cut or chopped sufficiently small, they readily sink down upon the surface of the land, and do not afford any sort of interruption to the fycythe, while they absorb and keep in the moisture, which is of material benefit to such grassy lands as are inclined to be dry.

RAG, in a Ship. See BOLTS.

RAGAL, in Geography, a town of Germany, in the county of Plunetz; 10 miles E. of Plunetz.

RAGALBUTO, a town of Sicily, in the valley of De- mona; 23 miles S. of Cefalu.

RAGALMATO, a town of Sicily, in the valley of Mazara; 8 miles N. of Naro.

RAGAMMEE, a town of Ceylon, near the W. coast; 58 miles S. of Colombo.

RAGANELLO, a river of Naples, which runs into the gulf of Taranto, near Cistita Mandona.

RAGAPILLY, a town of Hindoostan, in Golconda, near the left bank of the Godavery; 5 miles S.E. of Badrachilum.

RAGATZ, a town of Switzerland, in the county of Sargans; 5 miles S.S.E. of Sargans.

RAGAY, a town on the S. coast of the island of Lu- son. N. lat. 15° 55’. E. long. 122° 40’.

RAGGED, in Heraldry. See RAGULED.

RAGGED Hamlet, in Falconry, is a hawk that hath its feathers broken.

RAGGED Robin, in Botany. See LYNCHIS.

RAGGED Harbour, in Geography, a bay on the E. coast of Newfoundland, being a part of Catalina bay; 2 leagues N. of Catalina harbour. N. lat. 49° 45’. W. long. 55° 40’.

RAGGED Helmet, a small island in the Mergui Archipe- lago. N. lat. 10° 5’.

RAGGED Island, a small island in the East Indian sea, near the island of Paraguay. N. lat. 11° 24’. E. long. 119° 50’.

—Alfo, a small island among the Bahamas. N. lat. 22° 27’. W. long. 77° 18’.

RAGGED Point, a cape on the E. coast of the island of Bornoe. S. lat. 2° 15’. E. long. 116° 40’.—Alfo, a cape on the N. coast of the island of St. Christopher. N. lat. 17° 30’. W. long. 67° 42’.

RAGGIVOLO, a town of Italy, in the department of the Mincio; 19 miles S. of Mantua.

RAGHU, in Hindu Mythology, is the name of the an- cessor of Rama, one of their derived heroes, who is hence sometimes called Raghva, or son of Raghu. Buddha, or Boody, another of the Indian deities, is said to have had a son also of this name.

RAGHWA, a name of the Hindu deified hero Rama, signifying a descendant of Raghu, a warlike character. All these names are full very common among Hindoos: whether confined to the few who, as chiefly worshipping Rama, are called Ramdami, or more extensively given, we are not in- formed. See RAMA.

RAGIAN, in Geography, a town of Perâ, in the pro- vince of Farfiban; 130 miles N.W. of Schiras. N. lat. 50° 40’. E. long. 50° 58’.

RAGLAND, a small village of Monmouthshire, here mentioned on account of its castle, the ruins of which evincing its grandure and magnisificence, command the attention of travellers. During the rebellion it was held for the king, and defended to the last extremity by the marquis of Worcester; 8 miles W. of Monmouth.

RAGMAN’S ROLL, or Ragman’s Roll. See ROLL.

RAGNIT, in Geography, a town of Prussian Lithuania, on the river Memel, endowed with the privileges of a town in the year 1722. Its ancient castle was famous even in the times of Paganism. The knights of the Tenonton order re- built it, with additional works, in 1255; but being destroyed in 1555, it was rebuilt a second time, and called Landfi- huth; but afterwards it obtained the name of Raginit from the river which pusses by it; 56 miles E.N.E. of Köniberg. N. lat. 55° 5’. E. long. 22° 18’.

RAGOGNA, a town of Italy, in Friuli; 16 miles N.W. of Udina.

RAGOOGUR, a town of Hindoostan, in the Malva country, and circur of Kitchwana; 116 miles N.E. of Ou- gein. N. lat. 24° 23’. E. long. 73° 30’.

RAGOTKA, FRANCIS, in Biography, the second of the name, prince of Transylvania, distinguished by his courage and patriotism, was born in 1676, at the castle of Boriš, in Hungary. When he was only a year old he lost his father, prince Francis, and was left to the care of his mother, Helena Sereni, who afterwards married count Te- keli. During his education he was carefully watched by the house of Auloria, and the correspondence with his mother, who had retired to Contantinople, was entirely broken off. He was now suffer’d to travel to most of the courts of Eu- rope, and to contract a marriage with the princess of Helle Rhinefield. Zealously attached to the independence of his country, which was kept in a state of great degradation by the Imperialists, he secretly entered into a negotiation with the French king, Lewis XIV., but being betrayed by one of his confidants, he was arrested, and a charge of treason was preferred against him. The sentence of guilty was soon pronounced, and he was committed to the custody of an officer,
of officer, who, however, connived at his escape, and he arrived in a dragoon's habit at the frontiers of Poland. Here he received assurances of alliance from France, and immediately published an eloquent manifesto, calling upon the nation to free itself from the Austrian yoke. Numbers joined him; being, however, but half armed, he was fearful of trifling his cause in their hands, and withdrew to the frontiers of Poland, where he was joined by fresh recruits. With these he ventured to make some progress; stormed several fortresses; and took a severe revenge upon the Imperialists, who had given no quarter to the Hungarian insurgents.

At this period the crown of Poland was vacant, through the deposition of Augustus by Charles XII. of Sweden, and the Polish chiefs were deficient of placing it upon the head of Ragotzki. But he had no such ambitious views as his great object was to liberate his country, and he refused to desert its cause for any other prospects. He accordingly pursued his successes, and by the reduction of Tokay, obtained the submission of almost the whole of Lower Hungary. So high was his reputation, that the diet of Alba Julia, in 1704, proclaimed him prince of Transylvania, with which dignity he was afterwards solemnly invested. He obtained likewise the title of protector of Hungary, and Lewis XIV. sent to him a public embassy. He soon began to feel the difficulty of supporting a popular insurrection against the arms and policy of a powerful sovereign, as well by the abandonment of some of his allies, as by the defection of his troops. He had another opportunity of giving a refusal to the crown of Poland, which was offered him by the czar Peter, fearing thereby his incoreal attachment to the cause of his country, and he employed all the resources of valor and good conduct to support a declining cause. In 1711, a treaty was concluded between the Hungarian states and the emperor, in which he refused to enter, although the first article secured his life and property, with the title of prince of Transylvania. Mortified by the failure of his patriotic exertions, he withdrew to Turkey, renouncing his great estates, and preferring an honourable poverty to a splendid servitude. He afterwards passed some time in France; then returning to Turkey, he fixed his final residence at the castle of Rodóto, on the sea of Marmora. "There," says his biographer, "a Christian among Mahometans, and a philosopher among barbarians, he tranquilly closed his life in 1735, at the age of 61." He left "Memoirs of his Life," which were published in the "Revolutions de Hongrie," printed at the Hague in 1739. In 1754 there appeared a work, entitled "Testament politique et moral du Prince Ragotzki," the authenticity of which is doubted. Morei.

RAGOUT, or Ragoo, a sauce or seasoning, intended to increase or recover the appetite when languishing, or lofty.

The term is French, but naturalized. It is also used for any high-favored dish, prepared of flesh, fish, greens, or the like, by flewishing them with the addition of bacon, salt, pepper, cloves, and the like high-flavored ingredients.

We have ragoos of beef, of cray-fish, of griblets, of asparagus, of endive, of cocks-combs, of gammon, of celery, &c.

The ancients had a ragout, called *garum*.

RAG-PAVING. See PAVING.

RAG-STONE, a name given by our artificers to a kind of flint, which they use for setting an edge upon knives, chisels, and other tools. It is a greyish-coloured flint, containing a large quantity of talc-kely particles, andipsicately into thin flakes. It is a soft flint, and is used only to finish the setting an instrument after the edge has been prepared by grinding or rubbing the tool upon some other flone of a coarser texture. We have this from Newcastle and many other parts of the north of England, where there are very large rocks of it in the hills. This kind of flone is some districts considerably blended and intermixed with the fulboil, rendering it of a more barren and unfitful quality.

RAGUÉNET, l'Ane, in Biography. In 1702 the publication of a pamphlet, entitled "Parallél des Italiens et des Françoys en ce qui regarde la Musique et les Opéras," by this author, a man of taste and intelligence, who had resided some time at Rome, gave birth to a long, but ineffectual controversy, concerning the degrees of perfection, and superiority of French and Italian music. The book was licenced by Fontenelle, who, in his testimony, that he thought it would be very agreeable to the public, provided they were capable of equity. This declaration, however, did not prevent Frénecule, the continuator of Bonnet's "Histoire de la Musique," from attacking the author and Italian music in a most furious manner, treating both with equal contempt and obloquy.

The French, after this period, seem to have enjoyed their lyce *fonnaçl* in great comfort and tranquillity till 1752; when the performance of Pergolesi's "Serva Padrona" at Paris, by a company of burletta fingers from Italy, set the musical republic in a flame which has not yet extinguished.

There had, indeed, been a *fénation* excited, that was rather turbulent, and tending to a civil war, on the first appearance of Rameau as a dramatic composer in 1733, who, by new harmonies and accompaniments, had given offence to the true believers in the worship of Lulli; but this soon subsided, and the nation not only heard his compositions with rapture, but reverenced him as a "theorist, to whom music was as much indebted as physics and philosophy to Newton."

This little work was published in English in 1709, and has been said to be translated by Galliard. If this worthy professor was the translatior, it was before he had made himself to completely master of the English language, as he appeared to be afterwards, in his translation of "Toil or florid Song." The English of this *parallél* is feeble and inaccurate; many of the notes, however, are good, and manifest a person who had been in Italy, and well knew the state of music in that country, as well as in England, at the beginning of the last century, during our first attempts at operas, before the arrival of Handel.

RAGUER, i.e. The name given by the French sailors to a wind peculiar to the gulf of Alexandretta or Scanderoon, which, rushing from the snowly summits of the mountains, frequently forces ships to drag their anchors several leagues.

RAGULED, or Ragged, in Heraldry, is applied to an ordinary, *c^r* a cross, whose outlines are jagged or knotted.

He barks fable, a cross ragule, or, by the name of Slavoy.

Ragged differs from indented, as the latter is regular, and the former not.

The bearing is very ancient: Julius Caesar gave for his badge, a boar's head, on a ragged staff. Raguled is sometimes also used in the sense of truncated, or capped, and applied to a branch that is lopped from the tree; or a flock lawed from its root.

RAGUN, in Geography, a town of Germany, in the principality of Anhalt-Dessau, on the Mulda; 9 miles S. of Dessau.

RAGUNDA, a river of Sweden, which rises in the lake
lake Storfo, and in the province of Medelpadia, changes its name to Indal.

RAGUSA, a small republic, situated on the eastern shore of the Adriatic, and nevertheless regarded as an Italian state. It has a population of about 56,000 persons, on an extent of 552 square miles. As this state is adjacent to the territory formerly belonging to the Venetians in Dalmatia, its government is regulated on the model of the Venetian aristocracy. Its religion is the Catholic, and its language the Slavonic, though most of the inhabitants speak Italian. The fee is archipelagic, with fix furrags, and its commerce is considerable. The chief magistrate of the aristocracy in this island, called the "rector," is changed every month. Here is also a council of ten, and a great council composed of all the nobles above twenty years of age, and these nominate the "Pregodi," a senate of sixty, which superintends all state affairs, receives and deputes ambassadors, and confers offices. The revenue of Ragusa was formerly estimated at a ton of gold, or about 10,000 florins. This small republic has found it necessary to engage the protection of the Turks, for which it pays a tribute of about 20,000 sequins; though the commerce is beneficial to the Ottomans, in supplying them with ammunition. Jealousy of their neighbours induces the Ragusans to shut the gates of their city, except for a few hours in the day. The capital is Ragusa; and it has been lately annexed, together with Dalmatia, to the kingdom of Italy. It now (1814) probably waits for a new allotment. The Ragusans have many country-houses at Grafova, another sea-port town. Sisagno is another little town, subject to Ragusa. Of the Ragusan isles, the chief is Milet, or Melada, fertile in oranges, lemons, and good wine. On the north there is a tolerable haven, with a town of the same name. Three or four little isles in that neighbourhood also acknowledge the sovereignty of Ragusa.

RAGUSA, the capital of the above-mentioned island, is an ancient city, being the Ragusium of the Romans, and in the tenth century it became the metropolis of Dalmatia. In the 13th century it was conquered by the Venetians, and afterwards for a time subject to the crown of Hungary. It is a well-built city, and its commerce is not inconsiderable. The harbour might be rendered capable of a firm defence; and the circumjacent isles are beautified by nature and art. Earthquakes, however, have been terrible; and that of 1667 destroyed 6000 persons; 245 miles N. of Saloni. N. lat. 42° 58'. E. long. 18° 18'.

Ragusa keeps accounts in ducats of 40 grothetti, each grothetto being divided into 6 foldi; but at the public offices accounts are mostly kept in perperi of 12 grothetti. Formerly the ducat represented a real coin struck at Ragusa, and had a fixed value; but since it has become a money of account, it is always equivalent to the Turkish piaster, and therefore liable to a change of value. At Ragusa no gold coin is struck; its silver are the old talari or dollars, commonly called Villini or Ragusine, weighing 1 oz. 7 car. (Ragusa wt.), containing 17 parts of pure silver to 13 of alloy, and reckoned at 2½ ducat, or 60 grothetti; but on account of the depreciation of the ducat, the value of the tallari has been proportionably raised in weight. The new tallari, called libertine, weighing 1 oz. 10 car. and containing 9 parts of pure silver to 6 of alloy, was valued at 30 grothetti. But since the year 1756, ducats have been coined of 40 grothetti, weighing 3½ an ounce; also perperi of 12 grothetti, weighing 20 carats, and half perperi in proportion to these three coins, contain 14 parts of pure silver, and 11 of alloy. The grothetti, none of which have been lately coined, are still in circulation; they weigh the 60th part of an ounce, and bear the same value with the paras of Constantinople. The ducat of 1796 is worth 13½ florins, which is nearly the value of the Turkish piaster. The tallari, or Ragusina of 1759, is worth than the English standard 4 oz. 2 dwt.; its weight is 18 dwt. 7½ gr., content in pure silver 256.4 gr., and its value in florins 22. 11½ d. That of 1794 is worth 3 oz. 19 dwt.; its weight 18 dwt. 17¼ gr.; its content in pure silver 267.6 gr. and value in florins 31. 1½ d. The ducat of 1797 worth 5 oz. 11 dwt.; its weight 8 dwt. 173 gr., content in pure silver 97 gr., and value in florins 25. 12½ d.

The pound with which gold and silver are weighed at Ragusa consists of 12 ounces; the ounce is divided into 6 faggri; the faggro into 22 carats, and the carat into 4 grains. But the pound of common weight is equal to 567 English grains, or 12 oz. 13d. avoirdupois; the former being 5662 English grains. The ell of Ragusa measures 22½ French lines, or 20½ English inches. Kelly's Un. Camb. RAGWORT, in Botany. See ONTHOXIA, SENCIO, and SOLIDAGO.

RAGWORT, in Agriculture, a very pernicious plant of the weed kind, which is sometimes termed fagrim. It has a green stalk in its early state, but, as it advances in age, inclining to violet or purple, especially downwards. Its flowers are yellow, and thick-set, and composed each of a number of small point leaves. It runs to seed in the latter end of summer. The small, both of the stalk and leaves, which are jagged, as well as the flower itself, are so offensive to animals, as that hardly any will feed upon it, except when almost starved.

It has been proposed to destroy it by picking out the roots, and feeding the land clove with thump. It mostly afflicts meadows and pasture lands when the foils are good.

RAHA, in Geography. See JERicho.

RAHABA, or RABA, town of Arabia Deserta, near the Euphrates, on the road by which caravans travel from Syria to the Arabian Irak; 110 miles S.W. of Moful. N. lat. 35° 5'. E. long. 40° 21'.

RAHABAB Melik Ben Taib, a town of Asiatic Turkey, in the province of Diarbeikir, on the Euphrates; 50 miles S. of Kerkuiieh.

RAHABY, a town of the desert of Syria, containing about five or fix thousand inhabitants, situated on a plain, surrounded with date-trees; 70 miles N. of Megghid Ali.

RAHANPOUR, a town of Bengal; 42 miles N.W. of Natore.

RAHAP, a small island in the East Indian sea, near the E. coast of Bornoe. N. lat. 4° 58'. E. long. 114° 4'.

RAHAS, in Ichthyology, a name given by some authors to the torpedo, or cramp-fish.

RAHEINA, in Geography, a bay on the W. coast of Mowlee, one of the Sandwich islands. N. lat. 20° 50'. E. long. 203° 16'.

RAHEMAT, a large lake in the Arabian Irak, 90 miles in circuit, near Megghid Ali.

RAHENTZAIN, a town of Bohemia, in the circle of Saatz; 19 miles S.W. of Saatz.

RAHMANIE, a town, or rather village, of Egypt, built
RAH

built on the W. bank, at the entrance of the canal of Damankour, which is navigable only at the rife of the Nile; 9 miles S. of Faoa ; which fe.

RAHMETABAD, a town of Peria, in the province of Irak; 20 miles N.E. of Confars.

RAHNIS, or RAXIS, a town of Saxony, in the circle of Neultadt; 10 miles S.W. of Neultadt. N. lat. 50° 33'. E. long. 11° 46'.

RAHNY, a town of Bengal; 25 miles N.W. of Dinagepur.

RAHON, a town of France, in the department of the Jura; 6 miles S. of Dole.

RAHOON, a town of Hindooflan, in the fhah of Lahore; 185 miles S.E. of Lahore. N. lat. 31° 7'. E. long. 75° 42'.

RAH, in Astronomy, is the Hindoo name of the planet of the ascending node, or dragon's head. Ketu is the name of the other node; and a fable, in the usual fyle of mythological allegory, is given under that article, of their origin and milhapat. The malignant Rahu was decapitated, and Ketu was his head. In one painting of the Hindoo zodiac, the headless Rahu is represented of a black colour, in red clothing, mounted on an owl, and holding a fotos in his hand: in another, he holds a fpear, and flands on a tortoise. In the fable given under Ketu it is related that Vishnu was the decapitator of Rahu: other accounts affirm that office to Narayana. Among the Hindoos, as we have had occasion to remark in several articles, their fcience, as well as their history and religion, are enveloped in a mafs of mythological allegory: a farther infance of which, connected with the subject of this article, is feen under Eclipse (Note. A reference being made from the article Ketu to this, we take the opportunity of correcting two typographical errors in that article. In its early part, for Karajafa, read Karajapra; and in the fourth line of the second column, for read a.)

RAHWAY, in Geography. See Rawa.

RAI, or RAI, an ancient town of Peria, in the province of Irak, before Ifpan the capital of Peria. This was once a grand and proud city; and its ruins fill cover a great extent of country. It holds a distinguished place in the annals of Peria: it is mentioned by Arrian and Diocles of Sicilus, as the capital of the province of Rhages, so called from the calamities brought upon this part of the empire by the earthquakes which it formerly was, and is still subject. It is frequently mentioned in the wars of the renowned Haroun al Rashid: it was the capital of this part of Peria, in the reign of Alp-Arslan, and continued to flourish until it was sacked by the generals of Jenghis Khan. Its ruins are situated five miles S. of Tehran, the present capital of Peria; and in the centre of them is a village, called Sheik Abdul Azzeem, from a fon of the ferventh Imam, to whom memory a noble mosque and maufolleum have been ered.

RAJ, denoting king, an appellation given in Hindooflan, or the empire of the Moguls, to princes descended from thofe that ruled there before the conquest of the Moguls; who exercized all rights of sovereignty, only paying a tribute to the Great Mogul, and obferving the treaties by which their ancestors recognized their superiority.

There are some rajmahs who fill retain a more independent sovereignty in the mountains: the Indians call them raj; the Persians, plurally, raja: our travellers rajahs, or rajahs.

These have under their command foldiers, called rajah, or porchons descended from rajahs, who are a robust brave people, and who enter into the service of those who will pay them. The Great Mogul has feveral of these rajahs in his service.

The chief lords of the Moguls, viz. the vice-roys, go vernors of provinces, and chief mulliners of states, who obferves, are called ambra; and the idolatrous rajahs, or Indian lords who governed petty fates before the conquest of their country, held the fame rank at court with the ombras.

All the difference was, that the children of the rajahs succeeded their fathers in the show of the sovereignty left them: whereas the children of the Mahometan lords lose all in losing their fathers.

The Indians account four ages from the beginning of the world: and in the second, which lasted 1,256,000 years, they hold the rajah or kshatrys had their rife: a noble cast, though inferior to the Bramins. Vice then, they say, began to creep into the world: men only lived to 300 years, and their stature was reduced, &c.

RAIA, the Ray, in Ichthyology, a genus of fishes of the order Chondropterigia, of which the generic character is, that it has five oblique spiracles on each side, placed beneath the neck; the head is small, pointed, and not distinct from the body; the mouth is beneath tranverse, toothed; the body is broad, thin, and flat.

The individuals of this genus are all inhabitants of the sea only: they keep at the bottom, and in winter cover themselves with sand and mud: they feed on taffeous animals, fish, or any animal substances which they may happen to meet with. They grow to a large fize, sometimes exceeding 200 lbs. in weight. The females are the larger, and produce their young alive, only one at a time, which, like the shark tribe, are inclosed in a quadrangular, black, horne shell, the corners of which end in slender incurved points, but not extending into long filaments, like thofe of the shark: the eyes are half covered with a thin membrane, oblong, placed on the upper part of the head: above thee, in the place of nostrils, is a broad fucus or groove, divided by a reticulate membrane, confliding of reticled folds, and clofed with a valve: behind this fucus are two small feminal orifices: the tongue is very broad, short, and smooth. The ventral fins are covered with a thick skin, and surrounding the body: the ventral at the base are connected with the anal; the firth is generally ealyable; the liver is large, and producing a great quantity of pure oil.

Of this genus there are nineteen species, divided into three fections: viz. A, comprising the electric ray, or torpedo and fakes; these have sharp teeth. B, including the king-ray and thornsbacks, having obtuse teeth. And C, which are denominated uncertain, comprising five species, which inhabit the Red fea, or about the Cape of Good Hope, but which have not yet been sufficiently examined.

Section A. - With fharl Teeth.

Species.

1. Torpedo; Electric Ray. The body of this fish is entirely smooth and flat. The species inhabits the Mediterranean, and grows to a large fize; some have been taken that have weighed from 60 to 80 lbs. each, but the average weight is less than 20 lbs. It is of a dirty chyf had colour; the head and body are round, and but indistinctly separated. The body is extremely thin; behind the eyes are two wide foramina, which have been supposed to be intended by nature for conveying fount; they are beft with fix cutaneous fingers on their inner circumference, and communicate with the mouth. The torpedo can live about twenty-four hours out of the sea, and a fhort time longer, if put into fresh water.
RAIA.

The species has a smooth belly and back; it has fringes near the eyes, and a triple row of them on the tail. It inhabits the Mediterranean; the body above is marked with an ocellate spot.

* Fullonica; the Fuller Ray. The back is covered with spines; the eyes with a single row; pectoral fins and tail with a triple row. It inhabits the European seas; grows to a large size; the body above is cinnereous, with numerous black spots; beneath it is white. The front of this fish is short and pointed; the mictant membrane is fringed; the teeth are small and sharp; and the tail is slender. It has been thought by some authors that this is only a variety of the next species.

* Rubus; Rough Ray. The back of this species has a single spine; and the tail is beset with a triple row of spines. This is greatly allied to the thornback, but covered with more numerous spines, every part of the skin on the upper surface being mucritated with thorn curved acute of different sizes; of these, one row of the largest runs down the middle of the back, and three, or sometimes five, along the tail; others are dispersed about the eyes and the flaps of the pectoral fins; the general colour is yellowish or white-grey, sometimes variegated with dusky or brownish clouds and thorns; the under side is white, and beset with very numerous fringed spines, but less strong than those on the upper side. It is about the size of a thornback. Mr. Pennant mentions one that measured nearly three feet from the nose to the tip of the tail. It is a native of the Mediterranean and other seas.

B. - Teeth obtuse.

Species.

Sephen. Body nearly round; tail twice as long as the body, winged beneath, and with two long spines above, furrate on each side. It inhabits the Red sea, and is sometimes fo large, as to reach three yards across; body above brown, with three rows of large hemispherical tubercles down the middle of the back; beneath it is quite flat and smooth, and it is of a reddish-white. It is from the skin of this species that the beautiful substance called Golushat is prepared by the French, and which, being coloured with blue, green, or red, according to the fancy of the article, and afterwards polished, is frequently used for various kinds of cases, telescopic tubes, &c. For this purpose the smaller or younger specimens are preferred; the tubercles in the more advanced or full-grown animals being too large.

There is a variety of this species; the length of the specimen described by Dr. Raffel was about 9½ inches; the tail is about two feet nine inches long; the colour of the whole animal is a dull leaden above, with a deep blue tail; beneath it is dusky white; on the middle of the back there are only two pearl-formed tubercles instead of three; the tail is furnished with a sharp spine and a fin beneath. It is a native of the Indian seas.
Aquila. The body is smooth; the tail is pinnate, with a long ferrate spine. This species is of a rhomboidal shape, but with a considerable dilatation; the pectoral fins approach to a subequal form; the colour is emerald above; pale or whitish beneath; the head is rather large, and the snout produced; the eyes are large and prominent, with yellow irides; the tail is long, slender, sharp-pointed, and furnished with the middle with a spine similar to that of the fling-ray. This species grows to a very great size, sometimes measuring ten, twelve, or even fifteen feet in length, and weighing upwards of three hundred pounds. It is found in the Mediterranean, Atlantic, and Indian seas, and is said to swim in a manner than most other rays; it preys on smaller fishes, and is supposed to strike and kill, or at least disable its prey with the caudal spine; when taken, it is observed to vibrate the tail with great strength and rapidity in all directions. It is not reckoned among the edible fishes; but the liver, which is very large, is said sometimes to be eaten, though it is more frequently used for the purpose of preparing it in a clear oil, which it affords in great plenty.

Pastinaca; Sting ray. The body of this species is smooth; its tail has a long sharp spine, ferrate on the fore part, and another on the back; there are two other varieties of which the one has a smooth body; the back is beft with two spines, ferrate on the fore part; the body of the other is covered with spots.

This species is described as having a body somewhat approaching to the ovate, the pectoral fins long pointed, and in some other species of this division. The snout is pointed; the body more convex than usual; the colour of the whole animal above of a yellowish-olive, but the back is sometimes found to approach to a blueish-brown; beneath it is whitish; the tail is of a considerable length, and without a fin, very thick at the base, and gradually tapering to the extremity, which is very slender; near the middle it is armed, on the upper part, with a very long, flattened, and sharp-pointed bone or spine, finely ferrate in a reversed direction on both sides; with this the animal is capable of inflicting very severe wounds on such as inadvertently attempt to handle it; and it answers the purpose both of an offensive and defensive weapon. This weapon is annually cast, and as it frequently happens that the new spine has arrived at a considerable size before the old one has been cast, the animal is occasionally found with two, in which case it has been sometimes erroneously considered as a distinct species. This fish is said not to grow to a very large size. It is found in the Mediterranean, Atlantic, and Indian seas, and is numbered among the edible rays. On account of the danger attending the wounds inflicted by the spine, it is usual with the fishermen to cut off the tail as soon as the fish is taken. In some countries it is said to be illegal to fell the fish with the tail adhering to it.

It was formerly thought that the spine of the fish possessed a venomous quality, by infusing into a wound made by it some very active poison; this is now proved to be completely erroneous, and the effects sometimes produced by it arise entirely from the deepness of the puncture and laceration, which, if taking place in a tender or a part, or among the larger nerves and blood-vessels, have often proved fatal. It may not be amiss to observe, that some ancient writers have deceptions upon the effects of this animal's powerful weapon in terms of considerable luminance; it was supposed to be not only poisonous to the living animal, but to preserve its poison when taken from the fish, and affixed to the head of an arrow or a spear; it was said even to destroy the most healthy and nourishing plant by its touch, and even to cause trees to die by striking the bark with its point. It formed the head of the fatal spear presented by Circe to her son Telemon, by which she was rendered superior to his enemies, and with which she, at length, unconfessingly, flew his hero Ulysses. The general habits of this species are similar to those of the rest of the genus, often lying flat, and in ambush on the soft mud at the bottom of the flares which it frequents, and feising its prey by furprize; at other times it will pursue it through the depths of the ocean.

*Clavata; Thornback. The body of this species is spinous; the teeth tuberculate; across the belly is a strong femur cartilage. This species grows to a very considerable size, though rarely equal in magnitude to the skate already described; in its general appearance it resembles that fish, but is somewhat broader in proportion, and is readily distinguished from the skate by the very strong, curved spines with which its upper surface is covered; these are most conspicuous down the middle and on each side of the back, where four or five, of much larger size than the rest, are generally seen; the remaining parts being furnished with many smaller spines of a smaller size, intermixed with other minute ones, and the whole skin is of a rough, or thigreen, like surface; the back is marked with an uncertain number of pale or whitish round spots of different sizes, and which are commonly surrounded with a blackish or dark coloured edge; these spots are said to be caused by the shedding of the spines at different intervals; along the middle of the back runs a single row of strong spines, continued to the tip of the tail; the colour of the skin is a brownish-grey, with irregular blackish or dusky variegations; the under part is white, with a light cast of flesh-colour, and about the middle of the body, as well as on the fins, are disposed several spines similar to those on the upper side, but less strong. The thornback is an inhabitant of the Mediterranean and other seas, and is held in some esteem as food, though not considered equal to the skate in goodness.

Rhinobatos. Body long, tapering; snout lengthened. This is reckoned a very remarkable species, and is thought to connect in some degree the genera of raia and squama, the body being much longer than in the preceding kinds of rays; the snout is lengthened, but not very sharp; and the body, which is moderately convex above, and flat beneath, gradually tapers from the shoulder to the tail, which is furnished above with two fins, of an oblong shape, and situated at a considerable distance from each other: the tip of the tail is also dilated into an oblong fin. The colour of the whole fish is of a dull earthy brown, paler beneath, and the skin is every where roughened by minute tubercles. This fish is said to grow to the length of about four feet, and is a native of the European seas. It is very frequently seen about the coasts of Naples.

Dipndenus. Tail-fin two-lobed; spines in a triple row at the beginning of the back, and afterwards in a single row; the first dorsal fin is above the ventral. It inhabits the Red sea, and is about two yards long. The body is a little rough, and of a pale ash colour; above it is varied with whitish spots; beneath it is whitish; behind the vent are a few brown and white liripes.

Lamna. Body oval, smooth, tesselaceous, with blue spots; pinnate tail with a single spine. It inhabits the Red sea. It is hardly a foot long; the spots oval, unequal, beneath whitish. It is much allied to the eagle-ray, and is of a reddish-brown colour above; the tail is somewhat longer than the body, marked above, for half its length, with two longitudinal blue liripes, and is furnished about the middle with one, and sometimes with two, large and ferrate spines, which
which are covered at their base by a blueish-brown skin; the under part of the body is pale or whitish.

**Arran.** Body orbicular, silvery; tail round, without a fin, and furnished with two spines. It inhabits the Red sea; the teeth are granulate.

**C. Uncertain.**

**Omnisesschert.** Tail round and spotted. It inhabits the Red sea, and very much resembles the R. palfinaca.

**Tajara.** Tail round; body beneath snowly. It inhabits the Red sea. When just taken, it beats violently with its fins.

**Schoukie.** Body with a few remote spines. It inhabits the Red sea. The Africans make scabbarbs for their swords out of its skin.

**Mula.** Beneath snowly; tail round, variegated. It inhabits the Red sea, and approaches the shores by night. The spine on its tail inflict a dangerous wound.

**Rapensis.** Back with a single fin; the tail is short, pinnate at the end; the body is smooth and unarmed; and the finot is a little obute. It inhabits the Cape of Good Hope, is shaped somewhat like the torpedo, except that it has a fin on the back. The body is small and orbicular; above it is convex, beneath flat.

**RAJABARRY, in Geography**, a town of Bengal; 10 miles S. of Dacca. N. lat. 23° 24'. E. long. 96° 36'.

**RAJACOTTY, in Thibet; 60 miles N.W. of Sirinagur.**

**RAJAGUNGE, a town of Asfam; 16 miles S. of Gentiah.**

**RAJAGUR, a town of Hindoostan, in Bahar; 35 miles W.S.W. of Gayah.—Alfo, a town of Hindoostan, in Guzerat; 10 miles N.E. of Champaneer.**

**RAJAHUN, a town of Hindooftan, in the circcr of Ciccacole; 12 miles W. of Ciccacole.**

**RAJAKERA, a town of Hindooftan, in the province of Agra.**

**RAJAMUNDRY, a circcr of Hindooftan, bounded on the N. by the circcr of Ciccacole and Golconda, on the E. by the bay of Bengal, on the S. by the circcr of Ellore, and on the W. by Golconda. It is croffed by the Bain Gonga from N. to S.—Alfo, the capital of the above-mentioned circcr, situated between Ellore and Ciccacole, on the Godavery. Its principal riches confift of forccf of teck-wood. N. lat. 17°. E. long. 81° 57'.

**RAJANAGUR, a town of Bengal; 25 miles S. of Dacca.—Alfo, a town of Hindooftan, in the circcr of Rajamundry; 7 miles N.E. of Rajamundry.**

**RAIANA, in Botany, fo called in honour of our im- mortal naturalift, the Rev. John Ray, the moft accurate in obervation, the moft philosophical in contemplation, and the moft faithful in description, amongst all the botanifts of his own, or perhaps any other, time.** His life will be given hereafter, in its proper place. Plumer, who established this genus, finding the name Raia preoccupied by zoolo- gists, contrived to call the plant Jan-Raia; which Linnaeus turned about into Rajania, still retaining the idea of the Chriftian name combined with the other. But such an idea is ludicrous to English ears, and is happily not, in general, perceived. We pretermite to alter the orthography in one letter, writing the word as it is always pronounced, and deducing it regularly from the Latin Raia, by which name the perfon commemorated is known all over the literary world.—Plum. Gen. 33. t. 29. Linn. Gen. 525. Schreb. 692. Willd. Sp. Pl. v. 4. 788. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 391. Juff. 43. Larmorck Illust. t. 818. Gärtn. t. 14.—Clas and order, Dioecia Hexandria. Nat. Ord. Sarmentacea, Linn. Alpa- ragi, Jaff.

**Gen. Ch. Male, Cal. Perianth bell-shaped, in fix deep, oblong, pointed segments, moss spreading in their upper part. Cor. none. Stem. Filaments fix, brachte-shaped, shorter than the calyx; anthers simple.**

Female, Cal. Perianth superiour, of one leaf, bell-shaped, in fix deep segments, permanent, withering. Cor. none. Petil. Germen inferior, compressed, with a prominent border at one side, three-celled; style three, the length of the calyx; stigmas obtuse. Peric. Capsule membraneous, of three cells, without valves, crowned by the calyx; two of the cells barren, almost obliterated, without wings; the third fertile, compressed, extended into a very large, half-ovate, membraneous wing. Seed solitary, nearly elliptical, compressed.

**Section 1. Leaves simple.**

1. **R. balfata.** Halberd-leafed Raiania. Linn. Sp. Pl. 1461. (Jan-Raia scandelens, folio oblongo, angusto et auricolatu; Plum. Gen. 33. Bryonia fructu alato, folis auriculatis; Plum. Amer. 84. t. 98.)—Leaves halfate; somewhat heart-shaped at the base.—Gathered by Plumer, about Port-de-paix in the island of Hispaniola. Root perennial, sometimes large and ovate; sometimes four or five inches long, and two thick, round at each end, like a clafse. Its subfinnate resembles that of a rhinophy, without any internal fibres; the bark thin, firm-coloured, a little rugged and warty; the flesh very white, taffing like a bean. This root throws up only one very slender, long, climbing, smooth, knotty stem, thickf at the base, where it is accompanied by several fibrous radicles. We prefigure it to be annual. Leaves scattered, spreading, on short flials, smooth and membraneous, about three inches long; heart-shaped, dilated, abrupt, and vein-ribbed at the base; then suddenly elongated into a nearly linear, entire, central, three-ribbed lobe, bluntp, with a small point; the under fide paler, and rather downy. Stapules in pairs, awl-shaped, minute. Flowers small, whitifh, in simple, axillary, drooping clusters. Bractes minute, ovate, acute, solitary at the base of each partial fliak. Fruit, as Plumer fays, like half that of a maple-tree, of a filvery hue when young, but afterwards tawny.

2. **R. cardota.** Heart-leaved Raiania. Linn. Sp. Pl. 1461. Ait. n. 1. (Jan-Raia cardens, folia tamni; Plum. Ice. 148. t. 155. f. 1.)—Leaves ovate; somewhat heart-shaped at the base; seven-ribbed.—Native of the West Indies, from whence it was sent to Kew garden, in 1786, by Mr. Alexander Anderson. It flowers in the flore in July, and we cannot but think some accurate botanift would produce a good figure and description of the plant, out of respect to its name. Plumer repreffes the habit of this root, stem, &c. much like the foregoing; but the leaves are regularly ovate, pointed, more or less heart-shaped at their base, and furnifhed with few ribs continued from that part to the point. These ribs are connected by numerous trans-verse veins. Inflorescence, flowers, and fruit, much as in R. balfata, but having few seen their species, we can fay nothing respecting the stipules or bractes, none of which are noticed in the plate.

fused, with slender, smooth, leafy branches. Leaves rather dill, flaked, smooth on both sides, pointed, entire, three-ribbed, veiny; ovate at the base. Flowerstalks round, smooth, often as long as the leaves. Clusters axillary, numerous, longer than the leaves, slender, many-flowered, rather zigzag. Flowers diptocarpous; the male in compound clusters, females in simple ones, all flaked, and turned toward one side. Corella very minute, yellowish-green in the male, reddish in the female blossoms. Cappule comphosed, with an ovate, falcate, membranous wing.

4. *R. angustifolia.* Narrow-leaved Raintania. Swartz Ind. Occ. v. 1. 639. Mart. n. 3.—"Leaves linear-lanceolate; rounded at the base, three-ribbed. Native of extremely dry bulby places, in the west part of Hiffapanola, where it climbs upon high trees, flowering in May. Root annual. Stem thread-shaped, round, twining, flaccid, sub-divided, smooth. Leaves nearly a span long, entire, three-ribbed, veiny, smooth. Flowerstalks smooth, red, twined according to the direction of the stem. Clusters axillary, in pairs, the length of the leaves, pendulous, slender, many-flowered; the flowers very minute, nearly sessile, red, polygonal, five or six on each of the alternate smaller stalks, all leaning one way. Bracteæ very minute, acute, blood-red, under the flowers. On some plants the latter are entirely male, with five or six sessile anthers; on others all hermaphrodite, with six perfect flowers, a triangular oblique gemma, no style, but three minute stigmas. Cappule as in the root of the species. Swartz.

5. *R. quinquefolia.* Five-leaved Clustered Raintania. Linn. Sp. Pl. 1462. (Jan-Rain) scandens quinquefolia; Plum. It. 149. t. 155. f. 2.—Leaves five together at each joint, elliptic-oblong. Clusters lateral, between the joints. Native of the Weil Indies, but hitherto observed by Plumber only. This seems to have the habit of all the foregoing, except that the stem is tumbid joints, at each of which stand five elliptic-oblong, obtuse, entire, three-ribbed leaves, about three inches long, on short flowerstalks. The clusters are represented not axillary, as in the others, but lateral and alternate, from the spokes of the stem between the joints.

Section 2. Leaves compound.

6. *R. quinata.* Five-leaved Umbellate Raintania. Thumb. Jap. 148. Mart. n. 6.—Leaves five on a common stalk, emarginate. Umbels axillary. Observed by Thunberg about Nagasaki and in Kofu, in Japan, flowering in April and May. The Japanese call this plant Fagi Kafura, and Akis. Stem twining, round, smooth, dull-coloured, branched. Leaves several together, axillary, flaked, smooth, offive separated flaked, umbellate, ovate, entire leaflets, each from three-quarters of an inch to an inch and a half long, emarginate with a point. Common flowerstalks thread-shaped, smooth, two inches or more in length; partial half as long as the finger nail. Flowers in umbels, from the same buds as the leaves, on slender stalks as long as the flowerstalks; partial stalks capillary, the length of the niall. This species differs from the last in having compound leaves, and umbellate flowers. Thumb.

7. *R. luteaeflora.* Six-leaved Clustered Raintania. Thumb. Jap. 149. Mart. n. 7.—Leaves six on a common stalk, oblong, acute. Flowers racemose. Native of the country of Pakonka, in Japan, among bulks, flowering in April. Its vernacular names are Akis, Mke Kafura, and Tju So. The stem is round, fluted, smooth, climbing. Leaves alternate, smooth, six on a stalk, umbellate, on slender partial stalks, oblong, acute, entire, two inches long; pale at the back. Common flowerstalks round, bent, three or four inches long, swelling at each extremity. Flowers in axillary clusters, snow-white. Differs from *R. quinata* in having mostly six leaflets on a stalk, which are acute, reticulated with veins at the back, and larger than in that species. The flowers moreover grow in clusters, not umbels.
a town of Hindooftan; 20 miles E.S.E. of Allahabad. N. lat. 24° 40'. E. long. 80° 17'.

RAJEGUSDAR, a town of Hindooftan, in Lahore; 35 miles E.N.E. of Behnur.

RAJEHANUT, a town of Bengal; 16 miles N.W. of Bifonpur. N. lat. 23° 1'. E. long. 86° 40'.

RAJEMAL, a circur of Bengal, bounded on the N. by Purneal, on the E. by Purneal, Maulde, Dinagepur, and Raajeevli, on the S. by Sultanabad, and on the W. by Hindoos and Bagdopur. — Also, the capital of the above circur, lying on the W. bank of the Ganges, nearly in the parallel of Maulde, and about 20 miles from it; at the foot of the chain of hills which projects into the river at Sielgally and Terraigally. It is in a ruinous state, although not above 14 centuries ago the residence of the viceroy; and has hardly the population of an ordinary market-town at present. Its situation is romantic, but not pleasant; for in Hindooftan, the hills and enmeuses being always covered with wood, that beautiful swelling of the ground, which is so juftly admired in European landscapes, is lost; and the fancy is presented at first with nothing beyond a wild scene; which can only be relicted by being contrasted with soft and beautiful ones. It is more than thirty miles above the head of the delta of the Ganges, and therefore M. d'Anville placed it erroneously by aligning its situation at this place. N. lat. 25° 27'. E. long. 87° 56'.

RAJEMATCHY, a town of Hindooftan, in Vifapour; 37 miles N.W. of Poonah.

RAJEMUNGLAM, a town of Hindooftan; 16 miles S. of Tinvelly.

RAJETEA, one of the South-sea islands, named also Utteca; which feecn.

RAJETPOUR, a town of Bengal; 15 miles S. of Rogonapour.

RAJEWICE, a town of Lithuania; 42 miles S.S.E. of Braels.

RAIGIR, a town of Hindooftan, in Golconda; 10 miles S.E. of Beder.

RAIGUR, a town of Hindooftan, in the circur of Sumbulpour; 15 miles N. of Sumbulpour.

RAIK, a town of Syria, on the Euphrates; 18 miles S. of Bembig.

RAIL, in Arlhitecture, is applied variously; particularly to those pieces of timber which lie horizontally between the pannels of window, and over and under them.

The word is also applied to those pieces of timber which lie over and under baliffiers in balconies, ittaricafe, &c.

Also, to the pieces of timber that lie horizontally from poff to poff in fences, with pales or without. See Fence.

RAILS, in a Ship, are long narrow pieces of fir, or oak, with mouldings of regular members of architecture struck on them, which are fulten, or fometimes wrought from the folid plank, as ornaments to the ship's fides. The former are now conflruated in the navy, as they were found to rot the fides very much; the latter, wrought from the folid plank, are ufed in merchant ships. The rails of the head and ftern are pieces of oak timber handfoinely wrought with mouldings. The lower rail along the fide is named the waif-fail, and the next above it the quarter-fail, which are generally placed parallel to the top timber line, the quarter-rail with the top of the fide amipiffs, and the waif-rail about twenty inches below it; the rails next above and parallel to the quarter-rail are called drift-rails, and the rails above the plank-fail, if any, the fife-rail. The rails of the head are diftinguifhed by the upper or main-fail, the middle and the lower-fail; and the rails of the ftern take their names from the parts to which they are fixed, as the back-rail, lower
counter-rail, upper counter-rail, foot space-rail, beaff-rail, raffel-rail, and confel-rail. (See Plate 1. Ship-building.) To these may be added the thwafthip pieces of the framing of the great cabin bulk-heads.

Rails of the head are certain curved pieces of timber, extending from the bows on each side to the continuation of the ship's item, to support the knee of the head, and the ornamental figure fixed upon it.

RAIL or Water-Rail, in Ornithology, the name of the rallus aquaticus of authors, which is a bird of a long fender body, with short concafe wings. The bill is fender, slightly incurvated, and one inch three quarters long; the upper mandible black, edged with red, the lower orange-coloured; the rudes red; the head, hind-part of the neck, the back and the wings and tail are black, edged with orange-brown; the face of the wing is white; the quills feathers and fecondaries duny; the throat, breast, and upper part of the belly, are ah-coloured; the fides under the wings, as far as the rump, finely varied with black and white bars; the tail is very short, consisting of twelve black feathers; the ends of the two middle tips with rail colour; the feet immediately beneath the tail white; the legs are placed far behind, and are of a doubtful colour; the toes very long, and divided to their origin; though the feet are not webbed, it takes the water, will swim on it with much cafe, but is often observed to run along the surface. It delights to fly high in running, which it does with extreme along the edges of brooks covered with rushes. When it runs, it every now and then flirts its tail, and in flying hangs down its legs. Pennant.

This bird, says Mr. Pennant, is properly fui generalis, agreeing with no other, but forming a separate tribe; though M. Brotteau and Linnaeus place it with the land-rail, and Mr. Ray with the water-hens. It is a well-tailed bird.

RAIL, Land, the rallus creb of Linnaeus, is a migrating bird, with a short, strong, thick bill; always found among corn, grass, broom, or furze. It leaves this kingdom before winter. They have long legs, and a fingular note, resembling the word creb, often repeated. The feathers on the crown of the head, hind part of the neck, and the back, are black edged with bay colour; the coverts of the wings of the fame colour, but not spotted; the tail is short and of a deep bay, the belly white, and the legs ah-coloured. They are in great fplendid in Anglefia, where they appear about the 20th of April, supposed to pass over from Ireland, where they abound. They are found in mof of the Hebrides, and the Orkneys. Pennant.

RAILING, in Rural Economy, a fort of fence con-}
as subjects of railery. It is below the character of persons of humanity and good breeding, to indulge mirth, while any one in the company is suffering, as the effect of that mirth, pain and mortification.

RAILWAY, tram or Drum-road, or Waggon-ways, in Rural Economy, a track constructed of iron, stone, timber, or other material, upon the level surface of an inclined plane, or other situation, for the purpose of diminishing friction, and thus serving for the easy conveyance of heavy loads of any kind of articles. See Plate IV. Canals, figs. 31 to 35.

It has been remarked, that railways have hitherto been confined, almost exclusively, to coal-works, and other mines; and that inventions, whole only recommendations are implicitly and usefully, are often suffered to lie long in a state of public neglect; while others, perhaps, of no real utility, but of more imposing aspect, and being pertinently blazoned forth by interested or blinded partizans, are readily adopted; and bask, for a while, in the furnshine of public favour. The time has, however, at length arrived, when carriages moving on level surfaces, or on gently inclining planes, with little friction, and without obstructions, are fast spreading over the face of the country. It has been observed that there may be many line-works, as well as other forts, from which railways may be laid, in different directions, with great benefit to their proprietors and the surrounding neighbourhoods in general.

With the view of diminishing horse labour, it has been suggested by Dr. Anderson, in his Recreations in Agriculture, that where internal canals cannot be established, this may be effected, and intercourse facilitated, by means of railways, which have not yet been introduced into general practice. It is further stated, that they were first solely employed for transporting coals to a moderate distance from the pits, to the places where they could be shipped, being universally made of wood. And long, says he, had they been applied to this use, without any idea having been entertained that they could be employed for more general purposes. By degrees they were, however, carried to a farther extent; the scarcity of wood, and the expense of their repairs, suggested the idea of employing iron for the purpose of improving these roads. At the first, flat rods of bar-iron were nailed upon the original wooden rails, or as they were technically called, fleperis; and this, though an expensive process, was found to be a great improvement. But the wood on which these rested being liable to rot and give way, some imperfect attempts were made to make them of cast iron, but these were found to be liable to many objections, until the buffers was taken in hand by Mr. Outram, engineer, at Butterfly Hall, Derbyshire, who contrived at the same time, so far to diminish the expense, and improve the strength of the road, as to bring them to a degree of perfection, that no one who has not seen them can easily conceive could have been done. And it is added, that this having been carried into execution in a few cafes, and found to answer, has been improved upon and simplified by practice, till it is now brought to such a state of perfection as to have given proofs, that it admits of being carried much beyond the limits of what was for many years conceived to be possible, and to afford demonstrative evidence, that it may be in future employed to a wider extent still, to which no limits can be at present assigned or foreseen.

There are a great number of railways in Derbyshire, Shropshire, Lancashire, and many other parts of the country.

In the first of the above counties, there are railways of very different lengths; one of five miles in length, leading from the town of Derby to the collieries in the vicinity; another, from the lime-estone rocks on the Cranford canal, called the Creick railway, which is about one mile and a half in length; a third from the Beggarslee colliery to the same canal, denominated Barber and Walker's railway, of similar length; a fourth from the lime-works in the neighbourhood of Bolton, to the canal near Whaley bridge, termed the Peak-forell railway, which is about six miles in length; a fifth called the Marple railway, of about one mile and a half long, on the Peak-forell canal; sixthly, railways over Bifworth-hill near Nottingham, on the Grand Junction canal, which are three miles and a half in length, and constructed in a double manner; a seventh, which has the name of the Abby de la Zouch railway, has four miles of double and eight miles of single rails. Some of these railways are formed in a very complete manner, especially those which have been made since the various improvements of them were introduced. They have been of prodigious utility and advantage to the county, both in regard to its agricultural improvements and its manufacturing interests and concerns.

These forts of railway roads have likewise been introduced into many parts of the county of Salop, with vast benefit and success to the different interests of the districts. They have here had a new application, in being employed for the purpose of conveying heavy weights from different levels on canals.

Speaking of the great utility of canals in the carriage of various articles in this county, it is observed by Mr. Telford, an able engineer, that another mode of conveyance has frequently been adopted to a considerable extent; which is that of forming roads by means of iron rails laid along them, upon which materials are carried in waggons, which contain from six to thirty hundred weight; experience, he thinks, has now convinced us, that in countries the surfaces of which are rugged, or where it is difficult to obtain water for lockage, where the weight of the articles of the produce is great in comparison with their bulk, and where they are mostly to be conveyed from a higher to a lower level, that in those cafes, iron railways are in general preferable to canal navigation.

It is supposed, that on a railway well constructed, and laid with a declivity of fifty-five feet in a mile, one horse will readily take down waggons containing from twelve to fifteen tons, and bring back the same waggons with four tons in them. This declivity, therefore, suits well, when the imports are only one-fourth part of what is to be expected. If the empty waggons only are to be brought back, the declivity may be made greater; or an additional horse applied on the returning journey will balance the increase of declivity. If the length of the railway were to be considered, it may, it is supposed, without much inconvenience, be varied from being level to a declivity of one inch in a yard, and by dividing the whole distance into separate flages, and providing the number of horses suitable for each portion of railway, according to the distance and degree of declivity, the whole operation may be carried on with regularity and dispatch.

It is upon the whole believed, that this useful contrivance may be varied so as to suit the surface of many difficult countries, at a comparatively moderate expense. It may be constructed in a much more expeditious manner than navigable canals; it may be introduced into many districts where canals are wholly inapplicable; and in case of any change in the working of mines, pits, or manufactories, the rails may be taken up and laid down again in new situations, at no very great expense or trouble.

It is also further noticed, that some parts of this and the neighbouring counties, in which canals had once been intended
intended to be formed, have since been looked over and examined with the view of having iron railways instead of navigable cuts; and in many cases this may be the most advisable and proper, particularly in all situations where difficulties arise in the constructing of navigable canals, or other sorts of works for water carriage.

The county of Lancashire, too, has a great many of these iron railways for the convenience, accommodation, and advantage of the different collieries, manufactories, and other works, where heavy loads are to be transported. The coal work near St. Helens, in the vicinity of Liverpool, has a double railway some miles in length; and at the iron-works of lord Belcarra, near Wigan, as well as his canal coal pits near the same place, there are double railways of very considerable length. To the south of the town of Preston, at a small distance from Bamber bridge, there is likewise one communicating with the Lancaster and Kendal canal, which is also double and of great length; serving to convey the coals from the southern parts of the county to that canal, in order to their distribution in the northern parts, and the adjoining districts.

On the east side of the same county they also prevail in many places, and are found of the greatest use, being the means of dispatching much business in a ready manner and without much expense of labour.

The utility of these railways has been found to be extremely great in other coal-works and canals, where they are at present very extensively employed; and it has been suggested, that they may be applicable in other cases, as for shortening the team labour of a farm so as to bring it within one day's journey, where more than one were formerly necessary, by which a great saving in labour and expense may be made. Also, in rendering the business of lime works more easy and expeditious in different instances. It has likewise been hinted by Mr. Bentfon, in the first volume of Communications to the Board of Agriculture, that they might be had recourse to on roads where there are unavoidable riles or falls, for taking up or letting down heavy loaded wagons or other carriages. It is observed, that near Colebrook Dale there is one at a small distance from the iron bridge, upon which loaded boats are drawn up to a canal, two hundred and twenty feet above the level of the river Severn, and let down in a similar manner into it, by which means twenty-two locks are faved, and the work executed in an expeditious manner. It is suppos'd, that this is the greatest inclined plane in Europe, or perhaps in the world, for though they are much used in China in the place of locks, he has never heard of any of them being equal in height to this. The rails are bell made of iron. It is added, that they have been found useful in improving soft, moffy, boggy lands, on which horses cannot travel; a rail road of this sort having been formed through a peat moss near Manchester by Mr. Wakefield, while it was under improvement, at the expense only of about three hundred pounds a mile, on which a single horse was capable of drawing with the greatest facility seven wagons at once, each being loaded with about seven hundred weight of marle, bearing in the whole forty-nine hundred weight, and with the weight of the wagons upwards of three tons. This was performed, it is observed, over a place where a few months before a dog could hardly venture without the danger of being famped. On the Ketley and other canals in the county of Shropshire, vast advantages have been derived from laying railways upon inclined planes, and letting down and drawing up the different articles by means of machinery, as may be seen in the very able Agricultural Report of that district, where excellent representations of them are given.

Besides these different cases of railways, another has been suggested by the writer of the Annals of Agriculture, which is that of having them laid from the back-yards to the threshing machines, by which the grain may be conveyed to them at any time with ease and convenience, as well as any particular hitch that may be wanted.

It is further stated by the ingenious Dr. Anderson, that the best idea he can give of the benefit that may result to the community from the use of this kind of railways, will be from stating some facts respecting them, which were lately communicated to the Society of Arts by Mr. Wilkes, of Meafham, near Loughborough, in Leicestershire; a spirited and judicious agriculturist. He had a railway of this sort made, which was about five miles in extent, leading from a coal-mine to a market. He found it to fully answer his expectations after it was finished, that he communicated to the above society an account of some trials he had made of it, requesting that such of the members of that respectable institution as were desirous of information on that head, would do him the honour to witness some experiments that he wished to make upon it, for the information of the public. A committee of the members was accordingly deputed for that purpose, and before them he shewed that a moderate sized horse, of about twenty pounds value, could draw upon it with ease down hill (the descent being one foot in a hundred) thirty-two tons, and without much difficulty forty-three, and seven tons up hill, independent of the carriages. The doctor concludes from these facts, that upon a perfect level a horse could draw with ease from ten to twenty tons. It is observed, that Mr. Wilkes's railway, on which the experiments were made, was, from local circumstances, laid upon wooden sleepers, and is not so perfect as those done upon stone. But it is added, that twenty tons are the load which such a horse could draw with ease, travelling at the usual waggon rate, in boats upon a canal; so that the number of horses required in this way will not be much, if at all, greater than on a canal. Certain advantages attach to this mode of conveyance, which do not so well apply to a canal, and vice versa; but it is not his intention to draw a parallel between these two modes of conveyance. Nobody can entertain any doubt, he thinks, about the utility of canals where they are easily practicable. He only wishes to point out this as an eligible mode of conveyance, where canals cannot be conveniently adopted.

It is further remarked, that it was customary at the first, to put the whole load to be drawn by one horse upon railways into one waggon; but now, when the load is so much augmented, it has been found eligible to divide it into many parts, so that no one waggon shall carry more than one or two tons; by this method the weight is so divided, that the prelude is never so great upon one point as to be in danger of too much crushing the road; the carriages can be made much more limber and light in all their parts, and they are much more easily moved, and more manageable in all respects than they otherwise would have been. And another advantage of this arrangement, which deferves to be particularly adverted to, is, that it admits of shifting the carriages so as to leave a load, as it were, in parcels at different places where they may be required, without trouble or expense. This, when it comes to be fully understood and carried into practice, will, he thinks, be a convenience of inestimable value, a thing that has been always wanted, and never yet has been found though it has been diligently sought for. The able writer has here endeavoured to illustrate its importance and utility in transporting goods from the wet docks now forming on the Isle of Dogs to London, and in carrying roads to distant different parts of the country; in which cafes,
RAILWAY.

eafes, and in all where there is much business to be done, they would require to be double, one for going, and the other for coming upon, to prevent interruption and interference.

And he afterwards offers a few remarks, tending to show the practicability of the measure, and to guard against setting out upon a bad plan, which might, if supposes, in time to come, frustrate the good that might have resulted from the undertaking; merely promising, that he proposes these railways solely for the purpose of conveying weighty loads, leaving the roads, as at present, open for coaches and light carriages.

Also with a view to discover how far it may be practicable to introduce these iron railways into general use, he has made some inquiries respecting the expense of making them; and although this must vary according to the abundance and goodness of materials, and other circumstances, the following statement may serve to give some general notions on that head. In the most eligible situation, where materials are abundant and good, and circumstances favourable, the lowest expense at which a single railway of this kind can be made, will be about one thousand pounds a mile. But at a single railway must be liable to great inconveniences, unless under very particular circumstances, double railways ought to be considered as the only useful fort. These, for public purposes, according to the opinion of the inventor, should be very substantially made. The metal used should be of the flooted fort, and of substance enough, not merely to carry the weights proposed, but to be equal to bear almost any blow or shock, that they may be likely to experience; and, thus made, what they will lose by rust or wear, will be long ere it materially weaken them. Made after such a manner, in favourable situations in the country, a double railway may be thinks, colt about two thousand pounds a mile, but in the neighbourhood of London, where the charge of every thing is high, and where they should be of the strongest fort, we should suppose they might cost nearly three thousand pounds a mile. It is bad economy, he thinks, to fave on articles of this fort at the first; for the little expense thus laid out then will have much in repairs: how small these repairs are, may be imagined from this circumstance, that when a road is thus made, the undertaker does not scruple to supply all that are broken, free of charge, for the first three years. Say then that such a road cost three thousand pounds a mile, this would bring a charge upon the turnpike of 50cl. a-year; say 30cl. more for annual repairs; this is, in all, 200cl. per annum. Compare this with the expense of keeping the present roads in repair. It has been suggested to him, that there is annually laid out in repairs upon the road from Hyde Park Corner to Hounslow, considerably above one thousand pounds a mile; so that the difference of expense is, even at the beginning, very much in favour of railways: and were the money thus at first expended to be gradually paid off, the tolls might thus be lowered almost to nothing. And, he thinks, that a turnpike road cannot be made in almost any situation for less, as he is told, than 100cl. per mile; but where it is of considerable width, as near great towns, it will run from 150cl. to 200cl. per mile; and in annual repairs, including the purchase price of materials, carting them on the road, spreading, raking off, and carting away again, from 100cl. to 100cl. a mile. Say 150cl. prime cost, the interest is 15cl. and 15cl. for repairs, the annual charge of such road will be 225cl.

This is an expense of 10cl. 3 years more than the other. But for the present, let us suppose that this will be equal, the extra charge for purchasing ground for a new waggonway, &c. being equal to that surplus; let us now see what would be the difference of charge to the employers of these wagons in the two cases. Supposing the road to be so much employed as that 100 wagons (or loaded carriages to the same amount) pays each day, carrying fix tons each, drawn by eight horses; these, at one shilling each wagon for toll (for two-pence a ton), would produce 3l. a day, or 1825cl. a-year; which, at the rate of eight miles for each turnpike, would be 225cl. per mile, the surplus being produced by road horses and light carriages. The charge then to the employer, for this flag, must be 1825cl. and the keep of 800 horses, besides servants, incidental charges, and owner's profits for the transporting of 600 tons of goods a day. Say that the same horses travel two stages a day, the turnpike money would be doubled; that is, 365cl. per annum; the keep of 800 horses, at 2s. each per diem, is 29,200cl. These sums added make 38,550cl.; owner's profit and incidental charges, say 10 per cent., 3,285cl.; in all 36,135cl., or, on 219,000 tons (being 600 tons a day), about one-fourth per ton. And supposing the fame quantity of goods carried on the railway, and the same turnpike money paid, and that each horse drew only fifteen tons, this would require only, he thinks, forty horses; the keep of which, at 2s. a day, would be 146cl., add the toll, 1825cl. is 3285cl. Owner's profit, &c. upon this sum 10 per cent. at above, 328cl.; in all 3613cl., or about four-pence a ton, just one-twelfth part of the charge in the other case. He thinks, that when the object comes to be considered in this point of view, few measures that can be proposed will hold forth such an important national improvement as this would be. Considered with regard to the consumption of the produce of the earth (an object at present deferring the fulfilment, and improvement is applied to almost every part of the country), it would, he supposes, reduce the number of heavy road horses to one-eighth part of what they are at present, and of course augment the number of cattle or other consumable provisions in a proportionate degree, so as greatly to lower the price of the necessaries of life. It would, in the next place, lower the price of the carriage of goods of all kinds to an amazing extent; and lastly, as a consequence of that, it would give such encouragement to agriculture, as no other measure that can be contrived could ever effect, and that without causing one shilling expense to any one individual, or to the state. On the contrary, by inducing cheapness of provision, and affording such efficacious encouragement to manufacturers and to agriculture, it would produce a general prosperity, which, by augmenting the consumption of taxable commodities, would augment the public revenue; while, at the same time, every individual would feel himself relieved from the preliure of many taxes that prove disagreeable to him at present. After justly repudiating every sort of gambling speculations by mean men in undertakings of this nature, and shewing the numerous evils that attend them, he advises it, as highly necessary to prevent these railways from ever becoming private property, on any account, to keep them open and patent alike, to all who shall choose to employ them as a king's highway, under such regulations as it shall be found necessary to subject them to by law. In short, they should, he thinks, be put upon the same footing, in all respects, as public roads are at present, only under the direction of a distinct set of commissioners, who should have the superintendence of everything that concerns this species of roads only. These commissioners should be vested with authority under an act of parliament, to erect turnpikes upon them, to levy certain stipulated tolls, and to mortgage the produce of these tolls for the purpose of raising money to be applied in the necessary purcharce of land, and making the roads. In the act it should
should be expressly stipulated, that the produce of these tolls should be applied solely to keeping the road in repair, paying the interest of sums borrowed, and clearing off the principal as fast as the collections would admit; and when the whole money borrowed was thus paid off, the tolls should be lowered as only to produce money sufficient to keep the roads in a state of continually good repair. Thus would the expense of transporting goods be annually diminishing, and the prosperity of the country be thereby augmented from day to day. He adds, that he is particularly earnest in this business, as he has not been an unconcerned observer of the effects that have resulted from the establishment of turnpike roads in Scotland, which were begun within his recollection; and these effects have been such as no man who had not seen it would have believed could ever have taken place. Distant may be paid to be thus diminished from place to place; lands that were originally far beyond the influence of the town as a market for any thing else than live-stock, are thus brought, as it were, close to its gates; and the value of the produce of many articles is thus to them augmented fourfold, while they are at the same time diminished to the public. Not only is the value of produce raised, but the quantity also of that produce is augmented exceedingly by means of manures which become thus accessible. Foliage manures, such as chalk, lime, and marle, which were formerly confined to a narrow spot, expanded themselves as if it were by a magical power, and by that expanifiable influence diffuse around fertility, riches, and plenty. Coals and other weighty articles that may be useful in arts or manufactures of various kinds, which never were, nor ever could have been of any value to the owners of them, now long as the expense of transportation exceeded a certain sum, and a ready market to any extent as soon as the price falls below that rate, thus contributing not only towards the enriching of the owners, but to the furnishing of employment to the various persons who must be engaged in preparing or transporting them to market, and the universal accommodation of the whole. Around every market you may suppose a number of concentric circles drawn, within each of which certain articles become marketable which were not before, and thus become the source of wealth and prosperity to many individuals. Diminish the expense of carriage but one farthing, and you widen the circle; you form, as it were, a new creation, not only of itones, and earth, and trees, and plants, but of men also, and what is more, of industry, of happiness, and joy. It is added, that in making these roads the property of the public, and freeing every person to bring his own waggons upon them wherever he pleased, farmers, who saw in them a road to market leading into these from their respective premises; the inhabitants of villages and country districts would join together, and at one common expense make roads of the fame fort leading to a greater distance inwards, as they now make by roads for themselves. Thus would be all accommodated; those who had businesses enough to furnish a sufficient load for one horse might go to market with it when they pleased: those who had dealings on a smaller scale could have one, two, or more waggons of their own conjoint with those of others to make up a load for one horse: and those of still smaller means could have one wagon loaded with the joint articles belonging to two, three, or more. A ton weight might then be pulled, before a man to market for many miles, as a wheelbarrow is now. It is scarcely possible, he supposes, to contemplate an infititution from which would result a greater quantum of harmony, peace, and comfort, to performers living in the country, than would naturally result from this arrangement. In fact, he knows, he says, no one measure, that would tend so effectually to lower the price of the necessaries of life, and restore abundance.

In what regards the method of forming and constructing these railroads, it is observed by the same writer, that the following has been given by the inventor as the most improved plan: first, that the bed line of the country afforded should be traced out, having regard to the direction of the carriage of articles or trade to be expected; and if such trade be both ways in nearly equal quantities, a line as nearly horizontally as possible should be chosen. If the trade is all in one direction, as is generally the case between mines and navigation, then the most desirable line is one with a gentle gradual descent, such as shall make it not greater labour for the horsemen employed to draw the loaded wagons down, than the empty ones back; and this will be found to be the ease on a railway descending about one foot vertical in one hundred feet horizontal. Or, if the railway and carriages are of the very best contruction, the defcent vertical may be to the length horizontal as 1 to 50, where there is little or no upgade loading. In cafes between mines and navigations the decents will often be found greater than could be withstood. On a railway on the improved plan, where the defcent is more than as 1 to 50, six or eight waggons, loaded with thirty or forty hundred weight each, will have such a tendency to run downwards, as would require great labour of one horse to check and regulate, unless that tendency was checked by flegding some of the wheels. On such, and steeper roads, iron flipers are applied, one or more to a gang of waggons, as occasion may require. Each fliper being chained to the side of one of the waggons, and, being put under the wheel, forms a fledge. Where the descent is very great, steep inclined planes, with machinery, may, it is observed, be adopted, so as to render the other parts of the railway easy. On such inclined planes the defending loaded waggons being applied to raise the ascending empty; or partly loaded ones, the necessity of flegding the wheels is avoided; and the labour of the horse greatly reduced and lessened.

In order to obtain the defired levels, gentle decents, or steep inclined planes, and to avoid sharp turns, and circuitous tracks, it will often be found prudent to cross valleys by bridges and embankments; to cut through ridges of land; and in very rugged countries short tunnels may, be, he thinks, sometimes be necessary. The line of railway being fixed, and the plans and sections by which the fame is to be executed and settled, the ground for the whole must be formed and effectually drained. The breadth of the bed for a single railway, should be, in general, four yards; and for a double one six yards, exclusive of the fences, fide drains, and ramparts.

That the bed of road being to be formed to the proper inclination, and the embankments and works thereof made firm, the surface must be covered with a bed of itones broken small, or good gravel, six inches in thickness at its depth. On this bed must be laid the sleepers, or blocks to fill the rails upon. These should be of stone in all places where it can be obtained in blocks of sufficient size. They should not be less than eight, nor more than twelve inches in thickness; and of such breadth (circular, square, or triangular,) as shall make them 150 lbs. or 200 lbs. weight each. Their shape is not material, so as they have a flat bottom to rest upon, and a small portion of their upper surface level, to form a firm bed for the end of the rails. In the centre of each block should be drilled a hole, an inch and a half diameter, and six inches in depth, to receive an octagonal plug of dry oak, five inches in length; for it should not reach the bottom of the hole; nor should it be larger than fo as to put in easily.
The pliers plug each to receive an iron spike or large nail, with a flat point and long head, adapted to fit the counter-funk notches in the ends of two rails, and thereby to fasten them down in the proper position, or situation in which they are to lie.

With regard to the rails, they should be of the stoutest calk-iron, one yard in length each, formed with a flange on the inner edge, about two inches and a half high at the ends, and three and a half in the centre; and shaped in the belt manner to give strength to the rails, and keep the wheels in their track. The flanges of the rails, for general purposes, should not, he thinks, be less than four inches broad; and the thickness proportioned to the work they are intended for.

On railways for heavy burden, great use; and long duration, the rails should be very stout, weighing 40lbs., or, in some cases, nearly half an hundred weight each. For railways of less consequence, less weight of metal will do; but it will not be prudent to use them of less than 30lbs. weight each, in any situation exposed to breakage above ground. But it is observed that in mines, and other works under ground, where very small carriages only can be employed, very light rails are used, forming what are called train roads, on a system introduced by Mr. Carr; and these kinds of light railways have been much used above ground in Shropshire, and other counties where coals and other minerals are obtained.

It is added, that in fixing the blocks and rails great attention is required to make them firm. No earth or soft materials should be used between the blocks and the bed of small stones or gravel, on which the rails must all be fixed by an iron gage, to keep the tides at a regular distance, or parallel to each other. The belt width of road for general purposes is four feet two inches between the flanges of the rails; the wheels of the carriages running in tracks about four feet six inches apiece. Rails of particular forms are necessary where roads branch out from or intersect each other; and where carriage roads cross the railways; and, at turnings of the railways, great care is required to make them perfectly easy. The rails of the side forming the inner part of the curve should be fixed a little lower than the other; and the rails should be left a little under the gage, so as to bring the tides nearer together than in the straight parts; these deviations in level and width to be in proportion to the sharpness of the curve. The blocks and rails being fixed and spiked fast, nothing more remains to be done than to fill the outsides, or space between the blocks, with good gravel, or other proper materials; a little of which must also be put on the side of the blocks to keep them in their proper places. This gravel should always be kept below the surface of the rails on which the wheels are to run, to keep the tracks of the wheels free from dirt and obstructions. The form of the rails must be such as will free them from dirt if the grannelling is kept below their level.

And in the constructing of the carriages great attention to avoid friction is necessary, particularly in the formation of the wheels and axles, which must be adapted to the form of railways and kind of loading; but for which general directions cannot be given in a narrow compass. It is probable that this valuable invention may also be applicable to many other purposes in agriculture or manufactures, as it becomes more fully understood, and the facilities which it affords are better known. See Canal.

RAIMALPOUR, in Geography, a town of Hindoostan, in Vihapour; 15 miles E. of Sutera.

RAIMONDI, Ignatius, in Biography. This worthy musical professor, whose performance, character, and private virtues, are well known to our country, after a residence in it of more than thirty years, is honourably mentioned by Ernst Ludwig Gerber, the continuator of Walther’s Musical Lexicon, in 2 vols. 8vo., 1792. He says, that this expressive and pleasing performer on the violin, and agreeable composer for his instrument, was born in Italy, a scholar of Barbella, settled at Amsterdam in 1772, where he remained the principal violin during twelve years, having succeeded the famous Locatelli. He had published nine different works for violins at Berlin and Amsterdam, before the year 1785. About the year 1773 he arrived in London, since which time he has published many pleasing compositions, particularly his “Battaglia,” which is the bellicose instrumental music of that kind that has come to our knowledge.
the rain is impetuous. Hence it appears that the vapours are condensed when the atmosphere is warm as well as when it is cold.

Others only allow the cold a part in the action, and ascribe a share of it to the winds, alleging, that a wind blowing against a cloud will drive its vehicle upon one another, by which means several of them, coalescing as before, will be enabled to descend; and the effect will be still more considerable, if two opposite winds blow together toward the same place. To which they add, that clouds already formed, happening to be augmented by fresh accessions of vapour, continually ascending, may on this account be enabled to descend.

Against the above flatly hypothesised of Derham, it has been objected that the vehicle of vapour, if they be such, are filled, not with air, but fire or heat in a latent state, and till they part with this heat, the vapour cannot be condensed. Cold is not always sufficient to produce this effect, for in the most severe frosts the air is terrene, and parts with little or none of its vapours, for a considerable time. It is also alleged, that winds have no considerable agency, since blowing upon vapour is so far from condensing it, that it unites more closely with the air; and wind is known very much to promote evaporation. See VAPOUR.

Yet the grand cause, according to Rohault, still remains: that author conceives it to be the heat of the air, which after continuing for some time near the earth, is at length carried up high by a wind, and there thawing the snowy villi, or flocks of the half-frozen vehicle, reduces them into drops; which coalescing, descend, and have their dissolution perfected in their progress through the lower and warmer plages of the atmosphere. Others, as Dr. Clarke, &c. ascribe this descent of the clouds rather to an alteration of the atmosphere than of the vehicle; and suppose it to arise from a diminution of the spring, or elastic force of the air.

This elasticity, which, as they say, depends chiefly or wholly on the dry terrene exhalations, being weakened, the atmosphere sinks under its burden, and the clouds fall, on the common principle of precipitation.

Now, the little vehicle, by any or all these means, being once upon the descent, will perforce therein, notwithstanding the increase of rainfall they every moment meet with in their progress through still denser and denser parts of the atmosphere. For, as they all tend toward the same point, viz. the centre of the earth, the farther they fall, the more coalescences will they make, and the more coalescences, the more matter there will be under the same surface; the surface only increasing as the squares; but the solidity as the cubes; and the more matter under the same surface, the less friction or salience there will be to the same matter.

Thus if the cold, the wind, &c. happen to act early enough to precipitate the ascending vehicle, before they are arrived at any considerable height, the coalescences being few in so short a descent, the drops will be proportionably small: and thus is formed what we call dew. See DREW.

If the vapours prove more copious, and rise a little higher, we have a MIST or FOG; which see respectively.

A little higher still, and they produce a small rain, &c. If they neither meet with cold, nor wind enough to condense or dissipate them, they form a heavy, thick, dark sky; which lasts sometimes several weeks. This hypothesis of the diminution of the atmosphere's elasticity, requires a more satisfactory explanation of the cause of this diminution. By ascribing it to terrene exhalations, we only solve one difficulty by introducing another; for we are totally un-acquainted with the nature and operation of those exhalations. But let the cause be what may be supposed, if it act equally, and at once, upon all the vapour in the air, all that vapour must be at once precipitated; and the consequence must be, that, instead of gentle showers continuing for a considerable time, we must have copious water-spouts, lasting only for a few minutes or seconds, which, instead of refreshing the earth, would drown and lay it waste.

Those who admit either of the above hypotheses, account for many of the phenomena of the weather; e. g. why a cold is always a wet summer, and a warm a dry one; because the principle of precipitation obtains in the one case, and is wanting in the other. Why we have ordinarily most rain about the equinoctes; because the vapours arise more plentifully than ordinary in the spring, as the earth becomes leesened from the brimful conduplications; and because, as the sun recedes from us in autumn, the cold increasing, the vapours that have lingered above during the summer heats, are now dispatched down, &c. Why a settled, thick, clothe sky fiercely ever rains till it have been first clear; because the equally diffused vapours must first be concentrated, and congregated into separate clouds, to lay the foundation of rain; by which means the res of the face of heaven is left open, and pervious to the rays of the sun, &c.

For other phenomena of rain, as they relate to the weather-glass, see BAROMETER, and WEATHER. It cannot be doubted, that there is a connection between the centre of the barometer and the fall of rain; but no satisfactory reason has yet been assigned for the circumstance; nor is it possible to foretell with certainty that rain will follow any changes in the height of the barometer that have been observed. The immediate dependence of rain, or of any other atmospheric phenomena, on the influence of the moon, appears to be rendered highly improbable, not only by mathematical calculations of the effects of the moon's attraction, but also by the irregularity of the observations which have been adduced in favour of a such a connection. (See Influence of the Moon.) But however uncertain the ultimate causes of rain may be in general, their effects in some places are sufficiently constant, to be attributed to permanent local circumstances, and in particular to the periodical recurrence of similar winds.

For a more particular account of other theories, for explaining the ascent of vapours, the formation of clouds, and the fall of rain, see VAPOUR.

Besides the cause of rain, mentioned above, Desaguliers thinks it owing to the loss of electricity in the vapours of which they were formed.

Other writers, in the progress of this part of philosophical science, have considered rain as an electrical phenomenon; or at least they have supposed, that the powers of electricity may concur with other causes in producing it. Signior Beccaria, whose observations on the general state of electricity in the atmosphere have been more extensive and accurate than those of any other person, reckons rain, hail, and snow, among the effects of a moderate electricity in the atmosphere. Clouds that bring rain, he thought, were produced in the same manner as thunder-clouds, only by a moderate electricity. He describes them at large, and the resemblance which all their phenomena bear to those of thunder-clouds is very striking. He notes several circumstances attending rain without lightning, which render it probable, that it is produced by the same cause as when it is accompanied with lightning. Light has been seen among the clouds by night in rainy weather; and even by day rainy clouds are sometimes seen to have a brightness evidently independent of the sun. The uniformity with which
RAIN.

which the clouds are spread, and with which the rain falls, he thought, were evidences of an uniform cause like that of electricity. The intensity also of electricity in his apparatus generally corresponded very nearly to the quantity of rain that fell in the same time. Sometimes all the phenomena of thunder, lightning, hail, rain, snow, and wind have been observed at one time; which shows the connection they all have with some common cause. Signior Beccaria, therefore, supposes, that, previous to rain, a quantity of electric matter escapes out of the earth, in some places where there was a redundancy of it; and in its ascent to the higher regions of the air, collects and conducts into its path a great quantity of vapours. The same cause that collects, will condense them more and more; till, in the places of the nearest intervals, they come almost into contact, so as to form small drops; which, uniting with others as they fall, come down in rain. The rain will be heavier in proportion as the efficacy is more vigorous, and the cloud approaches more nearly to a thunder-cloud. He imitated the appearance of clouds that bring rain, by inflating himself between the rubber and conductor of his electrical machine; and with one hand dropping colophonia into a pitoon fastened to the conductor, and holding a burning coal, while his other hand communicated with the rubber. In these circumstances the smoke spread along his arm, and, by degrees, all over his body, till it came to the other hand that communicated with the rubber. The lower surface of this smoke was everywhere parallel to his clothes, and the upper surface was welted and arched like clouds replete with thunder and rain. In this manner, he supposes, the clouds that bring rain diffuse themselves from over those parts of the earth which abound with electric fires, to those parts that are exhausted of it; and by letting fall their rain, restore the equilibrium between them. Signior Beccaria also thought, that the electricity communicated to the air, which both receives and parts with it slowly, would account for the retention of vapours in a clear sky; for small disjointed clouds, not dispersed into rain; for the smaller and lighter clouds in the higher regions of the air, which are but little affected by electricity; and also for the darker, heavy, and sluggish clouds in the lower regions, which retain more of it. He even imagined that some alteration in the weight of the air might be made by this electricity of it: the phenomena of rain, he thought, favoured the supposition, that the electric matter in the air did, in some measure, lessen its pressure: for when the electric matter is actually in the air, collecting and condensing the vapours, the barometer is low. When the communication is made between the earth and the clouds by the rain, the quicksilver begins to rise; the electric matter, which supported part of the pressure, being discharged.

Dr. James Hutton's theory of rain is elaborated and ampli- illustrated in the 1st volume of the Edinburgh Transactions, p. 47, &c. It is well known that atmospheric air is capable, with a certain degree of heat, of dissolving a given quantity of water. (See VAPOUR.) Dr. Hutton ascertains the ratio of the dissolving power of air, in relation to water, with different degrees of heat; and thus, by mixing a portion of transparent humid warm air with a portion of cold air, the mixture becomes opaque, and part of the water will be precipitated; or, in other words, the vapour will be condensed into rain. Hence he observes, that since the capacity of air for moisture increases faster than the temperature, there must be a depression of moisture when two saturated portions of air at different temperatures are mixed. Dr. Hutton supposes that heat and solution do not increase by equal increments; but that, in reality, if heat be supposed to increase by equal increments along a straight line, solution will be expressed by ordinates to a curve, whose convex side is turned towards that line. That the power of solution is not increased in the same ratio with heat is, however, hypothetical, except when we rise pretty high in the scale, when its proportional increase is some what doubtful; nor has our author supported it by experiment. The condensation of the breath in air is not to the purpose, unless we suppose the air to be already satu rated with vapour. In any view, it can only amount to this, that to render it visible, the heat must be diminished in a greater proportion than can be compensated by the power of solution in the body of air, in which the portion expired is at first immered. In order to explain the origin of rain from this cause, we must always suppose a constant diminution of heat to take place at the moment of the condensation of the vapour; but we actually find, that the change from a state of vapour to the fluid state is attended with heat; so that rain must at once oppose its own caufe, and continued rains would be impossible without the aid of other causes. Dr. Hutton endeavours, from his own system, to explain the regular and irregular leasons of rain, with regard either to the generality of its appearance, or the regularity of its return. And to obviate the apparent exceptions of the theory, from the generality of rain, he explains the proportional quantities of rain, and adds a comparative estimate of climates, in relation to rain with the meteorological ob servations made in our own climate. As our limits will not allow our doing full justice to our author's reasoning, we must refer to his own paper on the subject.

Mr. Dalton, in his "Meteorological Essays," (Eff. vi.) expresses his approbation of Dr. Hutton's theory in general; to this purpose, he says, "the principles of none appear to me to be more plausible and consistent with facts." Dr. Hutton, as we have above shown, confines the varieties of heat and cold, affecting the soluble power of the atmosphere, as the sole causes of rain; and Mr. Dalton observes, when we consider that evaporation and the precipitation of vapour are diametrically opposite, it is reasonable to suppose that they should be promoted by opposite causes: and as heat and dry air are favourable to evaporation, so cold, operating upon air replete with vapour, promotes its precipitation. Dr. Hutton, however, seems to consider water as chemically combined with the atmosphere, and that cold produces precipitation in a manner similar to what it does in water saturated with salt, or in other chemical processes; whereas Mr. Dalton supposes, that a portion of the vapour, considered as a distinct and peculiar fluid, is condensed into water by cold; but the effects resulting from the two theories will be the same. See Meteorology, and VAPOUR.
make the hygrometer move towards: humidity, in proportion as the vapour is more or less abundant in the air: on a diminution of heat, the humidity, as shown by the hygrometer, must increase; and on an increase of the heat, the humidity must diminish; and the introduction of other hygroscopic submstances, drier than the air, must have the same effect as an augmentation of heat. These are the properties of vapour, on every hypothesis of evaporation; and, therefore, all the water that exists in the atmosphere, without poffeeling these properties, is no longer vapour, but must have changed its nature. M. de Luc shews, that the water which forms rain, though it has ever been confidered and reafoned upon as producing humidity, does not poffefs this property, and, therefore, have paffed into another state. As he thinks that the vapour paffes into an invi{ible} state in the interval between evaporation and its falling again in rain, and that in this state it is not fenfible to the hygrometer, he considers the laws of hydrology as insufficient for explaining the formation of rain; but he does not pretend to have discovered the immediate cause of the formation of clouds and rain. If it is not in the immediate product of evaporation that rain has its source; if the vapours change their nature in the atmosphere, fo as no longer to be fenfible to the hygrometer, or to the eye; if they do not become vapour again till clouds appear; and if, when the clouds are formed, no alteration is perceived in the quality of the air; we must acknowledge it to be very probable, that the intermediate state of vapour is no other than air, and that the clouds do not proceed from any different fluid contained in the atmosphere, but from a decomposition of a part of the air itself, perfectly similar to the refi. For other observations on the nature and quality of vapour, and the subsequent formation of rain, we refer to the articles Meteorology, and Vapour.

As to the general quantity of rain that falls, and its proportion in several places at the same time, and in the same place at several times, we have many observations, journals, &c. in the Memoirs of the French Academy, the Philof. Tranf. and many other publications; from which we shall make the following extracts.

Upon measuring the rain falling yearly, its depth, at a medium, is found as in the following table.

Depth of Rain falling yearly, and its Proportion in several Places.

Half Year 36.76 19.24 32.66

As rain-gages have been fixed of late years in almost every part of the kingdom, we are enabled to determine, with considerable exactness, the depth of water which the rain yields in any given place. It may be observed, however, that inland counties have less rain than maritime ones, especially those which border on the western seas. But still a greater difference seems to take place between a mountainous country, and a champagne or flat country. In the former there often falls double or triple the quantity of rain in a year that there does in the latter, and never less than an equal quantity. It is also observed, that these winds bring most rain that blow from the quarter in which is the mott and nearest sea; as are west and south-west winds. The rain-gage also shews, that more rain is collected in the instrument, as it is placed nearer the ground; without any appearance of a difference, between two places, on account of their difference of level above the sea, provided that the instrument is as far from the ground at the one place, as it is at the other. These effects are noticed in the Phil. Tranf. for 1769 and 1771, the former by Dr. Heberden, and the latter by Mr. Daines Barrington. Dr. Heberden says, "A comparison having been made between the quantity of rain which fell in two places in London, about a mile distant from one another, it was found that the rain in one of them constantly exceeded that in the other, not only every month, but almost every time that it rained. The apparatus used in each of them was very exact, and both made by the same artift; and upon examining every probable cause, this unexpected variation did not appear to be owing to
The inference to be drawn from these experiments, Mr. Barrington observes, seems to be, that the increase of the quantity of rain depends upon its nearer approximation to the earth, and scarcely at all upon the height of places, provided the rain-gages are fixed at about the same distance from the ground.

Possibly also a much controverted point between the inhabitants of mountains and plains may receive a solution from these experiments; as in an adjacent valley, at least, very nearly the same quantity of rain appears to fall within the same period of time as upon the neighbouring mountains.

Dr. Heberden also adds the following note. "It may not be improper to subjoin to the foregoing account, that in places where it was first observed, a different quantity of rain would be collected, according as the rain-gages were placed above or below the tops of the neighbouring buildings; the rain-gages below the top of the house into which the greater quantity of rain had for several years been found to fall, was above fifteen feet above the level of the other rain-gage, which, in another part of London, was placed above the top of the house, and into which the lesser quantity always fell. This difference, therefore, does not, as Mr. Barrington justly remarks, depend upon the greater quantity of atmosphere through which the rain descends: though this has been supposed by some, who have hitherto concluded that this appearance might readily be solved by the accumulation of more drops, in a different through a great depth of atmosphere."

In the examination of the results from meteorological tables, it should be observed, that several years' account of the rain at any place is required, before a medium yearly quantity can be obtained with sufficient accuracy. The following table, formed by Mr. Dalton, and published in the first part of the fifth volume of Manchester Memoirs, gives us the largest collection of accounts of rain fallen in different places in England that has to our knowledge hitherto appeared. They are chiefly taken from the Transactions of the Royal Society, and of other societies.

**General mean:** 35.2 inches

The general mean of 35.2 inches is, as our author apprehends, a little above the medium for England and Wales, as the greater number of places is those where much rain falls. If we take up a mean for each of the above-mentioned counties, (where more than one place in a county is given,) and then a general mean from the counties, the result is a reduced mean of 31.3. Even then it may be objected, that the greater part of the counties are maritime; but it must be observed, that there is no account of rain in Wales; and we may safely conclude, that the rain in Wales would exceed the last-mentioned mean as much as the inland counties of England, not in the above hit, would fall short; because Wales is both a mountainous country, and exposed to the sea.

We will, therefore, conclude, that the mean annual depth of rain in England and Wales, deduced from these twenty counties, is 31 inches: a quantity which sublubient observations, our author is confident, will diminish, and probably not increase much.

The editors of the Encyclopaedia, under the article *Weather,* from 16 places of observation, make the annual mean for Great Britain 32.53 inches; and M. Cottet, in the *Journal de Physique* for 1791, gives a mean derived from 147 places, in different parts of the world, equal to 34.7 inches.

If we take the dew (see *Dew*) at 5 inches annually, we shall have 36 inches of water at a medium annually, on the surface of the earth, in England and Wales, reckoning 31 for rain and 5 for dew. Admitting the computation of Guttir, the area of England and Wales is 46,450 square miles. This, reduced to square feet, gives 1,378,586,850,000; which, multiplied by 3 feet, the annual depth of rain and dew, gives 4,135,760,600,000 cubic feet of water, = 153,176,320,000 cubic yards, or 28 cubic miles = 115 thousand millions of tons in weight, nearly. This immense mass of water is dispersed partly by the supply of rivulets, and the soaking into the earth a small way, so as to break on again in lower ground in the form of springs, and then make its way to some rivers, by which it is conveyed to the sea: and partly the means rainfall into the atmosphere, in the process of evaporation. The decomposition of water by vegetables is not noticed, because it is presumed that in the course of nature the principles are combined, and water formed again. See River, Spring, Evaporation, and Vapour.

As to the use of rain, we may observe that it moistens and softens the earth, and thus suits it for affording nourishment to plants: by falling on high mountains, it carries down with it many particles of loose earth, which serve to fertilize the surrounding valleys, and purifies the air from noxious exhalations, which tend in their return to the earth to meliorate the soil; it moderates the heat of the air; and is one means of supplying fountains and rivers. However, vehement rains in many countries are found to be attended with barrenness and poorfands of the lands, and miscarrage of the crops in the succeeding year; and the reason is plain; for these excessive storms wash away the fine mould into the rivers, which carry it into the sea, and it is a long time before the land recovers itself again. The remedy to the famine, which some countries are subject to from this fort of mischief, is the planting large orchards and groves of such trees as bear effulent fruit; for it is an old observation, that in years, when grain succeeds work, these trees produce mulf fruit of all. It may partly be owing to the thorough moistening of the earth, as deep as their roots go, by these rains, and partly to their trunks flopping part of the light mould carried down by the rains, and by this means furnishing themselves with a coat of new earth. Phil. Trans. No 90.

The water afforded by rain is found highly refreshing to almost all sorts of vegetable crops, and to promote their growth in a rapid manner, when not produced in too great abundance at a time. This effect, which may often be perceived to take place in a sudden manner, after warm showers in the early spring months, is probably caufed by the large proportion of oxygen that is contained in rain-water, as well as from the necessary moisture being afforded to the fibres of the roots of the plants. Too much rain may be injurious, however, by lefening the necessary cohesion and compactness of soils, by which they may not afford proper firmness to the roots of growing vegetables. And another injury may be produced by the too frequent occurrence of hafly showers, by which a large proportion of the decomposing vegetable and animal materials of lands, which are soluble or diffusible in water, may be conveyed away into the ditches, rivers, and ultimately into the sea, and of course prove the cause of infertility. In hilly situations, this effect may arise from even light showers; on which account, they have been advised to be plumged in a planting direction, as by that means the rains may be more perfectly detained in the soils. And it has been suggested by Dr. Darwin, that as the foliage or birds of plants require more moisture for their vigorous growth than their flowers, in this climate, continued rains may be liable not only to wash off the farina from
from the burbling anthers, and in that way prevent the impregnation of the pistillum, but also delay the ripening of the seeds or fruit, from the want of a due evaporation of their permeable matter, as well as from the less solar light in cloudy seasons. On this account it is, he supposes, that in the north of Scotland the oats are said seldom to ripen till the frosts commence, with the dry season which accompanies it.

Thus, as the effects of rain are so very considerable on vegetation, it would be highly useful to ascertain the quantity or depth of rain that falls annually in different districts, and the difference in the effects which are produced by it. See Water and Weather.

The vast quantities of rain which fall in some districts, from the peculiar nature of their situations, especially where they are of the grazing or pasture kind, as those of Cheshire, Lancashire, and some others, are often highly beneficial to their general fertility; the natural grassy pastures of which districts, though frequently of inferior qualities to those in many other places, are, in consequence of this circumstance, rendered superior in their abundance of grass, the strength of its vegetation, and the richness of its quality. The former of the above counties may indeed, without any impropriety, be reckoned one of the most productive grass-land districts in the kingdom, as is fully evinced by the great abundance and inferiority of its dairy production. The grassy lands in this tract of country mostly retain their full verdure during the moist sultry and parching seasons, except where they are of a sandy or gravelly nature in their under strata. Where they are near to the sea, however, in this as well as other parts, they are liable to become mossy, or be covered with the moist plant, either in consequence of so much of the spray from it falling in the manner of light rain, or some other cause of that kind.

The quantity of rain falling upon land has much influence upon its temperature, or state of heat, and, of course, great effect on vegetation in that way; and the nature of its mixture with it, or the manner in which it is distributed through its parts, or combined with its different earthy materials, is another means by which it becomes of great importance, as it relates to the supplying of nourishment and support to vegetables as crops.

Rain falling in large quantities, on particular sorts of retentive soils, is a frequent cause of that kind of injurious wetness, which tends so much in need of surface-draining to remove. See Surface-DRAINING.

The nature and causes of showers and rain are extremely curious and interesting in several different points of view, both to the agriculturist and the philosophical inquirer.

RAINS, PRETENatural. We have numerous accounts in historians of preternatural rains, such as the raining of stones, of dust, of blood, of mud, of living animals, as young frogs, and the like. We are not to doubt the truth of what those who are authors of veracity and credit relate to us of this kind, so far as to suppose that the FALLING of STONES (which see) and dust never happened; the whole mistake (if it he so with regard to the first instance) is the supposing them to have fallen from the clouds; but as to the blood and frogs, it is very certain that they never fall at all, but the opinion has been a mere deception of the eyes. Men are extremely fond of the marvellous in their relations; but the judicious reader is to examine strictly whatever is reported of this kind, and is not to suffer himself to be deceived.

There are two natural methods by which quantities of stones and dust may fall in certain places, without their having been generated in the clouds, or fallen as rain. The one is by means of hurricanes: the wind which we frequently see tearing off the tiles of housetops, and carrying them to considerable distances, being equally able to take up a quantity of stones, and drop them again at some other place. But the other, which is much the most powerful, and probably the most usual way, is for the eruptions of volcanos, and burning mountains, to toss up, as they frequently do, a vast quantity of stones, ashes, and cinders, to an immense height in the air; and these being hurried away by the hurricanes and impetuous winds, which usually accompany those eruptions, and being in themselves much lighter than common stones, as being half calcined, may easily be thus carried to distant districts, and their falling in places where the inhabitants know nothing of the occasion, they cannot but be suspected by the vulgar to fall on them from the clouds. It is well known, that in the great eruptions of Etna and Vesuvius, showers of ashes, dust, and small cinders, have been seen to obscure the air, and spread a cloud of the air for a great way, and cover the decks of ships; and this at such a distance, as it should appear strange conceivable that they should have been carried to; and probably, if the accounts of all the showers of these sublunations mentioned by authors be collected, they will all be found to have fallen within such distances of volcanos; and if compared, as to the time of their falling, will be found to correspond in that also with the eruptions of those mountains. We have known instances of the ashes from Vesuvius having been carried thirty, nay forty leagues, and peculiar accidents may have carried them yet farther.

The raining of blood has been ever accounted a more terrible sight, and a more fatal omen, than the other preternatural rains already mentioned. It is very certain that nature forms blood no where but in the vessels of animals, and therefore showers of it from the clouds are by no means to be credited. Those who suppose that what has been taken for blood, has been actually been falling from the air, have had recourse to flying insects for its origin, and suppose it the eggs or dung of certain butterflies discharged from them as they were high up in the air. But this seems a very wild conjecture, as we know of no butterfly whose excrement, or eggs, are of such a colour, or whose abode is so high, or their flocks so numerous, as to be the occasion of this.

It is most probable that these bloody waters were never seen falling, but the people seeing the standing waters blood-red, were allured, from their not knowing how it should else happen, that it had rained blood into them. A very memorable instance of this there was at the Hague in the year 1670. Swammerdam, who relates it, tells us, that one morning the whole town was in an uproar, on finding their lakes and ditches full of blood, as they thought, and having been certainly full of water the night before, they agreed it must have rained blood in the night; but a certain physician went down to one of the canals, and taking home a quantity of this blood-coloured water, he examined it by the microscope, and found that the water was water still, and had not at all changed its colour, but that it was full of prodigious swarms of small red animals, all alive, and very nimble in their motions, whose colour and prodigious number gave a red tinge to the whole body of the water they lived in, on a less accurate inspection. The certainty that this was the fact, did not however persuade the Hollanders to part with the miracle; they prudently concluded, that the sudden appearance of such a number of animals was as great a prodigy as the raining of blood would have been; and are allured at this day, that this portent foretold the scene of war and devastation which Lewis XIV. afterwards brought into that country, which had before enjoyed forty years uninterrupted peace.
The animals, which thus colour the water of lakes and ponds, are the *pallea argentea* of Swammerdam, or the water-fleas with branched horns. These creatures are of a reddish-yellow, or flame colour; they live about the sides of ditches, under weeds, and among the mud, and are therefore the less visible, except at a certain time, which is in the end of May or beginning of June: it is at this time that these little animals leave their receptacles to float loose about the water, to meet for the propagation of their species, and by that means become visible in the colour they give the water. This is visible, more or less, in one part or other of almost all standing waters at this season; and it is always at this season that the bloody waters have alarmed the ignorant.

The rising of frogs is a thing not less wonderful in the accounts of authors who love the marvellous, than those of blood, or of stones; and this is supposed to happen so often, that there are multitudes who pretend to have been eye-witnesses of it. These rains of frogs always happen after very dry seasons, and are much more frequent in the hotter countries than the cold ones. In Italy they are very frequent; and it is not uncommon to see the streets of Rome swarming both with young frogs and toads in an instant, in a shower of rain; they hopping everywhere between the people's legs, as they walk, though there was not the least appearance of them before. Nay, they have been seen to fall through the air down upon the pavements. This seems a strong circumstance in favour of their being rained down from the clouds, but when strictly examined, it comes to nothing; for these frogs, that are seen to fall, are always found dead, lamed, or bruised by the fall, and never hop about as the rest; and they are never seen to fall, except close under the walls of houses, from the roofs and gutters of which they have accidentally slipped down.

To the rising of frogs we ought to add the rising of grasshoppers and locusts, which have sometimes appeared in prodigious numbers, and devoured the fruits of the earth. There has not been the least pretence for supposing that these animals descended from the clouds, but that they appeared on a sudden in prodigious numbers. The naturalist, who knows the many accidents attending the eggs of these, and other like animals, cannot but know that some of these frogs will prove particularly favourable to the hatching of them, and the prodigious number of eggs that many insects lay, could not but every year bring us such abundance of the young, as they were not liable to many accidents, and had not provident nature taken care, as in many plants, to continue the species by a very numerous flock of seeds, of which perhaps not one in five hundred need take root, in order to continue an equal number of plants.

The rising of fishes has been a prodigy also much talked of in France, where the streets of a town at some distance from Paris, after a terrible hurricane in the night, which tore up trees, blew down houses, &c. were found in a manner covered with fishes of various sizes. Nobody here made any doubt of these having fallen from the clouds; nor did the absurdity of fish, or of five or six inches long, being generated in the air, at all trouble the people, or shake their belief in the miracle, till they found upon enquiry that a very well-stocked fish-pond, which stood on an eminence in the neighbourhood, had been blown dry by the hurricane, and only the great fish left at the bottom of it, all the smaller fry having been tolled into their streets.

Upon the whole, all the supposed marvellous rains have been owing to substances naturally produced on the earth, and either never having been in the air at all, or only carried thither by accident.

Vol. XXIX.
the rain at a little more than one hundred feet above the level of the sea; accounts of which have been regularly kept since the year 1781; but previously to that period the rain was measured by an old rain-gage. It is to be regretted, however, that the exact nature of this invention is not more fully explained; and that other cheap plain inventions of this nature are not better known to the farmer.

RAIN-WATER. See Water.

Rains, in the Sea Language, denote all that trash of sea to the northward of the equator, between four and ten degrees of latitude; and lying between the meridian of Cape Verde and that of the eastermost islands of the same name.

It takes its name from the almost continual rains, constant rains, and thunder and lightning, to a great degree, always found there. The winds, when they do blow, are only small uncertain gusts, and shift about all round the compass; to that ships are sometimes detained here a long while, and can make but very little way.

RAINANGBONG, in Geography, a town of the Birman empire, situated near a river in which there are several wells of petroleum, whence its name signifying a town through which flows a river of earth-oil. N. lat. 20° 26'. E. long. 94° 46'.

RAINBOW, Iris, or, simply, the bow, a meteor in form of a parti-coloured arch, or semicircle, exhibited in a rainy sky, opposite to the sun, by the refraction of his rays in the drops of falling rain.

There is also a secondary, or fainter bow, usually seen invelling the former at some distance. Among naturalists, we also read of lunar rainbows, marine rainbows, &c.

The rainbow, fir Isaac Newton observes, never appears but where it rains in the sun-shine; and it may be represented artificially by contriving water to fall in little drops, like rain, through which the sun shines, exhibiting a bow to a spectator placed between the sun and the drops; especially if a dark body, e. g. a black cloth, be disposed beyond the drops.

That the rainbow is opposite to the sun, has always been observed. It was, therefore, natural to imagine, that the colours of it were produced by some kind of reflection of the rays of light from drops of rain or vapour. The regular order of the clouds was another circumstance that could not have escaped the notice of any person. But though more reflection had in no other cafe been observed to produce colours, and it could not but have been observed that reflection is frequently attended with that phenomenon, so that some of the ancients, as we learn from Aristotle’s tract on meteors, knew that the rainbow was caused by the refraction of the sun’s light in drops of falling rain; yet no person seems to have thought of having recourse to a proper refraction in this case before one Fletcher of Breflaw, who, in a tract which he published in 1571, endeavoured to account for the colours of the rainbow by means of a double reflection, and one reflection. But he imagined that a ray of light, after entering a drop of rain, and suffering a refraction, both at its entrance and exit, was afterwards reflected from another drop, before it reached the eye of the spectator. He seems to have overlooked the refraction at the farther side of the drop, or to have imagined that all the bendings of the light within the drop would not make a sufficient curvature, to bring the ray of the sun to the eye of the spectator. Antonio de Dominis, bishop of Spalato, whose tract, "De Radius Vhls et Lucis," was published by I. Bartoli, in 1611, was the first person who advanced, that the double refraction of Fletcher, with an intervening reflection, was sufficient to produce the colours of the rainbow, and also to bring the rays that formed them to the eye of the spectator, without any subsequent reflection. He distinctly describes the progress of a ray of light entering the upper part of the drop, where it suffers one refraction, and after being thereby thrown upon the back part of the inner face, is from thence reflected to the lower part of the drop; at which place undergoing a second refraction, it is thereby bent so as to come directly to the eye. To verify this hypothesis, he procured a small globe of flagggs, and viewing it when it was exposed to the rays of the sun, in the same manner in which he had supposed that the drops of rain were situated with respect to them, he actually observed the same colours which he had seen in the true rainbow, and in the same order. The theory of A. de Dominis was adopted, and in some degree improved, by Descartes. Philosophers were, however, for a long time at a loss when they endeavoured to assign reasons for all the particular colours, and for the order of them. Indeed, nothing but the doctrine of the different refrangibility of the rays of light, which was a discovery referred for the great Sir Isaac Newton, could furnish a complete solution of this difficulty.

Dr. Barrow, in his "Lecciones Opticas," (Lect. 12. n. 14.) says, that a friend of his, meaning Mr. Newton, communicated to him a method of determining the angle of the rainbow, which was hinted to Newton by Sluëns, without making a table of the refractions, as Descartes did. The doctor shews the method, with other curious particulars. But the subject was given more perfectly by Newton afterwards, in his "Optics," prop. 9; where he makes the breadth of the interior bow to be nearly 2° 15', that of the exterior 3° 45', their distance 8° 25', the greatest diameter of the interior bow 42° 17', and the least of the exterior 50° 42', when their colours appear strong and perfect.

RAINBOW, Theory of the. To conceive the origin of the rainbow, let us consider what will befall rays of light coming from a very remote body, e. g. the sun, and falling on a globe of water, such as we know a drop of rain to be.

Suppose, then, A D K N (Plate XVIII. Optics, fig. 1.) to be a drop of rain, and the lines E F, B A, O N, to be rays of light coming from the centre of the sun; which, on account of the immense distance of the sun, we conceive to be parallel.

Now the ray B A being the only one that falls perpendicularly on the surface of the water, and all the rest obliquely, it is easily inferred, that all the other rays will be refracted towards the perpendicular. (See Refraction.) Thus the ray E F, and others accompanying it, will not go on straight to G; but as they arrive at H I, they will deflect from F to K; where some of them, probably, escaping into the air, the rest are reflected upon the line K N, so as to make the angles of incidence and reflection equal.

Further, as the ray K N, and those accompanying it, fall obliquely upon the surface of the globe, they cannot pass out into the air, without being refracted, so as to recede from the perpendicular L M; and, therefore, they will not proceed straight to Y, but will deflect to P.

It may be here observed, that some of the rays, arriving at N, do not pass out into the air, but are again reflected to Q; where being refracted, like the rest, they do not proceed right to Z; but, declining from the perpendicular T V, are carried to R; but since we here only regard the rays as they may affect the eye placed a little below the drop, e. g. at P, those which deviate from N to Q, we let aside, as useless; because they never come to the eye.

On the contrary, it is to be observed, that there are other rays,
RAINFALL.

rays, as 2 3, and the like; which, being refracted from 3 to 4, and reflected to 5, and from 5 to 6, may at length, by refraction at 6, arrive at the eye; placed beneath the drop.

Thus much is obvious; but to determine precisely the quantities of refraction of each ray, there must be a calculation; by such calculation it appears, that the rays which fall on the quadrant A D, are continued in lines, like those here drawn in the drop A D K N; wherein there are three things very considerable: first, that the two refractions of the rays, in their ingress and egress, are both in the same way; so that the latter does not destroy the effect of the former. Secondly, that of all the rays passing out of A N, N P, and those adjoining to it, are the only ones capable of affecting the eye, as being sufficiently close and contiguous, and because they come out parallel; whereas the rest are diverging, and dispersed too far to have any sensible effect, at least to produce any thing so vivid as the colours of the bow. Thirdly, that the ray N P has shade or darkens under it; for, since there is no ray comes out of the surface N 4, it is the same thing as if the part were covered with an opaque body. We might add that the same ray N P has darkens above it; since the rays that are above it are inefficual, and signify no more than if there were none at all.

To add to this, that all the effectual rays have the same point of reflection, i.e. the parallel and contiguous rays, which alone are effectual after refraction, will all meet in the same point of the circumference, and be reflected thence to the eyes.

Farther, it appears, that the angle O N P, included between the ray N P, and the line O N drawn from the centre of the fun, is the angle by which the rainbow is distant from the opposite point of the sun, and which makes the semidiameter of the bow. The method of determining it will be seen in the sequel of the article. But since, besides those rays coming from the centre of the sun to the drop of water, there are many more from the several points of its surface; there are a great many other effectual rays to be considered, especially that from the uppermost, and that from the lowest part of the sun's body.

Since, then, the apparent semidiameter of the sun is about 16 minutes, it follows, that an effectual ray from the upper part of the sun will fall higher than the ray E F by 16 minutes; thus does the ray G H (fig. 2), which being refracted as much as E F, deflects to I, thence to L, and at length emerging equally refracted with the ray N P, proceeds to M; and makes an angle O N M with the line O N. In the like manner, the effectual ray Q R coming from the lowest part of the sun, falls on the point R, 16 minutes lower than the point F on which the ray E F falls; and this, being refracted, declines to S, whence it is reflected to T; where, emerging into the air, it proceeds to V; so that the line T V, and the ray O T, contain an angle whose whole magnitude will be ascertained. Again, upon computing the deflections of the rays, which like that 23 (fig. 1.) coming from the centre of the sun, and being received into the lower part of the drop, we have supposed to be twice reflected, and twice refracted, and to enter the eye by lines like that 57 (fig. 3.) we find that which may be accounted effectual, as by with the line 86 drawn from the centre of the sun, contains an angle 867; whence it follows, that the effectual ray from the highest part of the sun, with the same line 86, includes an angle left by 16 minutes; and that from the lowest part of the sun, an angle greater by 16 minutes.

Thus, since A B C D E F is the path of the effectual ray from the highest part of the sun to the eye in F, the angle 86 F becomes of a certain magnitude ascertained below. In like manner, since G H K L M is the way of an effectual ray from the lowest part of the sun to the eye, the angle 86 M becomes greater than the former by 16 minutes.

Since, then, we admit several rays to be effectual, besides those from the centre of the sun, what we have said of the shade will need some alteration; for of the three rays described (figs. 2 and 3), only the two extreme ones will have a shadow joined to them, and that only on the outer side. Hence it is evident, that these rays are perfectly disposed to exhibit all the colours of the prizm.

For the great quantity of deuce or intense light, i.e. the bundle of rays collected together in a certain point, or, in the point of reflection of the effectual rays, may be counted as a lucid or radiant body, terminated around by shade. But the several rays, thus emitted to the eye, are both of different colours; that is, they are fitted to excite in us the ideas of different colours; and are differently refracted out of the water into the air, notwithstanding their falling alike upon the refracting surface.

Hence it follows, that the different or heterogeneous rays will be separated from one another, and will tend separate ways; and the homogeneous rays will be collected, and tend the same way; and, therefore, this lucid point of the drop in which the refraction is effectuated will appear fringed or bordered with several colours; that is, red, green, and blue colours will arise from the extremes of the red, green, and blue rays of the sun, transmitted to the eye from several drops, one higher than another, after the same manner as is done in viewing lucid or other bodies through a prizm.

Thus, adds Sir Isaac Newton, the rays that differ in refrangibility, will emerge at different angles; and, consequently, according to their different degrees of refrangibility, emerging most copiously at different angles, they will exhibit different colours in different places.

A great number, then, of these little globules being diffused in the air, will fill the whole space with these different colours; provided they be so disposed as that effectual rays may come from them to the eye; and thus will the rainbow, at length, arise.

Now, to determine what that dispostion must be, suppose a right line drawn from the centre of the sun through the eye of the spectator, as the line V X (fig. 2.) called the line of apect, or axis of vision; being drawn from to remote a point, it may be esteemed parallel to all other lines drawn from the same point; but a right line, falling on two parallels, makes the alternate angles equal.

If, then, an indefinite number of lines be imagined drawn from the spectator's eye to a part opposite to the sun where it rains; which lines make different angles with the line of aspect, equal to the angles of refraction of the differently refrangible rays, these lines, as rays on drops of rain illuminated by the sun, will make angles of the same magnitude with rays drawn from the centre of the sun to the same drops. And, therefore, the lines thus drawn from the eye will represent the effectual rays that occasion the fenation of any colour.

Now it is known, that the eye, being placed in the vertex of a cone, sees objects upon its surface, as if they were in a circle; and the eye of our spectator is here in the common vertex of several cones, formed by the several kinds of efficacious rays, with the line of aspect. Now in the surface of that whole angle at the vertex, or eye, is the greatest, and in which the others are included, are those drops, or parts of
of drops, which appear red; and in the surface of that cone whose angle is least, are the purple drops; and in the intermediate cones, are the green, blue, &c. drops. Hence, then, several kinds of the drops must appear as if dispersed into so many circular coloured facets, or arches, as we see in the rainbow. (Rohault's System of Nat. Phil. vol. ii. part iii. cap. 17.) This part of the solution first given by Isaac Newton explains more precisely, thus: suppose O (fig. 4.) the eye, and OP a line parallel to the sun's rays; and let POE, POF, be angles of 40° 17', and 42° 2'. And suppose the angles to turn about their common side OP, with their other sides OE and OF, they will describe the bounds, or verges, of the rainbow.

For if E, F be drops placed anywhere in the conical surface described by OE, OF, and illuminated by the sun's rays ES, SF; the angle SEO being equal to the angle POE, or 40° 17', shall be the greatest angle in which the most refrangible rays can, after reflection, be refracted to the eye; and, therefore, all the drops in the line OE shall send the most refrangible rays most copiously to the eye, and therefore strike the fenestrae with the deepest violet colour in that region.

And in like manner the angle SFO being = to the angle POF = 42° 2', shall be the greatest in which the least refrangible rays after one reflection can emerge out of the drops; and these rays shall come most copiously to the eye from the drops in the line OF, and strike the fenestrae with the deepest red colour in that region.

And, by the same argument, the rays which have intermediate degrees of refrangibility shall come most copiously from drops between E and F, and so strike the fenestrae with the intermediate colours, in the order which their degrees of refrangibility requires; that is, in the progress from E to F, or from the inside of the bow to the outside, in this order: violet, indigo, blue, green, yellow, orange, red; though the violet, by the mixture of the white light of the clouds, will appear faint, and incline to a purple.

Here it may be observed, that all the rays but the violet in the line SE will emerge from E in a greater angle than SEO made by the violet, and consequently will pass below the eye; and all the rays but the red in the line SF will emerge from F in a less angle than SFO made by the red, and consequently will pass above the eye; by which means only red will appear in the line SF, and only violet in the line SE.

And, since the lines OE, OF, may be situated anywhere in the above-mentioned conical surface; what is said of the drops and colours of these lines, is to be understood of the drops and colours throughout the whole superficies. Thus is the primary or inner bow formed.

Rainbow, Secondary, or Outer. As to the secondary, or fainter bow, usually surrounding the former, in alligning what drops would appear coloured, we excluded such as lines drawn from the eye, making angles a little greater than 42° 2', shall fall upon, but not such as should contain angles much greater.

For, if an indefinite number of such lines be drawn from the spectator's eye, some of which make angles of 50° 57', with the line of aspect, e. gr. OG; other angles, of 54° 7', e. gr. OH; those drops on which these lines fall must of necessity exhibit colours; particularly those of 50° 57'.

E. gr. The drop G will appear red; the line GO being the same with an effeetual ray; which, after two reflections, and two refractions, exhibits a red colour. Again, those drops which receive lines of 54° 7', e. gr. the drop H, will appear purple; the line OH being the same with an effeetual ray; which, after two reflections and two refractions, exhibits purple.

Now there being a sufficient number of these drops, it is evident there must be a second rainbow, formed after the like manner as the first.

Thus, according to sir Isaac Newton, in the least refrangible rays, the least angle at which a drop can send effeetual rays after two reflections, is found by computation to be 50° 57'; and in the most refrangible, the least angle is found 54° 7'.

Suppose, then, O the place of the eye, as before, and POG, POH, to be angles of 50° 57', and 54° 7'; and these angles to be turned about their common side OP; with their other sides OG, OH, they will describe the verges, or borders, of the rainbow CHDG.

For, if G, H be drops placed anywhere in the conical superficies described by OG, OH, and illuminated by the sun's rays, the angle SGO, being equal to the angle POG, or 50° 57', shall be the least angle in which the least refrangible rays can, after two reflections, emerge out of the drops; and, therefore, the least refrangible rays shall come most copiously to the eye from the drops in the line OG, and strike the fenestrae with the deepest red in that region.

And the angle SHT being equal to P OH, 54° 7', shall be the least angle in which the most refrangible rays, after two reflections, can emerge out of the drops; and, therefore, those rays shall come most copiously to the eye from the drops in the line OH, and strike the fenestrae with the deepest violet in that region.

And, by the same argument, the drops, between G and H, shall strike the fenestrae with the intermediate colours, in the order which their degrees of refrangibility requires; that is, in the progress from G to H, or from the inside of the bow to the outside, in this order: red, orange; yellow, green, blue, indigo, violet.

And since the lines OG, OH, may be situated anywhere in the conical superficies; what is said of the drops and colours in these lines is to be understood of the drops and colours every where in this superficies.

Thus are formed two bows, an interior and an exterior, by one reflection; and an exterior, fainter, by two; the light becoming weaker and weaker by every reflection.

Their colours will lie in a contrary order to one another; the first having the red without, and the purple within; and the second, the purple without, and red within; and so of the rest.

Rainbow, Artificial. This doctrine of the rainbow is confirmed by an easy experiment: for upon hanging up a glass globe, full of water, in the sun-shine, and viewing it in such a posture as that the rays, which come from the globe to the eye, may, with the sun's rays, include an angle either of 42°, or 50°; if, e. gr. the angle be about 42°, the spectator, supposing at O, will see a full red colour in that side of the globe opposite to the sun, as at F. And if that angle be made a little less, supposing by depring the globe to E, the other colours, yellow, green, and blue, will appear successively, in the same side of the globe, also exceedingly bright.

But if the angle be made about 50°, supposing by raising the globe to G, there will appear a red colour in that side of the globe towards the sun, though somewhat faint; and if the angle be made greater, supposing by raising the globe to H, this red will change successively to the other colours, yellow, green, and blue.

The same thing is observed in letting the globe revolve, and raising or depring the eye so as to make the angle of a just magnitude.
RAINBOW.

magnitude. Newton's Optics, part ii. prop. 9. prob. 4. p. 147; ed. 3.

The Dimension of the.—Descartes first determined its diameter by a tentative and indirect method; laying it down, that the magnitude of the bow depends on the degree of refraction of the fluid; and assuming the ratio of the fine of incidence to that of refraction to be in water as 2:50 to 187.

But Dr. Halley has since, in the Philosophical Transactions, N° 267, given a more direct method of determining the diameter of the rainbow from the ratio of refraction of the fluid being given; or, vice versa, the diameter of the rainbow being given, to determine the refractive power of the fluid.

The principles of Dr. Halley's construction for this purpose, illustrated and facilitated by Dr. Morgan, bishop of Ely, will be understood from the following view of them.

Let S N, s n, (Plate XVIII. Optics, fig. 5.) be two of the efficacious rays incident upon a drop of rain; these, when refracted to the same point F, and thence reflected to G, g, will have the parts within the drop on one side NF, n f, equal to those on the other side F G, f g, from the nature of the circle, and because the angles of incidence C F N, C F n, are equal to the angles of reflection C F G, C F g. And since the parts within the drop are equal and alike situated, they will be similarly situated with regard to the drop itself; and, consequently, as the incident rays S N, s n, are supposed to be parallel, the emergent rays G R, g r, will be also parallel. From C, the centre, draw the radii C N, C n, C F, then will C N F = C F N be the angle of refraction, and the small arc N is the nacent increment of the angle of incidence B C N; and as it measures the angle at the centre N C A, it is double of the angle at the circumference upon the same arc, viz. N F N, which is the nacent increment of the angle of refraction N F C. Further, let the ray S N (fig. 6.) enter the lower part of the drop, and be twice reflected within the drop at F and G; then is the ray N F equal to the ray F G, and the arc N F is the arc F G. Draw f g parallel to F G, and it will be the reflected part of some ray s n, whose obliquity to the drop makes it cross the ray N F in its refraction; then will the part n f = f g, and the arc n f = f g, and the small arc F f = G g. Therefore, 2 F f = (F f + G g = the arc F G = f g = N F − n f.) consequently N n = 3 F f, i.e. the nacent increment of the angle of incidence is equal to three times that of the angle of refraction. After a like manner it may be shown, that after three, four, five, &c. reflections, the increment of the angle of incidence will be four, five, six, &c. times greater than that of the angle of refraction. Hence, in order to find the angle of incidence of any efficacious ray, after any given number of reflections, we are to find an angle whose nacent increment in the same ratio to the increment of its corresponding angle of refraction, generated in the same time, as the given number of reflections (n) increased by unity has to unity; i.e. as n + 1 to 1. But these increments are as the tangents of the respective angles directly.

For A C : A B :: 1 : R; whence A C = I R + A B; and C F : B F :: n + 1 : 1; therefore C F = n + 1 × B F; or (putting n + 1 = m) C F = m × B F; and, on account of the right angle at F, A C' = C F' = B F', i.e. R R. A B' = m × B F' = A B' − B F'; and, consequently, B F = A B = \sqrt{\frac{m^2 R^2 - R^4}{m^2 R^4 - R^4}}. Hence, because in the first bow, the ray emerges after one reflection, we have n = 1, m = 2, m' = 4; and m − 1 = 3; therefore, \sqrt{3} R : \sqrt{11} − R R :: A B : B F; radius: cofine of the angle of incidence. In the second bow, where there are two reflections, m' − 1 = 8; whence \sqrt{8} R R = \sqrt{11} − R R :: A B : B F. In the third bow, after three reflections, m'' − 1 = 15; and \sqrt{15} R R = \sqrt{11} − R R :: A B

we have the angle of incidence 71° 26', and the angle of refraction 44° 47'; and, therefore, the angle AYS = 54° 7'. In the fame manner the fame angles are calculated after three or four reflections.

From the preceding problems we obtain the following re-
results, viz.

I. Rainbow, { Red 42° 2' } The fpектator's
II. Rainbow, { Red 50° 57 } back being turned
{ Violet 49° 34 } to the fun.

If the angle made by a ray, after three or four reflections, were required, and therefore the diameters of the third and fourth rainbow (which are scarcely ever seen, on account of the great diminution of the rays, by fo many repeated ref-
lections) they will be found,

III. Rainbow, { Red 41° 37' } The fpектator
{ Violet 37° 9 } being turned to-
{ Red 43° 52 } wards the fun.

IV. Rainbow, { Red 41° 37' } The fpектator
{ Violet 37° 9 } being turned to-
{ Red 43° 52 } wards the fun.

Dr. Morgan's Differtation upon the Rainbow, among
the notes upon Rohault's Syftem of Philosophy, part in
chap. xviii.

Hence, the breadth of the rainbows is eafily found: for
the greatest femi-diameter of the firft bow, i. e. from red to
being 42° 2', and the leaff, viz. from violet to violet,
40° 17', the breadth of the facria or bow, measured acros
from red to violet, will be 1° 45'; and the greatest diameter
of the fcond bow being 54° 7', and the leaff 50° 57', the
breadth of the facia will be 2° 10'. And hence the dif-
ference between the two will be found 8° 52'.

In thefe mafeures the fun is only eilleemed a point; where-
fore, as his diameter is really about 30', or 32', fo much
must be added to the breadth of each facia or bow, from
red to violet, and fo much must be subtracted from the
difference between them.

This will leave the breadth of the primary bow, 2° 15';
that of the fcondary bow, 3° 40'; and the interval be-
tween the bows, 8° 25'; which dimensions, deduced by cal-
culation, fir Ifaac Newton affures us from his own obser-
vations, agree very exactly with those found by actual
manifefation in the heavens. Optics, p. 153; ed. 5.

RAINBOW, Particular Phenomena of the. From this
tory of the rainbow, all the particular phenomena of it
are eafily deduced: hence we fee why the iris is always of
the fame breadth; becaufe the intermediate degrees of refran-
gr bill of the rays between red and violet, which are its
extreme colours, are always the fame. See Apparent Mag-
nitude.

Secondly, Why it is more diftinctly terminated on the
fide of the red than on that of the violet? there being no
efifics rays in the space adjoining to the red drops, i.e.
to the space between the bows, whence it terminates ab-
ruptly; whereas, in the space on the fide of the violet ones,
there are fome rays emitted to the eye, which, though too
feble to affect it strongly, yet have this effect, that they
fetten the violet edge infenfibly, so that it is difficult: to de-
termine precisely where it terminates.

Thirdly, Why the bow shifts its situation as the eye does;
and, as the popular phrase has it, flies from those who follow
it; and follows thofe that fly from it? the coloured drops being
dispoled under a certain angle about the axis of vision, which
RAINBOW.

is different in different places: whence also it follows, that every different spectator sees a different bow.

Fourthly, Why the bow is sometimes a larger portion of a circle, sometimes a less? its magnitude depending on the greater or less part of the surface of the cone, above the surface of the earth, at the time of its appearance; and that part being greater or less, as the line of aspect, or axis of vision, is more inclined or oblique to the surface of the earth; which inclination, or obliquity, is greater as the sun is higher: whence also, the higher the sun, always the less the rainbow.

Fifthly, Why the bow never appears when the sun is above a certain altitude? the surface of the cone, in which it should be seen, being lost in the ground, at a little distance from the eye, when the sun is above $42^\circ$ high.

Sixthly, Why the bow never appears greater than a semi-circle, on a plane? since be the sun ever so low, and even in the horizon, the centre of the bow is still in the line of aspect; which, in this case, runs along the earth, and is not at all raised above the surface.

Indeed, if the spectator be placed on a very considerable eminence, and the sun in the horizon, the line of aspect, wherein the centre of the bow is, will be notably raised above the horizon (considering the magnitude of the circle wherein the bow is to be a part). Nay, if the eminence be very high, and the rain near, it is possible the bow may be an entire circle.

Seventhly, How the bow may chance to appear inverted, i.e. the concave side be turned upwards? viz. a cloud happening to intercept the rays, and prevent their shining on the upper part of the arch: in which case, only the lower part appearing, the bow will seem as if turned upside down; which, probably, has been the case in several prodigies of this kind, related by authors.

Indeed the bow may appear inverted from another cause: for, if when the sun is $41^\circ 46'$ high, his rays fall upon the smooth surface of some spacious lake, in the middle of which is a spectator placed; and if, at the same time, there be no rain falling, in which the rays may be reflected from the lake, it will be the same as if the sun should shine below the horizon, and the line of view be extended upwards; thus the surface of the cone, wherein the coloured drops are to be placed, will be wholly above the surface of the earth.

But since the upper part will fall among the unbroken clouds, and only the lower part be found among the drops of rain, the arch will be inverted.

Eightly, Why the bow sometimes appears inclined? the accurate roundness of the bow depending on its great distance, which prevents us from judging of it exactly; if the rain, which exhibits it, chance to be much nearer, we shall see its irregularities; and if the wind, in that case, drive the rain so that the higher part be farther from the eye than the lower, the bow will appear inclined.

Ninthly, Why the legs of the rainbow sometimes appear unequally distant? if the rain terminate on the side of the spectator, in a plane so inclined to the line of aspect as to make an acute angle on the left hand, and an obtuse angle on the right, the surface of the cone, which determines what drops will appear, will fall upon them in such manner as that those on the left hand will appear farther from the eye than those on the right. For the line of aspect being perpendicular to the plane of the bow, if you suppose two rectangular triangles, a right and left, the cathetus of each to be the line of view, and the base of the semi-diameter of the bow, inclined as above; it is evident, that those angles of the triangles, next the eye, must always be the same (viz. $43^\circ$ in the inner bow), the bases of the right-hand triangle will, in this case, appear much longer than that of the left.

Dr. Langwith, in the Phil. Trans. No. 355, describes a remarkable rainbow, in which he observed several series of colours, which increased the bow to a breadth far exceeding what had been determined by calculation. The colours of the primary rainbow, he says, were, as usual; under this was an arch of green, and then alternately two arches of reddish-purple, and two of green, and under all a faint appearance of another arch of purple. The order of the colours was: 1. Red, orange, yellow, green, light blue, deep blue, and purple. 2. Light green, dark green, and purple. 3. Green and purple. 4. Green, and faint vanishing purple.

M. Bouger frequently saw a phenomenon of this kind, when he was upon the mountains of Peru, where the sky is often extremely serene. Similar appearances have been also observed by others. Dr. Pemberton has attempted to explain them by means of the Newtonian doctrine of fits of easy reflection and transmission: but he goes upon the supposition that the differently-coloured rays have their separate fits, on their arrival at the surface of any medium, without any regard to the thickness of it; whereas it is plain, that, in such a case, all kinds of rays are reflected or transmitted promiscuously. It is most probable that these colours are formed in very minute drops of water or vapour, intermingled with the larger drops, that their formation depends upon the same principles with the colours of thin plates, and that they are similar to those of several kinds of halos.

Dr. Pemberton himself observes, that it is most likely that these additional rings of colours are formed in the vapour of the cloud, which the air, being put in motion by the fall of the rain, may carry down along with the large drops. This, he says, may be the reason why these colours appear under the upper part of the bow only, this vapour not detecting very low. As a farther confirmation of this, these colours, he observes, are seen strongest when the rain falls from very black clouds, which cause the fiercest rains; by the fall of which the air will be most agitated. Phil. Trans. abr. vol. vii. p. 140. Friedley on Light and Colours, p. 593.

It has been a subject of controversy among biblical critics, whether the antediluvian atmosphere presented any such phenomenon as a rainbow. The occasion of this debate is a passage in Genesis, ch. ix. 12-17. Mr. Whitehurst, in his "Inquiry into the original State and Formation of the Earth," attempts to establish the probability that the antediluvian atmosphere was so uniformly temperate, as to be subject to no storms, tempests, or rain. The opinion is by no means probable, nor does the above-cited passage warrant any such conclusion. The rainbow was then made the sign or token of God's covenant with Noah, that no such calamity should again take place. $\frac{7}{8}$ denotes a sign or token, and in this sense it is used in the case of Cain, Gen. iv. 15. The mark set upon Cain was, as Shuckford conceives, a sign or token ($\frac{7}{8}$) given to him, that he should be preferred from the evil which he deprecated.

RAINBOW, Lunar. The moon sometimes also exhibits the phenomenon of an iris, or bow, by the refraction of her rays in the drops of rain in the night-time.

Aristotle says, he was the first that ever observed it; and adds, that it never happens, i.e. is never visible, but at the time of the full moon; her light, at other times, being too faint to affect the sight after two refractions, and one reflection.

The lunar iris has all the colours of the solar, very distinct and pleasant; only faint, in comparison of the other; both
both from the different intensity of the rays, and the different disposition of the medium.

In that mentioned, Philosophical Transactions, N° 331, Mr. Thoreby observes, the largeth of the arch was not so much less than that of the sun, as the different dimensions of their bodies, and their distance from the earth, should seem to require; but as the sun is a square, and the beauty of its colour, it was admirable. This continued about ten minutes before the interposition of a cloud hindered its observation.

Rainbow, Marine. The marine or sea-bow is a phenomenon sometimes observed in a much agitated sea; when the wind, sweeping part of the tops of the waves, carries them aloft, so that the sun’s rays, falling upon them, are refracted, &c., as in a common flower, and paint the colours of the bow.

F. Bourzes, in the Philosophical Transactions, observes, that the colours of the marine rainbow are less lively, less distinct, and of less duration, than those of the common bow; that there are scarce above two colours distinguishable, a dark yellow on the side next the sun, and a pale green on the opposite side.

But these bows exceed as to number, twenty or thirty being sometimes seen together; they appear at noon-day, and in a position opposite to that of the common bow, i.e. the concave side is turned upwards, as indeed it is necessary it should be, from what we have seen in accounting for the phenomena of the solar bow. A coloured bow is always to be seen in the scattered light of a jet, a broken cascade, and the like, when the sun and the spectator are in proper situations.

To this class of bows may be referred a kind of white or colourless rainbows, which Mentzelius, and others, affirm to have seen at noon-day. M. Mariotte, in his fourth Essay de Physique, says, these bows are formed in mists, as the others are in showers; and adds, that he has seen severally, both after fun-rising, and in the night.

The want of colours he attributes to the smallness of the vapours which compose the mist; but we should rather account for it from the exceeding tenuity of the little vessel of the vapour; which being, in effect, only little watery pellicles bated with air, the rays of light undergo but little refraction in passing out of air into them; too little to separate the differently-coloured rays, &c.

Hence, the rays are reflected from them, compounded as they came, that is, white.

Rohault mentions coloured rainbows on the graves, formed by the refractions of the sun’s rays in the morning dew. Trait. de Phy.

Rainbows have been also produced by the reflection of the sun from a river; and in the Philosophical Transactions, vol. I. p. 294., we have an account of a rainbow, which must have been formed by the exhalations from the city of London, when the sun had been set twenty minutes, and consequently the centre of the bow was above the horizon. The colours were the same as in the common rainbow, but fainter.

The best way of forming a resemblance of a rainbow is to fatten a number of small glass balls, or a number of small glass bubbles full of water, upon a dark board, and to present the board thus furnished to the sun at a proper inclination, which experience easily finds, whilst you turn your back to the sun, and look at the board.

Rajgra, a town of Hindustan, in Dowlatabad; 18 miles W.N.W. of Koudur. Alto, a town of Bengal; 65 miles N. of Dacca.

RAJOUR, a town of Hindostan, in Lahore; 36 miles N.W. of Jumna.

RAIOWLY, a town of Hindostan, in Bahar; 30 miles S. of Bahar.

Rajpoortana, a country of the Rajpoorts, generally denoting Agimere (which see), and the original country of the founder of the Mahratta state, whose rulers, about half a century ago, aspired at universal empire in Hindostan; but they have been reduced to their present low state, by the depredations of Mahratta detachments, which, being composed of horse, and accustomed to separate into small parties, have, by their defultory movements, at once spread defoliation, and eluded the attacks of the inhabitants. This is the fact with regard to the open parts of Rajpoortana; the mountainous parts remaining free from their incursions.

Rajpoortana was divided into three great principalities, under the names of Oudipour, Joonpur, and Ambeer (or Amere), now better known by that of Jyepour, or Jyena.

In Achar’s division of the empire, these principalities were classed as belonging to the tributary of Agimere, sometimes called Marwar. It is not easy to assign the precise limits and dimensions of these principalities, which occupy the space between the western confines of Agra and the north-east of Guzerat, and between the sandy desert (or Regillian) and Malwa; that is, an extent of 320 British miles from N.E. to S.W., and 200 broad in the widest part. Jyepour or Jyepour lies to the N.E., Oudipour to the S.W., and Joonpur to the N.W., bordering angularly on the other two. Pere Wendell’s MS., cited by Rennell, states the revenues of Oudipour at 10 lacks of rupees, Marwar at 40, and Jyepour at about 60, per annum, in the year 1779. The whole revenue of the fobah of Agimere, in the time of Achar, appears to have been only about 75 lacks. Aurungzede is said to have doubling the land-tax on the Rajpoorts, and accordingly in Mr. Fraher’s account, Agimere is stated at 163 lacks of rupees. The two former, viz. Oudipour and Marwar, are very mountainous, with a sandy soil in the valleys; the latter is the most fertile, and was, about the middle of the last century, in a high state of improvement, under the government of the celebrated rajah Jyefing, or Jeffing, who founded the new capital of Jyepour, whence the name of the province was changed to that of the capital. Jyepour was a place of great wealth and commerce in 1779, being the entrepot of the principal part of the goods that are brought from every quarter of India. The rajah built an observatory in his capital; but the confusions that have so long prevailed in this province, must have greatly reduced the wealth and importance of the capital. Sindia, as Rennell informs us, received the tribute of all the three Rajpoort provinces, and converted it to his use, and he also made confederate conquests in them, particularly in Jyepour.

In early times the whole Rajpoortana probably constituted one entire kingdom, or empire, under the name or prince of Oudipour, the head of the Rajpoort states; the antiquity of whose house may be inferred from the name Rhane.
RAI

Rhanne appearing in Ptolemy, nearly in its proper position, as a province. See OUDIPOUR.

The province of Agimere in general (see AGIMERE) has ever been the country of the Rajpoots; that is, the warrior tribe among the Hindus, and which are noticed in Arrian and Diodorus; and Thevoren, or Oudipour, (considered by Rennell as synonymous,) is, in his opinion, reckoned the first among the Rajpoot states. See CHITEIOTE.) From the Ayin Acaaree we derive some new ideas respecting the division of the foubah of Agimere. It confided at that time of three grand divisions, Marwar, Meywar, and Hadowry (or Nagore); and these contained seven circars or subdivisions, Agimere, Chitera, Rantappour, Joutppour, Sirouly, Nagore, and Beykeener (or Bicaner). Marwar, as including the circar and country of Agimere, has become almost synonymous with Agimere, in common acceptation. The extent of this province, as given by the same book, is 168 coffes, or about 320 British miles, from E. to W.; and 150 cottes, or 285 British miles, from N. to S. Such is the province of the Rajpoots. From the indulgence granted to this tribe throughout India, viz. that of feeding on goats' flesh, it may be inferred, says Rennell, that the custom originated in this mountainous country. The grain cultivated there is chiefly of the dry kind. The taxes assessed in the time of Achar, to no more than a seventh or eighth of the produce of the harvest. Rennell's Memoir.

RAJPOOTS, the inhabitants of Raipootana; which see. They were not confined entirely to the foubah of Agimere; as some inferior tribes of them are settled in Bundelcund, and in Gurry-Mundella. Others, according to Thevenot, are settled in Moultan; and indeed he represents Moultn as the original country of the Kuttres, from whom the Rajpoots sprung.

The Kuttres or Catries, who formed a particular sect of Hindus at Moultan, were the Catheri of Diadorus, and the Catheii of Arrian, with whom Alexander carried on war, on the borders of the Malli. The Rajpoots are ordinarily divided into two tribes or claffes, viz. those of Rathore, and Chohan or Sefodya. Marvar, or the N.W. division of Agimere, is the proper country of the former; and Meywar, or Oudipour, of the latter. The Rathore tribe were originally the most numerous of the two; and it has been said by colonel Dow, among others, that the Mahratta chiefs had their origin from the Rathore tribe; and in proof of this it has been alleged, that the etymology of the name Mahratta has been deduced from Rathore, prefixing to it "maha," or great. (See MAHRATTA.) The Rajpoots are represented by Thevenot as having spread from Moultn, their proper country, over all the Indies. Diodorus Siculo distinguishes them by the custom of their women burning themselves alive, on the funeral piles of their husbands; and indeed a custom among them, as well as some other Hindoos, at this day, Rennell.

Vol. XXIX.
cient to overcome the weight, or resistance, of the object to which the machinery is applied.

**Raising-Pieces, or Raisen-pieces, in Architecture,** are pieces that lie under the beams, and over the posts or pungeons: those lying on the brick-work are called platbands.

**RAISINS,** grapes prepared by drying them in the sun, or in the air; to fit them for keeping, and for some medicinal purposes.

Of these there are various kinds: as, raisins of Damascus, thus called from the capital city of Syria, in the neighborhood of which they are cultivated. They are much used in the composition of pithans, together with jujubes and dates; they are brought flat, and seeded, of the size of the thumb; whence it is easy judging of the extraordinary bulk of the grape, when fresh. Travellers tell us of bunches weighing twenty-five pounds. Their taste is sublimate and disagreeable.

Raisins of the sun are a kind of raisins brought from Spain, of a reddish or blue-colour, seeded, and very agreeable to eat.

There are various other sorts, denominated either from the place where they grow, or the kind of grape, &c. as raisins of Calabria, Mufcadine raisins, &c.

The finest and best raisins are those called in some places Damascene and jube raisins. These are the fruit of the _Vitis Damascena_, and are distinguishable from the others by their larger, and numerous berries, and figure; they are flat, and wrinkled on the surface; soft and juicy within, near an inch long, and semipellucid, when held against a good light; they have a sweet, agreeable, and vinous taste; and when fresh, and growing on the bunch, are of the size and shape of the large olive.

The common raisins are the fruit of several species of grape, which are better or worse, according as they have been more or less carefully cured. The raisins of the sun, or jar-raisins, so called, because they are imported in jars, are all dried by the heat of the sun; and these are the sorts used in medicine.

The common way for drying grapes for raisins is to tie two or three bunches of them firmly together, while yet on the vine, and dip them into a hot liquornium of wood-sap, with a little olive oil in it. This disperses them to shrink and wrinkle; and after this they are left on the vine three or four days, separated on sticks in an horizontal situation, and then dried in the sun at leisure, after being cut from the tree. Some raisins are dried by the heat of an oven; and the difference between these and such as are dried in the sun, is obvious; the latter are sweet and pleasant, but the former have a latent acidity with the sweetness, that renders them much less agreeable. See Currants.

All the kinds of raisins have much of the same virtues; they are nutritious and balsamic, but they are very subject to fermentation with juices of any kind; and hence, when eaten immoderately, they often bring on colics. They are allowed to be attenuant, and are given in cafés where the humours are too thick and viscid, and they are said to be very good in nephritic complaints; they are, however, too familiar in our foods, to be much regarded at present as a medicine. They are an ingredient, indeed, in our pectoral decoctions, and in some other medicines of that intention; in which cases, as also in others where shrivelling is not required of them, they should have the stones carefully taken out. They are used in some compositions rather with an intent of taking off the nauseous tallow of other ingredients, and for obtunding their acrimony, than of doing any extraordinary service themselves.

**RAISIN-BRANDY,** a name given by our distillers to a very clean and pure spirit, procured from raisins fermented only with water. Thus treated, they yield a spirit, scarce at all distinguishable from some of the wine-spirits; for there are as many kinds of wine-spirits as there are of grapes. The sooner the operation of distilling is performed in this case, the nearer will be the resemblance of the wine-spirit; that is, there will be most of this flavour in the spirit, when as much as can be of the oil is thrown up with a gelling heat.

The distillers are very fond of the wine-spirit, with which they hide and disguise the taste of their nauseous malt, and other spirits; and in defect of that spirit, this of raisins, made in this course manner, will go almost as far. It is indeed surprising how extensive the use of these flavouring spirits is, ten gallons of raisin-spirit, or somewhat less of the wine-spirit, being often sufficient for a whole pipe of malt-spirit, to take off its native flavour, and give it an agreeable vivacity. It is no wonder, therefore, that the distillers, and ordinary rectifiers, are so fond of this, as it is a good cloak for their defects, and the imperfection of their processes.

When raisin-brandy is intended for common use, the fire should be kept flower and more regular in the distillation; and the spirit, though it hath less of the high flavour of the grape, will be more pleasant and more pure.

**RAISIN-WINE. See WINE.**

**RAITAPOUR,** in _Rural Economy_, a term used to signify the procés or operation of distilling the sap of vegetables, by exposure to moisture, or the influence of the atmosphere. It is mostly applied to hemp, flax, or other similar substances, and sometimes to hay, when it has been much exposed to alternations of wet and dry weather.

When the process is performed by means of water, as is mostly the case with hemp, frequently but not always with flax, and occasionally with other articles of the same nature, it is usually denominated water-raiting, and the article is said to be water-raited; but where it is effectuated by exposure to the air, upon the ground, when spread out, it is generally called ground-raiting, and the substance is said to be ground-raited. In the performance of these operations or procéses with hemp, flax, and such like substances, there is great nicety and attention required to see that they are carried to a sufficient length, without going too far, so as to injure the textures of the substances in their cortical parts. This may probably be accomplished with the greatest certainty by the frequent examination of the materials themselves; keeping them perfectly under the water in the former case, and frequently turned with new surfaces to the atmosphere in the latter, never having the granfy surface on which they are spread out of too great a length. The effects of heavy rains, when long continued, must likewise be carefully attended to in this latter instance. See Flax, Hemp, and Water-raiting.

**RAITENBURG,** in _Geography_, a town of Hindooistan, in the circar of Rajamundry; 12 miles N. of Rajamundry.

**RAITCH,** in _Rural Economy_, a term signifying a line or lift of white, down the face of a horse. It is a very common mark in the faces of horses.

**RAITENBACH,** in _Geography_, a town of Germany, in the principality of Cumbach; 8 miles E.N.E. of Wonfiedel. Also, a town of Bavaria, in the bishopric of Achishläd; 8 miles N. of Aichshaldt.

**RAITENBURG,** a town of the duchy of Carniola; 3 miles N. of Rudolfswehrc.

**RAITING, GROUND,** in _Rural Economy_, that method of raiting or accomplishing the separation of the barks or coverings of the stems of flax, hemp, and other similar plants,
by means of spreading them out in a thin manner upon close graily surfaces, instead of putting them into ponds or pools of stagnant water, in order that they may be exposed to the atmosphere. It is occasionally employed for flax and other small italked plants, but seldom or never for hemp and those which have large ones. It is a practice which stands in need of considerable attention and management. See RAKE.

RAJAPURA, in Geography, a town of Mocam-pour; 18 miles S. of Bargaoo.

RAIVATA, in Hindoo Mythological History, one of the faints or gods included in the denomination of Menus. Raivata is said to have been the son of Agni, the regent of fire, also called Paraka, (which fee), and Menu.

RAJYA, in Geography, a town of Hindooftan, in Bah- bar; 20 miles E.S.E. of Bahar.

RAKAPORAH, a town of Hindooftan, in the circar of Juhipour; 10 miles N.E. of Deycpour.

RAKAS, a town of Transylvania, on the Allaut; 16 miles N.W. of Cronfadt.

RAKE, in Agriculture, a tool of the toothed kind, made use of for many purpofes of husbandry, as for collecting togethcr hay, corn, flubble, roots, leaves, and other fimilar forts of materials. It is a very useful and convenient kind of tool in all fimilar intentions. There are many defcriptions of this fort of implement.

RAKE, Bean-Stubble, a tool of the rake kind, contructed for the purpofe of clearing bean-stubbles. It is employed on some farms in Eife, as by Mr. Ketcher, at Burnham, where it is found to be well-adapted to this ufe, and to do its work in a perfect manner. The head, which is seven feet eight inches in length, is formed with a veiy flight curve, having teeth fet in it in a clofe manner, which are one foot and a half in length, bending or curving a little forwards at the points. It is attached by a frame to the axle of the wheels, which is three feet two inches long; and the wheels are two feet fix inches in their diameter. The hooks and shafts for the horfe are four feet in length. This is a very fimple conftruction of this nature, and one which is capable of eafy application. The teeth fhould be made strong, whether they are of wood or iron. This is an implement which wants to be better known in other districts.

RAKE, Corn, a large strong rake, made ufe of in different districts for bringing together the mown grain crops. It is sometimes conftructed with wooden teeth, but a better mode is to have them of iron, being a little bent forward, having the length of seven or eight inches. As it requires much exertion to perform the work with them, they fhould always be made as light as possible, fo as to have fufficient power to perform the work. It has been flated by Mr. Somerville, in his Agricultural Survey of the Diilritc of Earl Lothian, that though the common hay-rake is moftly ufed there, a different kind for grain has been partially tried, and found to answer the purpofe much better. In this, the length of the head is from ten to fifteen feet, the handle about seven feet, with a piece of wood acrofs the end of it, by which it is drawn by two men. The teeth are of wood or iron; the laft are the bell, as well as the mofi durable, and are a little bent forward at the point, which gives them the power of retaining and carrying the ears along with them, much better than they would otherwise do. To make clean work, efpecially if the ridges are gathered, the field is raked acrofs; in that way, every thing is taken up. But when it is preferred to draw the rake in the direftion of the ridges, it may be considerably improved, by cutting the head into two or three lengths, and joining them with hinges, which will allow it to bend and accommodate itfelf to the curvation of the ridges. The advantage of this kind of rake has been found considerable, even in cafes where every poftible attention has been paid to the cutting of the crop; but it frequently happens, that, owing to the dampness, greennefs of the straw, or a foul graily bottom, it is neceffary to leave the crop unbound for a day or two, during which, if it be overtaken by a high wind, much of it will be scattered and loft, unless confiderable pains are taken to gather it by hand-raeking, or otherwife. Where the long rake is ufed for that purpofe, the expence will in no infance, he thinks, exceed four-pence tlerling per acre. An experiment made on a field of 30 acres, will convey some idea of the benefit that may be derived from the ufe of that implement. The field was in barley, and the raking, when threshed, yielded

Carrting from the field, racking, &c. | 0 2 6
Threshing | 0 7 6

Total expence 1 1 10

Which deducted from 14l. 5s., leaves a profit of 13l. 3s. 2d. Tlerling. It is neceffary to obferve, that about ten acres of the field were left unbound, and a good deal disordered by a high wind; but as confiderable pains were taken in the binding, the proportion obtained from thefe ten acres did not greatly exceed what was got from the rest of the field, the whole of which was cut with a great deal of care.

But though this mode of working the rake affords confiderable profit and advantage, they would be a great deal more, by having recourfe to horfes in the draught of them. One horfe in each would do as much labour as feveral men, in a given time; and by having shafts and low wheels fixed to the tool, it could be readily adapted to this method of being wrought.

RAKE, Couching, a large fort of strong horfe-rake, with long round toys or teeth, crooked or bent forward in a gentle manner, and placed about two inches diftant from each other; and a fmall beam in the middle, with fide pieces, and an apparatus for attaching the horfe to it. It is found very useful in bringing together the roots of cough, and other weeds, in order to their being burnt, or carried off the land, and in other ways defroyed. See COUCH-Rake, QUICH-Rake, and RAKE-Twitch.

RAKE, Dew, a fort of large rake, or hand drag, fo named from being ufed before the dew is off the ground, or other fort of harvet work can be begun. It is a powerful convenient fort of implement for harvet work.

RAKE, Garden, a well known fort of tool for raking the ground, as well as for putting in feeds, &c. In order to fuit every kind of gardening work with rakes, there fhould be three or four different fizes, from about fix to eighteen inches long in the head, having handles from fix to eight feet in length, and the heads toothed with iron teeth: two or three inches long, being placed from one to two inches afunder, according to their refpective fizes. The firft or largeft rake fhould have the head about fifteen to eighteen inches long, the teeth three inches, and placed two inches afunder, which is proper for raking flubbm or rough dug ground, and for putting in large kinds of feeds, raking off large weeds after hoeing, and many other pur-
poles in large gardens. The next size should have the head twelve inches long, the teeth three inches, being placed one inch and half afender, which is proper for all common raking in ordinary light ground, and for raking in most kinds of small seeds, as well as other purposes. A third fort of small rake should have the head about nine inches long, the teeth two and a half, being placed one inch afunder; proper for fine-raking beds, borders, &c. and raking in some particular fine seeds; as well as between rows, &c. of certain plants occasionally, where larger rakes cannot be introduced. And the smallest fort should have the head six inches long, the teeth two and a half, and placed one inch afunder; being very useful for raking between small plants in beds and borders, and other small parts, where the plants stand closer, as well as several other purposes of that kind.

It may be noticed, that all these forts of rakes are constructed both with wooden heads and iron teeth, and with the heads and teeth wholly of iron in both; of which the teeth are generally flattened, the back edge rounded off, and narrowing gradually to the point; the other straight, and plain on the heads edgewise across, with the back edge outward, and with the points all inclining very moderately inward, in a regular manner: the wooden-headed rakes having each end of the head hooped with a thin flat iron ring, to secure it from splitting. It is very seldom that wooden teeth are employed in this way, or for these uses.

Those of the first fort are generally the lightest and cheapest, being proper for any kind of garden raking; but the latter, or iron-headed rakes, when made neat and as light as possible, with the teeth well set, in a proper position, and firmly fastened, are equally proper, and in some cases preferable, as in some wettish or moist soils, as not being liable to clog so much as wooden rakes, and at the same time more durable. They are, however, more proper for middling and small rakes than for large ones; as, in strong raking, the teeth are more liable to get loose than in the wooden-headed rakes.

Both the forts, in their different sizes, are sold at the principal ironmongers' shops, both with and without handles.

And rakes having the heads, teeth, and handles, wholly of wood, may sometimes be used for particular purposes; such as raking in light kinds of kitchen-garden seeds in light ground, and taking off large hood-up weeds in wide clear spaces, raking up swaths of mowed short grass before the sweepers, also fallen leaves of trees in autumn, and clippings of hedges, &c. as well as several other uses about the pleasure-garden.

Rake, Hay, a well-known tool, with short teeth and a long handle, made use of in making hay. It is usually made of willow, or some other familiar wood, in order that it may be light and handy. The teeth should not be too long, as, when that is the case, they are apt to hang and pull among the stubs of the grass in raking with them, and thereby retard the operation, as well as cause much fatigue to the labourer.

Different improvements have been made on this implement. A late useful alteration is the making the teeth to screw into the head, and fallen with screw nuts, by which the inconvenience of their dropping out in dry fields is obviated. It has been observed, that with the spring-toothed rake, the operator is capable of performing much more work than by the common one. They are likewise capable of being conveniently made use of both for hay and corn. They were originally made and sold by Mr. Cort, of Leicester.

Another improvement is mentioned in Young's Agricultural Report of Norfolk, which is the addition of wheels. It is flated, that the "hand wheel-rake" of Fleg is an excellent implement for both hay and corn: it is to answer the purpose of the common hay-rake, and is about four feet long in the rake; and the two wheels, of nine inches diameter, so fixed, that the teeth are kept in any posture, at the will of the holder.

In some parts of Lancashire, they make use of a large horse-rake for collecting the hay together, and raking it up from the ground, which is found to be highly convenient and beneficial; as one horse, in one of these rakes, will perform as much labour as a great number of men, in a certain space of time; and besides the expedition, the work is considerably better done, in consequence of the greater weight of the implement.

The head of the rake has something of a large easy half circular form, into which two strong pieces of wood are fastened, which constitute the shafts for the horse. There are two low wheels behind, and the head has long teeth, curving a little forward, fixed into it at two or three inches from one another. The teeth may be made either of wood or iron, and should have considerable strength. The whole has no very great weight, though it must obviously be considerably heavier than the common rake: which is found of much advantage in its working, as has been hinted at above.

Rake, Horse, an implement used in Norfolk and Suffolk, on the large and middling-sized farms, and, from its great utility, extending itself into other districts. It is employed for barley and out crops, being drawn by a horse. And it has been slated by Mr. Young, that one man and a horse, driven by means of a line or rein, are capable of clearing from twenty to thirty acres, in a moderate day's work; the grain being deposited in regular rows or lines across the field, by simply lifting up the tool, and dropping it from the teeth, without the horse being lopped. It costs from four to five pounds.

Figures of it may be seen in the above Agricultural Reports. Horses have now been employed for working other forts of rakes, and found of great advantage, as has been already seen.

Rake, Horse Stubble, a large heavy kind of horse-rake, having strong iron teeth, fourteen or fifteen inches in length, placed at five or six inches from each other, and a beam four inches square, and eight or ten feet in length. In drawing it, two horses are mostly made use of, by which it is capable of clearing a considerable quantity of stubble in a short time. Tools of this fort are highly useful on corn farms, for collecting this useful material, and should be much more frequently employed than they are at present.

Rake, Touch, a large horse-rake, employed in certain cafes for clearing lands from the roots of couch, twitch, or quitch-grass, as well as those of other forts. It is constructed in different ways, as with one or two rows of teeth; but the latter is probably the best method, as by placing one row opposite the intervals of the other, it must be rendered a very efficient tool.

Rake of a Ship, is so much over her hull as over hangs at both ends of her keel.

That part of it which was before, is called the rake forward; and that part which is at the setting on of the stern-poll, is called her rake-off, or afterward.

When a ship hath but a small rake forward-on, but is built with her stern too straight up, she is called bluff-headed.

Rake of the Rudder, is the hindermost part of it.

Rake, among Hunters. See Rag.

Rake, in the Mange. A horse rakes, when being shoul-der-plaid, or having strained his fore-quarter, he goes so lame, that he drags one of his fore-legs in a semicircle; which
RAK

which is more apparent when he trots, than when he
paces.

RAKE, or Vein, in Geology, the most common repository of
metallic ores. These veins intersect mountains nearly
vertically, or more or less inclined from the perpendicular.
They are filled with ores, intermixed with the peculiar
minerals accompanying each kind of metal. They vary
from a few inches to some feet or yards in width, and ex-
tend to a very considerable depth and distance. The upper
side of the vein is provincially called the banger, and the
lower side the ledger; and the inclination from the perpendicular
is called the hade of the vein. For a particular ac-
tount of the structure and formation of veins, see Veins,
Metallic.

RAKEL, in Geography, a town of Dobruzzi Tartary,
on the Danube; 15 miles W. of Tâkki.

RAKESBURG, or Raikelsburg, a town of the duchy
of Stiftia, situated on an island in the Mucker; the inhabitants
of which carry on a considerable trade with Hungary and
Croatia; 36 miles S.E. of Gratz. N. lat. 46° 45'.
E. long. 15° 26'.

RAKING signifies floping or winding, as when a wall
is not built up right or straight.

RAKING, in Agriculture, the operation of performing
work with a rake. It is a fort of work that requires little
art or trouble in its execution; but whether performed with
the common or horse-rakes, it should always be done in an
effectual manner. In the business of hay-making, clean
raking not only affords a neatness in the appearance, but,
over a great extent of surface, a considerable faving of hay.
See HAY-Making.

In raking hay lands, where horses are employed, some
degree of care is necessary in directing the work, and driving
the animals, in order that no inconvenience of delay may be
experienced, and that every part of the land may be gone
over in the most regular manner. Small boys may serve to
direct the horses by riding upon them, and some faving be
made in that way.

In raking cut corn crops with horse-rakes, especially
those of oats and barley, it is sometimes the bell method to
proceed in a cross direction of the ridges, drawing up the
produce into long rows at suitable distances; the horses
being driven by the men, who know the management of the
handles of the rakes, by means of whip reins brought from
the horses to the floats of the implements. It seldom hap-
pens that so good work can be made in going the length-
ways of the lands, particularly where they are much
rounded, and of a small size in breadth, as the tools will
not fit well to their rounded form, unless where they are
constructed in separate parts in their heads, so as to admit
of motion by means of joints. In this mode of raking, the
corn may sometimes be readily tied up into sheaves.

But in the raking of flubbles, it is more useful to pass in
the direction of the ridges, though the contrary method is
not unfrequently had recourse to. In those cafes, as well
as in the others, the flarry grains or flubbles are always
brought together into lines or rows, in order to be more
readily taken up by the carts either bound or unbound.

In the raking of the roots of weeds together upon lands,
it is constantly the best practice to perform the work in
both directions; as, by such means, the whole of them may
be laid hold of in a more complete and effectual manner than
could otherwise be done. See Rake.

RAKING, in Gardening, a necessary operation in the gar-
den, to break the surface of the soil small, and render it
fine for the reception of particular sorts of small feeds and
plants, previous to sowing and planting, as well as to render
it neat and even to the eye. It is also employed in raking in
feeds, as being an expeditious mode of covering them in.
In all kinds of small feeds, or hardy plants, the ground
being dug, &c. and the surface remaining rough after the
spade, the feed is sown, and then raked in with an even
hand, once or twice in a place, as a back and a fore stroke,
or more as may be necessary.

And this operation is useful also among growing plants,
that stand distant enough to admit the rake, particularly
where the surface is inclinable to bind, or where numerous
small feed-weeds appear, as it loosens the soil, and retards
the growth of the weeds, and promotes the growth of the
young plants. It is also good culture at particular seasons,
to ammoy flags, especially in kitchen-gardens, to rake be-
tween the rows of small plants in autumn and winter, &c.
The raking of the beds, borders, and other compartments of
pleasure-grounds, now and then, smooth and even, like-
wise gives an air of culture and neatness to the whole.

It may be observed, that this sort of work should gen-
erally be performed in dry weather, and when the ground
is also moderately dry; as when done in rainy weather, or
when the ground is very moist and cloggy, the surface is
apt to cake and bind hard. This should be well attended
in to fowling feeds. Rough dug ground does not rake well,
when it is become very dry at top, especially if it was dug
wet, and suffered to lie till the clods have become very dry
and hard, in which case it will not rake well, until mellow-
or pulverized by a shower of rain. But common
light garden ground generally rakes best when fresh dug,
perhaps the same day, or day after at the fartheft, before
dried too much by the fun and wind, or rendered wet by
rain, &c. The operation should, however, be performed
when the ground is in such order as the clods will readily
break and fall to pieces under the rake, without clogging
much to it, or the mould become even without running into
jumps.

RAKING of a Horse, is the drawing his ordure with
the hand out of the fundament, when he is coltive, and cannot
dung. In order to do this, the hand must be anointed with
fallad-oil, or butter.

RAKING a Ship, is the act of cannonading a ship on
the stern or head, so that the guns shall four the whole length
of her decks, which is one of the most dangerous incidents
that can happen in a naval action, so much fo, that the men
are ordered to lie down at their quarters. This is frequently
called raking fore and aft, being the fame with what is
called enfilading by engineers. See ENFILEADE.

RAKING-Knees. See Knees.

RAKING-Table, or Raked Table, among Architects, a mem-
ber hollowed in the square of a pedestal, or elsewhere. See
CAVETTO, and SCOTIA.

RAKOKIE, in Geography. See RACH-KOKE.

RAKONITZ, or RAKOWNITZ, a town of Bohemia,
and capital of a circle of the same name, which is moun-
tainous and covered with forests, but fertile in corn, and
affording some excellent horses. It was made a royal town
in 1385. It is celebrated for its beer, which is the prin-
cipal article of its commerce; 22 miles W. of Prague. N.
lat. 50° 5'. E. long. 13° 57'.

RAKORA, a town of European Turkey, in Bulgaria;
40 miles S.S.E. of Viddin.

RAKOW, or RACOW, a town of Austrian Poland, in
the palatinate of Sandomir, formerly populous; the Soci-
arians had a college and printing-house here, but were ex-
pelled in 1643; 40 miles W. of Sandomir. See RACOW.

RAKOWENA, a harbour on the coast of Kamchi-
chatka, in Avatka bay, three miles long, and one and a
half
half broad, with water from thirteen to three fathoms, and a bar at its entrance; it runs at first in a south-eaft and afterwards in an easterly direction; three miles S. of St. Peter and St. Paul.

RAKSHA, in Hindo Mythology, a species of malignant demon, of whom great use is made in their epic machinery and popular tales. They are of various shapes and colours, and supposed to be animated by the souls of bad men of earlier existence, receiving punishment in the forms as enemies to the gods, and obstructers of their beneficent intentions towards mankind. Another class of these evil genii comprehends those called Yaksha. Rakshas and Yakshas are the plurals, and Rakshani and Yakshini the feminine; for these evil doings are not confined to sexes. Ravana, the giant king of Lanka, or Ceylon, who opposed Rama, aided by the gods in the invasion of his kingdom, is sometimes called the lord of Rakshas. See RAVANA.

RAKULSKOI, in Geography, a town of Russia, in the province of Uling, on the Dona; 20 miles N. of Krasno-,borsk.

RALEIGH, Sir Walter, in Biography, a distinguished character in the reigns of queen Elizabeth and James I., was second son of a gentleman of an ancient family in Devonshire. Few names, says Sir Walter’s biographer, Mr. Cawley, vary so much in the manner of writing it. By Sir Robert Naunton and Lord Bacon it is written Raleagh; in some old deeds the orthography is Ral or Raiga; while King James, Hooker, and other respectable writers, adopt the mode of spelling which is still common in this country, viz. Ralegh; but the original letters of Sir Walter himself, wherever the signature is preferred, have Ralegh, and on that account we choose to adopt it in this work. Sir Walter, of whom we are treating, was born at a farm called Hayes, in that part of Devonshire that borders on the sea, in the year 1552. By his mother he was related to those famous knights, Sir John, Sir Humphrey, and Sir Adrian Gilbert. After he had received the usual school education, he was sent to Oriel college, Oxford, where he distinguished himself by a proficiency in learning far beyond his age; but the active disposition and martial ardour with which he was endowed, soon put an end to his learned career. About the year 1569, he, in company with many young gentlemen of the best families in the country, went into France, as well to instruct themselves in the art of warfare, as to assist the Protestant in that kingdom, who were then grievously oppressed. In this school he was employed five or six years, but by what means he escaped the horrible massacre of Paris, and the provinces, on the famous St. Bartholomew’s day, we have no knowledge. He returned to England in 1575, and it should seem he immediately became a resident in the Middle Temple, whence a commendatory poem of his, prefixed to a work of George Garton’s, is dated in 1576. That he was not a student in the law, at this time, he has himself declared, and he shortly after passed into the Netherlands, where he served some time against the Spaniards. In this, and other transactions of the same kind, he followed the fashion of the times. France and the Netherlands were in those days the schools of Mars; to which all were obliged to resort who meant to pursue the fortune of arms. Many young men returned to their native country ruined in their fortunes, their constitution, and morals; but Raleigh had made a good use of his time, gained a large flock of useful knowledge, and was so completely polished in his manner of address, that he was now considered as one of the best bred and most accomplished gentlemen in England.

On his return in 1578, he found his half-brother, Sir Humphrey Gilbert, engaged in a design of making diffic.

veies in North America, for which he had obtained a patent, and for the furtherance of which he had procured the affitance of many friends. Raleigh was delighted with the design, and embarked in it cordially. This project proved very unfortunate to the adventurers, but it gave young Raleigh an introduction to the sea service, in which he afterwards so much distinguished himself. From this unlucky adventure, Mr. Raleigh arrived safe in England in the spring of the year 1579, and very soon after he appears to have offered his services to the queen to go to Ireland, to the inhabitants of which, pope Gregory VIII. and the Spaniards had sent men, money, and other assistance, to enable them to take arms against the established government. He obtained a captain’s commission, and served in Munster under the earl of Ormond. In this petty warfare he displayed so much good conduct, vigour, and courage, that he was afterwards made governor of Cork; and as a reward for his services, he received from the crown the grant of a considerable estate in Ireland. A misunderstanding with the lord-deputy Grey put a stop to his further rite in the army; he returned to England, and was quickly introduced to the queen’s notice, and by his own merits attained a large share in her favour. As he was forward to distinguish himself in all public services, so on the return of the duke of Anjou into the Netherlands, he was one of those who accompanied him out of England, by the express command of queen Elizabeth, and on his coming to England in 1582, he brought over the prince of Orange’s letters to her majesty. Some months after this he resided at court, and was honoured with the favour and protection even of contending factions, who were proud of showing the true judgment which they had of real merit, by becoming patrons to Raleigh. In 1583 he was concerned in his brother Gilbert’s second attempt, and though he did not venture in person, yet he built a new ship, called the bark Raleigh, and furnished it completely for the voyage; “the unsuccessful end of which,” says Campbell, “it seemed to predict, by its untimely return in 1½ or 2 years to Plymouth, through a contagious distemper which feized on the ship’s crew.”

While at home Raleigh was not negligent of pushing his fortune as a courtier. “He had a good person and address, made an elegant appearance, and put on that air of gallantry which was so meritorious in the eyes of Elizabeth. It is said, that he was once attending the queen in a walk, when she came to a spot, that by its mere obtrusion her course; he immediately took off his rich cloak, and spread it on the ground for her to walk on. Pleaded with this attention, it is observed, that the favourite of a clock obtained for him many a good suit.” The enterprising spirit of Raleigh was shown in the year 1584, in a scheme which he formed of making discoveries and settlements in those parts of North America which had not been subjected to any European power. His interest at court, and his ability in flattering and getting forth his plans to the best advantage, obtained for him an extensive patent for executing his purpose; and, in consequence, with the help of a society of his friends, he fitted out ships under the command of captains Amadas and Barlow, which failed from Plymouth in that year, and took possession of an island near the mouth of Albemarle river, in what is now called North Carolina. From the terms of the patent, it appears, that the great object of these adventurers, as it was of all others in that reign, was the search after mines of the precious metals. Raleigh was not himself in this expedition; the ships returned in the autumn with some commodities which told so well, that the company was encouraged to fit out a fleet of seven vessels for the following year, of which the command was given to Sir

Richard.
Richard Greenville, Raleigh’s relation. During this voyage they took possession of that tract of country which has been so famous, by the name bestowed upon it by queen Elizabeth, and not given, as it has been generally supposed, by Raleigh, of Virginia. After expending a large sum in repeated attempts to repair the misfortunes that had happened to the newly established colony, he assigned his patent to a company, referring to himself only a portion of the expected gold and silver ore. This enterprise probably made England first acquainted with tobacco, and also conferred upon it the much greater benefit of introducing the culture of the potato, first practiced on Raleigh’s estate in Ireland.

About this time he was chosen knight of the shire for the county of Devon, and very soon after the queen conferred upon him the honour of knighthood, an honour which the did not render cheaper by profiting it. In the year 1585 he fitted out another fleet for Virginia, in which he had good success, his ships, in their return, taking a prize worth 50,000l. He was likewise concerned in captain Davis’s undertaking for the discovery of the north-west passage; on which account a promontory in Davis’s Bay was called Mount Raleigh. For these public-spirited and expensive projects, the queen was pleased to make him some profitable grants; particularly two, the first giving him authority to license the retailers of wine throughout the kingdom, and the other of a feudatory in Ireland, consisting of twelve thousand acres, which he planted at his own expense, and many years after sold to Richard Boys, the first earl of Cork. In 1586 he was appointed senefchal of the duchies of Cornwall and Exeter, and lord-warden of the flanaries; and in 1588 he had seen rising in the queen’s favour, that the favourite minister, the earl of Leicester, took the alarm, and brought forward the earl of Effex as his competitor. But her majesty’s partiality was fully justified; it was, in this instance, extended to a man, who at all times pursued whatever appeared to him conducive to the public good, how little ever it turned to his private advantage. “With justice, therefore,” says Campbell, “was the wife queen Elizabeth liberal to such a man, who, whatever he received from her bounty with one hand, bestowed it immediately in acts glorious to the nation with the other.”

In the year preceding the attempt of the famous Spanish armada, sir Walter was captain in the queen’s guard, and her lieutenant-general for Cornwall. In the latter capacity he was active in disciplining the militia of the county; and he was one of the council of war to whom the consideration of the state means of opposing the dangers of that momentous period was committed. When the armada appeared in the Channel, he was one of the gallant volunteers who nobly joined the English fleet with ships of their own, and had a share in the defeat of the enemy. In 1589 he was among those who accompanied the expelled king of Portugal in his attempt to reanimate himself. The queen showed her continued approbation of his services, by making him gentleman of her privy-chamber, and augmenting the profits of his other places. This was no small favour in Raleigh’s estimation, for though in many respects of an elevated mind, fond of glory, splendid and liberal, he was likewise intent upon gain, and neglected no source of emolument which his court interest placed within his reach. He did not scruple, we are told by some of his biographers, though the fact is not noticed by Campbell and others, to take direct bribes for the exertion of his influence; and he is said to have received no less than ten thousand pounds for procuring a pardon for Mr. Littleton. See Biog. Brit. article Littleton.

On his return from his Portugal voyage he visited his Irish estates, and there either formed or renewed his acquaintance with the poet Spencer, who celebrates him under the title of the “Shepherd of the Ocean,” and acknowledges the obligation of having first made him known to the queen. To his Fairy Queen he likewise prefixed a letter to Raleigh, explanatory of its plan and design. The patronage of literature was one of the fled traits in the public characters of an age, in which men’s was singularly mixed with heroism. The naval enterprises of the reign of Elizabeth were for the most part predatory expeditions, set on foot by individuals for their private benefit, and encouraged, though but feebly aided, by the crown. In 1592 sir Walter Raleigh engaged in a considerable undertaking of this kind, with a view of attacking Panama, and intercepting the Spanish Plate fleet. He fitted out thirteen ships, by himself and his associates, which were joined by two of the queen’s men of war, and he was appointed general of the whole fleet. Scarcely had he set sail when he was recalled by his sovereign; proceeding, however, to Cape Finisterre, he divided his fleet into two squadrons, with cruizing orders, and then returned. One of the squadrons fell in with a rich prize, the capture of which was the only influence of success which attended the expedition. His ardour for war was shown by his support in parliament of a motion, that certain subsidies granted to the crown should be for the express purpose of carrying on a war offensive and defensive against Spain. To undermine his credit with the queen, Parzons, a Jesuit, published a libel against him, charging him with Atheism; the queen is said to have imbued some prejudice against him on this account, but he incurred her heavy displeasure by an intrigue with one of her maids of honour, the daughter of sir Nicholas Throgmorton. The consequences of this amour brought a scandal upon the court of the virgin queen; and though he made the best reparation in his power, by marrying the lady, his offence was punished by an imprisonment in the Tower for some months, and a subsequent banishment from the queen’s presence.

During his imprisonment he projected an expedition for the discovery of the empire of Guiana, which had already been visited by the Spaniards, and the extent and opulence of which had been the subject of many marvellous tales. Having obtained some preliminary information, from an old navigator whom he dispatched for the purpose, he embarked in person, in the month of February 1595, with a squadron of ships fitted out at a great expense, and failed to the island of Trinidad, where he made himself master of the town of St. Joseph; he then proceeded up the great river Oroonoko, but was obliged by the heat of the weather, and the difficulties of the navigation, to return, with doing nothing more than merely taking possession of the country in her majesty’s name. Unwilling to return without appearing to have done something, he published a work, entitled “Discovery of the large, rich, and beautiful Empire of Guiana;” which was evidently the result of a fertile imagination rather than of real observation, and which Hume Rigmatizes as a production “full of the groggest and most palpable lies that were attempted to be imposed on the credulity of mankind.”

Sir Walter had so far regained the good opinion of the queen, that he had a naval command in the expedition against Cadiz in 1596, under the earl of Effex and lord Ellingham. In the attack he was one of the leaders of the van, and by his valour and prudence contributed a full share to the successes of the glorious action. In the following year he failed as rear-admiral in the expedition of which Effex was commander-in-chief, and the purpose of which was to intercept the Spanish West India fleet. Arriving first with
his squadron at Faya], after waiting some time for Essex, he thought it expedient to make an attack on the place by himself, which proved successful. The commander-in-chief was mortified with this action, thinking it was designed to rob him of the glory due to him, and would have castrated Raleigh, if lord Thomas Howard had not interposed his services to effect an apparent reconciliation. On their return lord Essex published some remarks upon what had happened in the course of the voyage, in which he questioned every body's conduct but his own. "The queen, however," says Campbell, "taking time to inform herself, made a right judgment of the whole affair; in consequence of which she paid a due respect to every man's merit, and greater to none than to that of sir Walter Raleigh." During the remainder of this reign Raleigh chiefly appears as a member of parliament, and as an allottor of the privileges and interests of the people in the west, over whom his authority extended. That he was completely restored to the favour of his royal mistress is evident from the circumstance, that in 1661 he attended her in a progress through part of the kingdom. He was likewise appointed by her to receive the duke of Bourbon on his arrival as ambassador from France, and conferred with him on the subject of his mission. In the queen's last parliament sir Walter was a very active member, and distinguished himself upon all occasions, by opposing such bills as, under colour of deep policy, were contrived for the oppression of the middle and lower ranks of society. He witnessed the ruin of his great antagonist the earl of Essex, whose execution he indecently urged upon the minister Cecil; and he was even an eyewitness of the deed. Campbell, endeavouring to justify him in every thing, is evidently, in some instances, a panegyrist rather than a faithful historian. The decease of the queen, which soon followed the execution of her former favourite lord Essex, and which was probably hastened by it, gave a final, and to Raleigh a very unexpected, blow to his own prosperity.

When James came to the crown it was a fort of content between sir Walter Raleigh and sir Robert Cecil, who should obtain the confidence of his majesty; the latter, however, was admitted to the royal councils, to the exclusion of sir Walter Raleigh. In truth, James had a prepossassion against Raleigh, as having been the enemy of Essex, and still more, as having, with some others, entertained a design of forcing the king to agree to certain limitations with respect to the number of his countrymen whom he was to bring with him. Sir Walter's martial and enterprising spirit was also obnoxious to a prince of a pacific disposition. He was, therefore, received, barely with civility, a circumstance which preyed upon his high spirit, and was probably the means of throwing him into the party of the discontented. A conspiracy, for the purpose of placing upon the throne lady Arbella Stuart, was at this time formed, in which Raleigh in some measure participated. He was apprehended, and brought to trial on a charge of high treason; but, says the historian, his condemnation, upon the evidence produced, was one of the most disgraceful instances on record, of the base subversion of an English jury to the vindictive wishes of a court. His only accuser was lord Cobham, a man of bad character, and one who was deeply implicated in the plot, to whose proposals he had given ear, but probably without entering into, or even approving them. In his defence he displayed so much eloquence, temper, and force of argument, that none who had been highly prejudiced against him, were brought to regard him as an innocent victim, and, it should seem, from the testimony of contemporary historians, that all parties were ashamed of the injustice of his condemnation.

It is said that even Coke, the attorney-general, who treated Raleigh on his trial with all the abuse that belonged to his character, and was thought authorized by his office, exprelled surprise at the sentence, and declared that he had charged him with no more than misprision of treason. Three were executed for this plot, two were pardoned, and Raleigh was only reprieved and committed to the Tower. His wife, at her own earnest solicitation, was permitted to become his fellow-prisoner, and his youngest son was born in the Tower.

In Mr. Cayley's life of sir Walter Raleigh, published in London in 1858, we have a curious letter of lord Cecil, then secretary of state, to sir Thomas Parry, the English ambassador in France, in which he gives an account of the conspiracy just referred to, and of the motives which led the different persons to take a part in it. Sir Walter was indicted for conspiring to deprive the king of his government, to raise up faction within the realm, to alter the religion and bring in the Roman superstition, and to procure foreign enemies to invade the kingdom. The principal overt act laid in the indictment was, that sir Walter had a conference with lord Cobham, as to the best means of advancing Arabella Stuart to the crown and throne of this kingdom, and that they should apply to the king of Spain to procure his assistance in this cause. Sir Walter made an able stand in his trial against the legality of conviction upon the evidence of a single witness, but the judge, rendered infamious by his conduct on the trial, over-ruled the objections.

The active mind of sir Walter Raleigh was now left to exert itself within the walls of a prison, and its employment conduced more to his honour than his liberty perhaps would have done. Here he composed the greater part of his works, especially his "History of the World." Prince Henry, a youth of most amiable qualities, and as unlike his father as possible, contracted a generous admiration for the splendid talents of Raleigh, and cherished him in his solitary confinement by his friendship and correspondence. "No king," said the royal youth, "but my father would keep such a bird in a cage." Henry, however, died, and with him the hopes of deliverance vanished from the mind of the flate prisoner. At length, however, after twelve years' confinement, sir Walter obtained his liberation, but probably not without the use of bribes, applied to the new favourite Vilers. For the purpose of repairing his fortunes, he planned a new expedition to Guiana, and his report of a rich gold mine existing in that country was a sufficient inducement for a number of adventurers to engage in the scheme. He obtained a patent under the great seal from the king, for making a settlement in Guiana. James, however, in order to retain his hold upon him, did not grant him a pardon of the treasons of which he had been convicted. There is no doubt but sir Walter might have purchased a pardon, and, at one time, had thoughts of doing so. He even consulted sir Francis Bacon, whether it would not be advisable for him to give a round sum of money for a pardon in common form; to which the learned lawyer answered, "Sir, the knee timber of your voyage is money; spare your purse in this particular, for, upon my life, you have sufficient pardon for all that is past already, the king having under his broad seal made you admiral of your fleet, and given you power of the martial law over your officers and soldiers." Raleigh having employed all his resources in fitting out the expedition, failed for Guiana with twelve armed vessels in July 1617. He had not yet fail long before he was obliged to put into the harbour of Cork, by storms of weather, where he remained till the 15th of August. In November he arrived at Guiana,
Guiana, where he was received with the utmost joy by the Indians, who not only rendered him all the service in their power, but endeavoured to persuade him to end all his labours there, and take upon himself the sovereignty of the country, which, however, he readily refused. A violent and long continued sickness prevented him from undertaking the discovery of the mine in peron. This important affair he entrusted to one of his captains, Keymis: the scheme, however, proved abortive, the Spaniards having been before hand with him in the search of gold. Humę, for the purpose of expediting James, endeavours to shew that the real intention of Sir Walter Ralegh was to plunder the Spanish settlements, and neither to colonize, nor to work the mines. He assumes that Ralegh was a wilful deceiver in the expectations he had raised of vast subterraneous riches; but considering his character, it is surely more reasonable to believe that he was carried away by some vague ideas of this kind, and Hume admits that the Spaniards were at the very time working some mines. It will be readily admitted, that James did not imagine he was giving Ralegh a commission of hostilities against Spain, yet he must have known that the exclusive claims of that crown in South America rendered every interference with its dominion hostile in its eyes. The fact seems to be, that the expedition was undertaken with an intention to make the most of it, by any means within the power of the armament, and that the commander trusted to its success for justification before a court where bribery to favourites was omnipotent.

In this expedition Ralegh's eldest son lost his life, of which, and of the unfortunate issue of Keymis's undertaking, he reproached his captain very severely, who, without hesitation, put an end to his own life. Ralegh, with a heavy heart, returned homewards. In July 1618 he arrived at Plymouth, and in his journey to London he was arrested, and carried back to Plymouth. Twice he attempted to escape, but was secured and committed a prisoner to the Tower. James was exasperated at the injury which had been inflicted on Spain, a power then in amity with England, and which had been complimented of by the Spanish court in very strong terms. He was, moreover, about to enter into a more intimate connection with that court, and therefore, without hesitation, determined to sacrifice Ralegh to its resentment. Though his death had been determined on, it was difficult to take away his life. His conduct in the late expedition, though the want of successes had rendered it criminal in the eyes of the court, was far from being so in the sight of the nation; and though judges might have been found who would pronounce it treason, yet even in those days it was not easy to find a jury who would, without evidence, have found him guilty. The commissioners, therefore, who had been appointed to inquire into the matter, and who had frequently examined him, finally reported, that no ground of legal judgment could be drawn from what had passed in the expedition. Upon this, it was resolved to call him down to judgment upon his former sentence, which, says Campbell, was done, with all the circumstances of iniquity and brutality that can well be conceived. Being brought before the court of king's bench, his plea of an implied pardon, by his having acted under the king's commission since sentence had been pronounced, was over-ruled, and he was not permitted to enter into a vindication of his conduct in the late voyage. Execution was accordingly awarded, and the king's warrant for it produced, which had been signed and sealed before-hand.

"That this judgment was illegal," observes Dr. Campbell, "and that Sir Walter was really murdered, has often been said, and I believe, seldom doubted; but I think it has not been made so plain as it might be, and, therefore, in respect to his memory, I will attempt it, by shewing that the judgment was absolutely illegal, as well as manifestly iniquitous.

"It is a maxim in our law that the king can do no wrong; and most certain it is, that no king can do legal wrong, that is to say, can employ the law to unjust purposes. Sir Walter Ralegh, after his conviction, was dead in law, and, therefore, if king James's commission to him had not the virtue of a pardon, what was it? Did it empower a dead man to act, and not only to act, but to have a power over the lives and estates of the living? It either conveyed authority, or it did not. If it did convey authority, then Sir Walter was capable of receiving it; that is, he was no longer dead in law; or, in other words, he was pardoned. If it conveyed no authority, then this was an act of legal wrong. I cannot help the blunder; the absurdity is in the thing, and not in my expression. A commission under the privy seal, if not under the great seal, granted by the king, with the advice of his council, to a dead man; or, to put it otherwise, a lawful commission given to a man dead in law, is nonsensical not to be endured; and, therefore, to avoid this, we must conceive, as Sir Francis Bacon, and every other lawyer did, that the commission included, or rather conveyed, a pardon. Indeed, the same thing may be made out in many fewer words. Grace is not so strong a mark of royal favour as truth; and, therefore, where the latter appears, the law ought, and, indeed, does, preclude the former. This judgment, therefore, did not only murder Sir Walter Ralegh, but, in this instance, subverted the constitution, and ought to be looked upon, not only as an act of the baleful prostitution, but as the most flagrant violation of justice that ever was committed."

The sentence of death was pronounced on him one day, and put in execution on the following, Oct. 29, 1618, in Old Palace Yard. His behaviour on the scaffold was calm and manly. He addressed the people at some length; he said he never feared death, and much less at that time; that as to the manner of it, though to others it might seem grievous, yet for himself, he had rather die in this way than in a burning fever. He desired to see the axe, and feeling the edge of it, said to the sheriff, "This is a sharp medicine, but a sure remedy for all evils." Being asked which way he chose to place himself on the block, he replied, "To the heart be right, it is no matter which way the head lies," and giving the signal, he received the stroke with the most perfect composure. Such was the end of the illustrious Sir Walter Ralegh, in the 66th year of his age, by a sentence which was regarded as one of the most dishonourable measures of an odious administration. The panegyric upon his character by Dr. Campbell is much too highly coloured: Sir Walter Ralegh was not faultless, though in extent of capacity and vigour of mind he had few equals in an age that abounded with great men. His imprisonment was the occasion of his obtaining a high reputation as an author. His writings were on various topics, and are classed as poetical, geographical, political, philosophical, and historical. They are now but little known. His "History of the World," though not much read, is regarded with respect, as one of the best specimens of the English language of that time. The style is pure, nervous, and without pedantry. It is the style of a man of business as well as of a scholar. It has been many times reprinted, but the best edition is that of Oldys, in 1736. He brought down his history no farther than the overthrow of the Macedonian empire. Of his miscellaneous works, a collection in two volumes 8vo. was printed in 1748. Biog. Brit. Hume. Campbell. Cayley.

RALEIGH, or RAYLIEGH, in Geography, a market-town
and parish in the hundred of Rochford, and county of Essex, England, is situated at the distance of 14 miles S.E. by S. from Chelmsford, and 34 miles E. by N. from London. This place appears to have been anciently of considerable note. It was the head of the barony of Swene, and had a castle adjoining to it, of which some fragments and earth-works still remain. These consist of a mount, with an oval-shaped base, surrounded by a double ditch and rampart, and several outworks, particularly on the east side. The summit of the mount is divided; the western division being of a circular form, and 100 feet high; and the eastern one of an oval form, and lower: the principal ditch varies in width from 10 to 50 feet, and the interior vault is 50 feet high. The church here is an acent edifice, and contains an old tomb, greatly mutilated, but displaying the remains of very beautiful workmanship in the pointed style. The person whose memory it was intended to preserve is now unknown; the upper part, to which the inscription was probably affixed, being totally destroyed. The market at Raleigh is held on Saturday, weekly; and there is an annual fair on Trinity Monday. Hearne, in his edition of Leland's Itinerary (vol. iii. p. 8.), informs us that a custom-court was kept here, yearly, the Wednesday next after Michaelmas day, "The court," says that author, "is kept in the night, and without light, but as the eye gives, at a little hill without the town, called the King's hill, where the steward writes only with a candle, and not with an ink; and many men and masts of great worth hold of the same; and if it be one of strange court, where the steward calls them with as low a voice as possible he may; giving no notice when he goes to the hill to keep the same court; and he that attends not is deeply a meric, if the steward will." This is commonly called Lawtel-Court. Weaver, in his "Funeral Monuments," adds, respecting this custom, that he was informed, "that this vile attendance was imposed at the first upon certain tenants of divers manors hereabouts, for conspiring in this place, at such an unfeasable time, to raise a commotion." According to the parliamentary returns of 1811, Raleigh parish contains 162 houses, and 1,131 inhabitants. Beauties of England and Wales, vol. v. by E. W. Brayley and John Britton, F.S.A. 1810.

RALEIGH, a township of Essex county, in Upper Canada, W. of Harwich, bounded on the N. by the Thames, and S. by Lake Erie.

RALEIGH, a town of America, in Wake county, North Carolina, the present seat of government, about ten miles from Wake court-house. The general assembly of the state in December 1791, appropriated $20,000 towards erecting public buildings, and named it after the celebrated Sir Walter Raleigh, under whose direction the first settlement in North America was made at Roanoke in 1585, and in Albemarle found. The state-house is a large handsome building, and court good. The plan of the town is regular; the streets intersecting each other at right angles. It is, however, subject to the disadvantage of being remote from navigation: 61 miles N.E. of Fayetteville, 147 from Petersburg in Virginia, and 448 S.W. of Philadelphia.

RALEMO, a river of Chili, which runs into the Pacific ocean, S. lat. 37° 51'.

RALENDÖRF, a town of the duchy of Carinthia; 12 miles S. of Sazenburg.

RALESTEDE, a town of the duchy of Holstein; 8 miles E. of Hamburg.

RALICOTTA, a town of Hindoo lan, in Viliapour; 31 miles N. of Anamfagar.

RALLENTANDO, Ital., a musical term of late invention, for relaxing the measure at particular parts of a composition, which, when done by a great master, manifests feeling and intelligence; but when attempted by mean performers, it has no other effect on an audience than that of breaking time; and we think that this refinement is often abused. It has been chiefly practised in France, and in favour of affectation, and that overcharged tenderness which renders the national airs tendres so disagreeable, or so ridiculous, to the natives of all other countries.

RALLUS, the Rail, in Ornithology, a genus of birds of the order Gallé: the generic character is, that the bill is thickish at the base, attenuated on the back towards the tip, compressed, a little incurved, pointed; the tongue is rough at the tip; the body is short; the feet have four chief toes. There are seventeen species.

*CRAC; land rail, crake, corn crake, daker hen, &c. Of this species the wings are of a rufily-red; the bill and legs of a brownish-ash; the irides are of a hazel colour; the feathers of the body are of a reddish-brown; the upper ones are black in the middle; the chin is very pale; and the belly is of a whitish-yellow. It is about nine or ten inches long, and inhabits the shady parts of Europe and Asia. From the circumference of its appearing at the same time with the quail, and frequenting the same places, it has been denominated the king of the quails. Its well-known cry is first heard as soon as the grasses become long enough to shelter it, and continues till the grass is cut. The bird, however, is seldom seen, as it walks in the thickest parts of the herbage, and runs to nimble through it, winding and doubling in every direction, that is difficult to come near it. When it is hard pressed by the dogs, it sometimes hops short and skits down, by which means its too eager pursuer overflows the spot and loses the trace. It seldom springs but when driven to extremities, and generally flies with its legs hanging down, but never to a great distance. As soon as it alights, it runs off, and before the fowler has reached the spot, the bird is, at a considerable distance. It emigrates, appearing with us about the latter end of April, and departing in October. On its first appearance, and till the female begins to sit, the male is frequently heard to make a singular kind of noise, much resembling that of a comb when the finger is drawn along the teeth of it, and which has been used as a decoy. When they first arrive, they are very lean, but before their departure, they become excessively fat, and are much sought after for the delicacy of their flesh. They lay from twelve to fifteen eggs in the grass, of a dirty whitish colour, with a few yellow spots; the flesh is excellent. There are two varieties, thus described: 1. Rufous brown, beneath paler; wings and tail deeper; the chin and vent are white; the legs are dusky red. This is found in the island of Jamaica. It is larger and black. 2. Reddish-grey beneath, and wing-coverts rufily-brown. This species inhabits China; the legs are of a dusky colour.

AQUATICS; Water Rail. Wings grey spotted with black; flanks spotted with white; bill orange beneath, but black and reddish at the base; the irides are red; the feathers of the upper part of the body are of an olive-brown, and black in the middle; the lower ones are cinereous; those of the lower part of the belly are edged with rufous; quill-feathers dusky; the lower tail-coverts are white; the tail-feathers are short and black; the two middle ones at the tip, and the others, are edged with farrinuous; the legs are of a dusky red. It is about twelve inches long, but does not weigh more than four ounces. It is found in the watery places in Europe and Asia. It is sometimes, but not in
any great numbers, met with in various parts of Great Britain, in low situations, about water courses and rivulets, where it feeds shelter among fedges, rushes, and reeds, and is seldom put to flight, depending on its legs for safety. When roused it flies only to small distances, and in a heavy and very awkward manner, with its legs hanging down. It runs nimbly, and frequently flies up its tail. The neck is made of fedge and coarse grals, among the thickest aquatic plants, or in willow beds. The female lays six or more eggs, rather larger than those of a blackbird, of a pure white colour. This bird continues with us all the year, and by many it is erroneously believed to be the land rail metamorphosed in the autumn; but the different bills which the two birds have constitute an essential distinction.

Porzana, Spotted gallinule, or spotted water hen.

This species has the two middle tail-feathers edged with white; the bill and legs are of a pale olive. It inhabits Europe and North America, and is generally found on the sides of small streams, hiding itself among the bushes; it is nine inches long. This bird is described as having a greenish-yellow bill; its irides are hazel, and head brown, spotted with black. The line over the eye is of a pale grey; the neck above and flanks are of a brown-ash, with small white spots; the back and wing-coverts are olive, with black stripes, and near the edges of the feathers with white spots, the greater with white stripes and lines; the cheeks, chin, and throat, are of a pale grey, with brown spots; the breast is brown, with white spots; the belly is variegated with cinereous and white; the vent is of an ochre-yellow. This bird is extremely timid and squirell-like, and is but seldom seen in Great Britain, eluding observation by its perpetual vigilance and lurking habits. Its neck is formed with singular care, of matted rushes, and materials which will float on the water, on which it remains tied, by some filaments, to the slacks of reeds, by which it is prevented from being carried away by the tide or current. The bird is in great esteem for the table.

Crepitans, Clapper Rallus. Bill and legs brown; body above olive, the feathers ash at the edges; chin white, throat and breast yellowish-brown. This species inhabits New York, and is from fourteen to sixteen inches long.

Fuscus, Brown Rallus. This brown, as its specific name imports; its vent is waved with white; the legs are yellow. It inhabits the Philippine isles, and is seven inches long. The belly beneath is light chestnut, on the belly it is inclining to grey; the tail is barred with white and black.

Striatus, Streaked Rallus. Blackish, waved with white; chin reddish. The bill of this species is of a horn colour; the crown is varied with dusky bay; the nape is bay; neck, back, shoulders, and rump, brown, with whitish spots; the wing-coverts are marked with a few transverse whitish streaks; the chin is of a reddish-white; the cheeks, throat, breast, and upper part of the belly, cinereous, with a tinge of olive; the lower part is barred with dusky and white; quill-feathers brown, the outer bands reddish-white, the inner white; the tail is brown with white lines; the legs are of a greyish-brown. It inhabits the Philippine isles, is eight inches long, and is probably a variety of the philippensis.

Torquatus, Banded Rallus. Brown, beneath waved with white; it has a white line below the eyes. This allo is found in the Philippine isles, and is twelve inches long. The bill and legs are grey-brown; cheeks and chin black. The body beneath is transversely streaked with black and white; the collar is of a bay colour; the quill-feathers on the outer edge paler; bands within on the first three white, the six next reddish-bay.

Philippensis, Philippine Rallus. The specific character of this bird is brown, but beneath it is barred with grey; the eye-brows are white, and the neck beneath has a reddish cast. There are three other varieties, thus described:

1. Red-brown, spotted and streaked with black and white; head chestnut; body beneath and eye-brows cinereous; this, notwithstanding its name, is found at Otaheite.
2. Brown, spotted and streaked with white, beneath white; eye-brows grey; the tail is barred with brown and white; this inhabits Tongataboo.
3. Above brown, beneath ash; back and wings lined with white spots; the belly beneath is white, with blackish bars. This is about eleven inches long, and is found in the Philippine islands.

Ecaudatus, Tailless Rallus. Olive; beneath blueish; body transversely waved with black; eye-brows white. It inhabits Otaheite. The bill is blackish, and the upper part of the head is of a pale brown; the orbits are black; over the eyes, on each side the head, it has a broad white line; the body above is of a deep glossy olive, with a tinge of olive on the shoulders; the vent is of a pale yellow; the tail is so short as to be scarcely perceptible; the covert are of a pale blue.

Carolinus; Soree. This bird is brown; the frontlet is black; the breast is of a lead colour; the bill is yellow; the legs are greenish. It inhabits Virginia, and is from seven to eight inches long; this is a capital bird for the table. The irides of this bird are red; the crown and body above are brown, marked with black spots; the face and chin are black; but the rest of the neck, temples, and breast, are of a blueish-ash; the belly and outer edge of the wings are white; the wings and tail are brown.

Pheniculus; Red-tailed Rallus. This species is black but beneath it is white; the bill and legs are greenish; the front is naked and of a fleshy colour; the vent and tail of a rufiy red. It is found in the island of Ceylon, and is about nine inches long. The bill and legs are tinged with red; the crown and cheeks are pure white; the quill-feathers are spotted with blue. There are two varieties. Above cinereous, beneath white; the belly and vent are red. This is an inhabitant of China, and is fifteen inches long. 2. The front of this is white; the vent is red, and the legs are yellow. It is found in Madagascar, and is longer than the last.

Virginianus; Virginian Rallus. Brown, without spots; the bill and legs are brown. It inhabits Virginia, and is probably a variety of the R. aquaticus.

Ferrugineus; Red-breasted Rallus. This bird is dusky above, and cinereous beneath; the neck and breast are ferruginous; the bill is pale, and the legs yellow. It is nine inches long; the eye-brows are pale, and the flanks are marked transverse, narrow, white lines.

Capensis; Cape Rallus. This species is of a ferruginous colour; but the lower part of the breast, belly, vent, wings, and tail, are waved with black and white; the bill is black, and the legs are of a blood-red. It inhabits the Cape of Good Hope and Ceylon; and is of the fize of the R. crex. The two middle tail-feathers are ferruginous.

Ceruleus; Blue-necked Rallus. This is of a bay colour above, but blueish beneath; the bill and legs are red; the vent is white, and the belly is marked with transverse black streaks. It inhabits the Cape of Good Hope; it is seven and a half inches long.

Zeylanicus; Ceylon Rallus. The head of this bird is dusky; the body above is ferruginous, beneath it is reddish, waved with brown; the first quill-feathers are black; the
bill and legs are red. It is found, as its name imports, at Ceylon; it is larger than the R. aquaticus, and has a long tail.

**Australis;** Tragostylyte Rallus. Rufy bill; wings and tail deep brown; the feathers are barred with black. It inhabits New Zealand, and is seventeen inches long. The bill and legs are yellow; the body above is of a rufy brown, beneath rufy red; and the tail-feathers are waved with black.

**Pacificus;** Pacific Rallus. Black, speckled with white; wings barred; body beneath whitish; the head is brown, the breast is of a blue-bill. It is found in Otaheite, and the neighbouring isles. Bill red, the legs are of a flesh colour; the chin and eye-brows are white; the nape of the neck is rufy.

**Tabuenis;** Tabuan Rallus. Brownish-black; beneath it is of a dusky colour; the bill is black, and the legs are bay. A variety has its vent streaked with black and white; the legs are red. It inhabits the South-sea islands, and is six inches and a half long. The eye-lids and irides are red.

**Niger;** Black Rallus. Black; bill red at the base, brown at the tip; the legs are brown or red. This is an African bird, and is nine inches long.

**Sandickenis;** Sandwich Rallus. This is of a pale ferruginous colour; but the bill is of a dusky bill; the legs are of a dull flesh colour. A variety has a yellowish bill and legs. It inhabits the Sandwich isles; and another variety is very small, and found in the Tanna isles.

**Taitiensis;** Otaheite Rallus. Cinerous; body above red-brown; the bill, rounded tail, and claws, are black. This inhabits Otaheite and the Friendly isles, and is about six inches long. The quill-feathers are dusky and edged with white; the legs are yellow.

**Obscurs;** Dusty Rallus. This is brown streaked with black, beneath it is of a rufy brown; the bill is black, and the legs are of a red-brown. It inhabits the Sandwich isles, and is six inches long; the edge of the mandibles is yellowish.

**Longirostris;** Long-billed Rallus. The upper part of this species is cinereous, spotted with brown, beneath it is rufous white; the flanks are transversely waved with white, the bill is large and of a ferruginous colour. It inhabits Cayenne, and is from nine to twelve inches long. The bill is tipt with brown; the legs are yellow, and the chin whitish.

**Variegatus;** Variegated Rallus. This bird is streaked and spotted with white and black; the hind-head is dusky; the bill is yellowish; the chin is white; and the legs are yellow. It inhabits Cayenne, and is eleven inches long. The wings are brown, the coverts are spotted with white; some of the middle tail-feathers are edged with white.

**Cayennensis;** Cayenne Rallus. The crown of this bird is rufous; the body above is of an olive-brown; beneath it is rufous; the ocular band is blackish; the quill-feathers are black; the bill is brown, and the legs gray. There is a variety having its crown gray; chin and vent reddish-white. It inhabits Cayenne and Guiana; it is eight inches long; in the evening it is noisy and gregarious, by day it is solitary; it builds in the forked branch of a tree, near the ground. The vent is pale.

**Jamaicensis;** Jamaica Rallus. Above reddish-brown with black streaks; the bill and chin are black; the throat and breast are of a blue-bill; the belly is marked with white and brown lines. It, as its name imports, inhabits Jamaica, and is six inches long. The bill is reddish at the base; wing-coverts brown, spotted with white; the quill-feathers are of a reddish-brown, with black lines, the coverts and tail-feathers are spotted with white, and the legs brown.

**Mixtus;** the Little Rallus. This is brown, but beneath it is yellowish; eye-brows, streaks on the back, and spots on the wing-coverts, white; tail barred black and white. A variety has the middle of the neck above rufous; the belly and vent are waved with white and black. It inhabits Cayenne and Jamaica, and is five inches long. The bill is brown; the wing-coverts are black; the chin is whitish, and the legs are yellow.

**Pusillus;** Dwarf Rallus. Stripped with ferruginous and black; the body beneath is blackish, with narrow white bands; the throat and breast are blueish. This is found near the lakes of Dauria, and is of the size of a lark. The face, neck beneath, and middle of the breast longitudinally, are blueish; the middle of the chin is whitish; the longitudinal band through the eyes of a pale rufous; the back is scattered with white longitudinal lines; the legs are greenish.

**Barbary;** Barbary Rallus. This is of a ferruginous colour; the bill is black; the wings are spotted with white; the rump is streaked above with white and black, and beneath with white; the legs are of a dusky brown. This, as its name imports, is an inhabitant of Barbary, and is the size of a sparrow.

**Duleus;** Doubtful Rallus. Stripped with brown and ferruginous; the belly is white; the flanks are barred with brown and rufous black; the first quill-feathers without are longitudinally white. It is the size of the common gallinule. The face is of a pale rufous colour; the chin is of a dirty white, surrounding a broad brown collar; the fides are brown; the bill and legs greenish-black.

**Rallying;** in War, the reeling, or calling together of troops, a breach, routed, and put to flight.

**Ralph, James, in Biography, a miscellaneous writer, defended probably from mean parentage,** was the intimate friend of Dr. Franklin, who speaks of him as ingenious and shrewd, gentle in his address, and extremely eloquent. Franklin knew him in America, and though he does not mention what Ralph's situation then was, yet as he wrote a fine hand, and was well versed in accounts, it is imagined he was a schoolmaster. In 1725 Ralph accompanied Franklin to England, with a resolution of not returning to America, where he left his wife, with whom, and with whose family, he had lived on ill terms. In London he was, for a considerable time, supported by his friend Franklin, till their intimacy was dissolved, when Ralph considered the quarrel as a complete discharge of the debt which he owed his benefactor. Ralph changed his name to that of Franklin, which he thought necessary, having formed a new female connection, and settled as a schoolmaster in a village in Berkshire. From this time there is no regular narrative of his life, which was probably passed as a hired party writer. He is spoken of with much contempt in the *Dunciad,* as the author of a poem called Night:—

"Silence, ye wolves! while Ralph to Cynthia howls,
And makes night hideous—Answyr him, ye owls."

In a note, it is said he wrote a swearing piece, entitled "Sawney," very abusive of Swift, Gay, and Pope; that he panegyrized his own works in the journals, was wholly illiterate, wrote plays, and was employed in a political newspaper. The fate of Pope must be taken with much limitation, it being inspired by party motives: Ralph having recommended himself to persons in power at the beginning of George II.'s reign, would for that reason be obnoxious to Pope and his friends. He became an able writer
writer in prose, and was author of many political pamphlets, which were much applauded in their time; but his chief work was "The History of England during the Reigns of William, Anne, and George I.," with an introductory Review of the Reign of the Brothers Charles II. and James II., in which are to be found the Seeds of the Revolution. By a Lover of Truth and Liberty," 2 vols. fol. 1774-6.

This work obtained the plaudits of Mr. Fox, who, in his posthumous historical fragment, speaks of the author as an historian of great acuteness as well as diligence. The last publication of this author was entitled "The Cafe of Authors by Proprietors or Trade, slated with regard to Booksellers, the Stage, and the Public," which is laid to contain much good sense and lively satire. Mr. Ralph did at Chiswick, in the year 1762. Gen. Biog.

RAM, in Geography, a town of European Turkey, in Servia, on the S. side of the Danube; 10 miles E. of Paffarowitz.

RAM, in Agriculture, the male of the sheep kind. It may be observed, that the rams of different breeds of sheep vary greatly in their forms, wool, and fleece, and other properties; but the following description by that excellent flock-farmer, Mr. Culley, deferves the attention of the breeder and grazer. According to him, his head should be fine and small, his nostrils wide and expanded, his eyes prominent, and rather bold or daring, ears thin, his collar full from his breast and shoulders, but tapering gradually all the way to where the neck and head join, which should be very fine and graceful, being perfectly free from any coarse leather hanging down; the shoulders broad and full, which must at the same time join so easy to the collar forward, and chine backward, as to leave not the least hollow in every place; the mutton upon his arm or fore-thigh must come quite to the knee; his legs upright, with a clean fine bone, being equally clear from superfluous linn and coarse hairy wool from the knee and hough downwards: the breast broad and well forward, which will keep his fore-legs at a proper wideness; his girth or chest full and deep, and instead of a hollow behind the shoulders, that part by some called the fore-flank should be quite full; the back and loins broad, flat, and straight from which the main rife with a fine circular arch; his belly straight; the quarters long and full, with the mutton quite down to the hough, which should neither fland in nor out; his twist, or junction of the inside of the thighs, deep, wide, and full, which, with the broad brest, will keep his fore-legs open and upright; the whole body covered with a thin pelt, and that with fine, bright, soft wool. It is observed, that the nearer any breed of sheep comes up to the above description, the nearer they approach towards excellence of form.

But though this is a very correct, appropriate, and admirable description of a finely-formed ram, objections have been made by some to a few of the properties which are laid down. Width and expansion of the nostrils in sheep, it is supposed, are liable to cause the lower parts of the noes to be too thick and large; while in naturally good and improved forms, the lower parts of the noes and mouths are for the most part small. Nor is the prominent and bold daring eye held in more estimation, as it is thought not to shew a good disposition; but, on the contrary, to display too much quickness and activity, or wildness of nature in the animal. Opinions, however, differ much on this point among sheep-farmers; and a lively quick eye is almost always considered as favourable to a good disposition.

Rams naturally possess more boldness and courage than either wethers or ewes; and they are very apt, unless great care is taken, to acquire mischievous habits of attacking persons or animals that may by accident approach them.

In some sheep-districts the breeders are greatly in favour of large rams, but in others those of a smaller size are preferred; the choice of the size of the rams should, however, in every instance, be regulated by the nature and abundance of the keep, or the quality of the lands, as it is utterly impossible that the inferior forts of pastures can keep sheep-flock of the large size, as in those of the better kinds; and it would be highly disadvantageous in the best rich forts to have a small-sized flock when they could support a large one in an equally perfect manner. Middle-sized rams are, upon the whole, the most suitable and proper for lands in general, and for all the purposes of the breeder.

The growth and constitutions of young rams should never be suffered to be endangered by their having too great a number of ewes, as is too frequently the practice with sheep-breeders.

It is a very improper custom, but one which prevails with the graziers in some sheep-districts, to keep all their rams, perhaps to the amount of from twenty to fifty or more of all kinds, in one field or pasture; as their contents are often so violent, especially about the riding time, as to caufe the los of one or two rams or each in all such cafes. This practice is the most common in the sheep-districts towards the southern part of the island, being seldom met with in those of the midland or more northern parts. It ought to be every where done away with.

The old rams are now almost always got quit of by being fattened as rams, and fold at the neighbouring markets, or to butchers, at a very inferior price, there being often much competition for this sort of low-priced meat in some situations. It was formerly, however, the custom in some places to kill them before they were fattened and fold to the butchers or other ways, but much injury and loss being found to be infinale by that method, it has been left off; it being now concluded, on the whole, that the loss by knitting the rams is greater than that which is suffered in the reduction of the price of ram mutton.

The practice of letting out rams in the midland districts for the purpose of improving the breeds of sheep, having produced such beneficial effects, the rife, nature, and progres of it may deserve the attention of the flock-farmer. It has been ably and accurately delineated, in the following manner, by Mr. Marhail, in his Rural Economy of that part of the kingdom.

It is flated, that in this district, in general, the management respecting rams is similar to that of other parts of the island; the breeders rearing or purchasing them. But that it is observable, however, that the advocates of the old breeds, though they will not adopt the modern flock, have fallen, in some degree, into the modern practice of letting by the feafon. But that the rams of the modern breed are never fold; but are palled from breeder to breeder, by the feafon only. And that for the purpose of promoting this intercoure, each principal breeder has his flowe of rams; commencing, by common consent, the 8th of June, and lasting until Michaelmas, or until the feafon of letting be past. That during a few weeks after the shows commence, every ram-breeder may be said to keep open house. Breeders and others, from all quarters of the kingdom, as well as the promoters of the breed who reside in the neighbourhood, attend these shows; going, in parties, from one to another: some to take, others to see and pass their judgment. And that at these private exhibitions close with a public show, at Leicester, the roth of October; when rams of every description, but molly an inferior sort of the improved
proved breed, are collected; being brought in waggon; many of them from a considerable distance; some to be field, but chiefly to be let for the season. That this show has been held, he believes, time immemorial; not, however, for the purpose of letting, but for that of sale. But the letting of rams by the season has long, he understands, been a practice in Lincolnshire. However, the origin, in the midland districts, may be traced—to a ram let by Mr. Bakewell, at Leicester fair, about forty years ago, at the low price of fifteen shillings. But humble, however, as was this beginning, it proved, Mr. Marshall says, to be the first stone of the foundation of a department of rural business, that has already risen to an astonishing height, and may, for some length of time, continue to bring in a copious source of wealth to the country. In the management of this business, the principal ram-breeders have annually, twenty, thirty, or perhaps forty ram-lambs; cattexplain being seldom applied, in the first instance, to the produce of a valuable ram. For, in the choice of these lambs, they are led more by blood, or parentage, than by form; on which, at an early age, little dependance can be placed. He adds, that their treatment, from the time they are weaned, in July or August, until the time of shearing, the first week in June, confines in giving them every indulgence of keep; in order to push them forward for the show: it being the common practice to let such as are fit to be let the first season; while they are yet yearlings—progressively sheep. Their first paffure, after weaning, is pretty generally, he believes, clover that has been mown early, and has got a second time into head; the heads of clover being considered as a most forcing food for sheep. After this goes off, turnips, cabbages, colewort, with hay, and report fays, with corn. But the use of this the breeders severally deny, though, collectively, they may be liable to the charge. However this may be, something considerable depends on the art of making up—not lambs only, but rams of all ages. Fat, like charity, covers a multitude of faults; and, besides, is the bell evidence their owners can produce, of their fattening quality,—their natural propensity to a rate of fatness; while in the fatness of the sheep is seen their degree of inclination to fat at an early age. And that the fattening quality being the one thing needed in grazing stock, and being found, in some considerable degree, as well, to be hereditary,—the fatness rams are of course the left; though other attachments, well or ill placed, as to form, or fashionable points, will perhaps have equal or greater weight in the minds of some men, even in this enlightened age and district. And the shearrings, which will not make up sufficiently, as to form and fatness, are either kept on to another year, to give them a fair chance, or are castrated, or butchered, while sheep.

With regard to the showing, it is remarked, that the shows of the principal breeders confit, by common consent, of forty rams each, mostly from one to five years old, they being seldom found efficient after that age; some, however, will continue in vigour to the fifth or seventh year. And that, during the show, they are mostly kept in small inclosures, of two, three, or four acres; with three, four, or more rams in each, according to their ages, and the advancement of the season. And in a corner, or other convenient part of each paddock, a small pen, made with hurdles, is placed; for the purpose of handling them. Into these pens they go, through hurdles, as tractably as worked oxen to their stalls. Indeed, the old rams, from the unwieldiness of their frame, and the load of fat they have to carry at this season, as well as from habit, will suffer themselves to be handled abroad; and even appear to take pleasure in the respect which they have shown them. But it is observed, that of late a new method of showing has been struck out by the leading breeder, and adopted by one at least of his followers. Instead of showing them abroad, and driving three or four of them up together in a pen, they are shut up in hovels, and brought out separately, being never seen together. He thinks, that among accurate judges, this mode of showing may be well enough; but to those who have had less experience it gives offence, as it deprives them of their best guide, comparison; and he can see no fair advantage accruing from it to the latter.

It is remarked, that though the desirable points of a ram are such as have been noticed, the choice of the hirer is determined, in some measure, by the intention for which he is about to hire: as whether it be that of getting wedders, or mere grazing flock; or rams for the purpose of letting. Hence the grazier and the ram-breeder choose different sheep, so as to suit their different purposes. He adds, that the characteristic difference between what is termed a ram-getter and a wedder-getter, or a good grazer's sheep, is that of the former being every where cleaner and finer, the head small, the bone and offal light, the flesh good, and the form beautiful. The mere grazer likes a ram no worse for having a strength of frame, and is less ferulous about his form than the ram-breeder, whose great object is fineness: his ewes, and the natural tendency of the breed, serve to give his offspring size and sufficiency when it is wanted.

In respect to the practice of letting, it is observed, that a novel circumstance has likewise taken place lately in the business of letting. The long established custom of letting a price was exploded, at least by the late Mr. Bakewell, and one of his disciples; whose cousin were left to make their own valuations, and bid what they pleased. But this, as well as showing them separately, is observed, gives great offence, especially to strangers, who cannot brook the idea of being both buyers and sellers. The latter, however, has more than one advantage in referring the price, provided he do not thereby drive away his customers: he is, in effect, letting to the best bidder. Besides, he is, through this means, enabled to regulate his prices to his customers, without giving any of them pointed offence: for as the principal breeders are, in this respect, if their own customers, it is no more than common good policy, in the leader at least, to advance himself, and keep back those who prefers upon him closer. It is, therefore, good management, Mr. Marshall thinks, in him to let a superior ram to an inferior breeder, whose ewes are yet of bafe blood, at a lower price than to one who is farther advanced, and whose ewes perhaps are nearly equal to his own: for if the hirer may not thereby be able to get the lead from him, he may run away with part of the best prices; and the only line the leader has to tread is, either to refuse him, or to make him pay in the first instance. And again; sometimes two or three capital breeders will join in the hiring of one superior ram; and, in this case, the breed being more widely dispersed, the price ought to be, and always is advanced, in proportion to the number of partners there may be in the busines. Hence, in the leader, a reveration of price may he allowable, especially in the letting of first-rate rams.

He observes, in regard to the conditions of letting, that notwithstanding the number of years the letting of rams has now been in use, and the extraordinary height to which the prices have risen, the transaction does not appear to have yet received any settled form; nor to have been rendered legally binding, by any written articles, or conditions of letting; much being still left to the humour of the parties. It is, however, generally understood, that the price agreed upon...
RAM.

upon shall not be paid, unless the ram in contract, or another as good, impregnate the tupulated number of ewes. If, through accident or inability, part only be impregnated, a proportional part of the price is abated. If he die while at ride, the losse falls on the latter, whether his death happens through accident or neglect; no cafe, he understands, having yet been otherwise determined. It is likewise under-

flood, that the hire shall not suffer him to serve any other than his own ewes; and of these, no more than a tupulated number, which is proportioned to the age or ability of the ram, and the mode of using him. And further, that if a grazier hire a valuable ram, at a wedder-getter’s price, (which is not unusual at the wane of a seafon, when valuable rams happen to be unlet,) it is underflood, or rather agreed, that he shall not rear rams from him; a condition which may frequently be advantageous to both parties. The letter pockets five or ten guineas, which otherwise he might not have had; and the hiree, by suffering himself to be “tied down,” as it is termed, gets a greater improvement in his flock than otherwise he could have got for the same money. He adds, that the time of paying the money is, he understands, undefined; seldom, he believes, until after the ewes have brought proofs of the ram’s efficiency, or after the lambing seafon.

It is obferved, that with regard to the prices for letting rams by the seafon, that from the firit letting to the year 1780, the prices kept gradually rising from fifteen fhillings to a guinea; and from one guinea to ten. In 1780, Mr. Bakewell leferval at ten guineas each; and what is rather inexpllicable, Mr. Parkifon of Quarrendon leferv one, the fame year, for twenty-five guineas, a price which then altonifed the whole country. That from that time to 1786, Mr. Bakewell’s flock rose rapidly, from ten to a hundred guineas; and that year he let two-thirds of one ram (referving one-third of the usual number of ewes to himself) to two principal breeders, for an hundred guineas each; the entire fervices of the ram being rated at three hundred guineas. This excellent breeder making that year, by letting twenty rams only, more than a thousand pounds! and that, since that time, the prices have been still rising. Four hundred guineas have been repeatedly given. The above breeder, this year (1789), makes, he understands, twelve hundred guineas by three rams, (brothers he believes,) two thonfand of feven, and of his whole letting full three hundred guineas! And that he now lets nothing under twenty guineas; a welljudged regulation, which Mr. Marshall thinks will probably be beneficial both to himself and his customers.

It is added, that, befide this extraordinary sum made by Mr. Bakewell, there are fix or seven other breeders who make from five hundred to a thoufand guineas each. The whole amount of monies produced this year, in the midland counties, by letting rams of the modern breed for one seafon only, is estimated, by thofe who are adequate to the subject, Mr. Marshall fays, at the almost incredible sum of ten thoufand pounds. He known that it is a popular idea, efpecially of thofe who, living at a diftance, have only heard of thofe extraordinary things, without having an opportunity of coming at facts, that the extravagant prices which are talked of are merely nominal; the principal part of the money being returned, the actual prices given being small, in proportion to thofe held out. This, however, is, he believes, and on the best authority, an erroneous idea. At the firit setting out of the high prices, there might be some tranfactions of that nature; but if ever they exited, they have ceafed long ago. Mr. Bakewell at preffent has the name, at leaft, of being parfimonious, even to the fheepfords

of the flocks on which his rams are employed. His highest preffent, he understands, is five fhillings; if the price be under five guineas, only half a crown. But the enormous-ness of these prices may be explained, he thinks, on other grounds. The high prices are not given, he fays, by graziers, for the purpose of getting wedders, or grazing flock; but by ram-breeders, for the purpose of getting rams, to be let to graziers: the highest being given by the principal breeders only, not for the purpose of getting rams to let to graziers as wedder-getters, but for that of getting rams, to be let out again to inferior fup-men, as ram-geters.

It is further flated, that the graziers’ prices run, even now, from one to ten guineas. He has not heard of more than ten guineas being given, by a mere grazier, for a ram, for the fole purpose of getting grazing flock: five or fix guineas is the common price. And fuppofing he gives the highest price, ten guineas, and that the ram serves a hundred ewes, (fome single, fome double,) the expefence of getting amounts to no more than two fhillings a head; which is inconfiderable, compared with the difference between a well and an ill grazing fheef, between a fheep that will get as fat at two years old as another will at three; or, in other words, which will, at two years and a half old, fetch ten or fifteen fhillings more than his comrades of another breed, but of the fame natural fize, and going in the same pallure, or feeding on the fame fort of food. In refpeft to the middle prices, as thofe from twenty to fifty guineas, they are, under the preffent circumstances, equally reconcilable, he thinks, to common fefne. If a breeder, who gives fifty guineas, rear ten tolerable rams fit for the grazier’s fervice, and let them at five guineas each, he brings himself home, even the firft feadon of letting, befide having the rams for another and another feadon, and befide a general improvement in his flock for the future. And thofe who give the higher prices, as one to two hundred guineas, have, or ought to have, proper bales to build upon, fufficient flocks of wellbred ewes; in which cafe, they have a fair chance of producing ram-getters, worth, while the preffent fpirit of improvement falls, twenty to fifty guineas a feadon. And that with refpeét to the very high prices, they are given by a few firft-rate breeders, who are playing a high game, running a hard race, for the pride and profit of being a leader, when Mr. Bakewell is not; a contention which may laft as long as Mr. Bakewell, and be at once an honour to his genius, and a reward of his fervices.

In refpeét to the treatment of rams after letting, it is remarked that the breeders of rams, as well as of bulls, find it expedient to reduce them from the eumonymous rate in which they are fhewn, previous to the feafon of employment; the old rams, in particular, being frequently returned upon their hand, non-efficient. Hence, as they are let, they are transferred to private pallures, and moderate keep; it being a pretty general rule not to throw a ram after he is let, or contracted for to a perfon.

In the fending out let rams, the ufual time of beginning is the middle of September: the means of conveyance, carriages of two wheels with fprings, or hung in flings; fome of them being large enough to hold four rams. In thefe they travel from twenty to thirty miles a day; being sometimes fenf, in this way, two or three hundred miles, and sometimes more.

It has been obferved by the fame writer, that the manner of ufing these rams has lately received a very great improvement. Instead of turning them loose among the ewes at large, as heretofore, and agreeably to the univerfal practice of the ifland, they are kept apart, in a separate paddock or small
in small inclosure, with a couple of ewes only each, to make them roll quietly; having the ewes of the flock brought to them singly, and leaping each only once. He thinks, by this judicious and accurate regulation, a ram is enabled to impregnate near twice the number of ewes he would do, if turned loose among them, especially a young ram. And he adds, that, in the old practice, fifty or eighty ewes were esteemed the full number for a ram; in the new, from a hundred to a hundred and twenty are allowed. Seven score have been served by one ram in a season: this is, however, much too great a number.

And while at ride, the treatment of the ram is merely that of keeping him well, and free from disorders; suffuring him to serve no other than the hirer’s own ewes, and of these the limited number only, and to return him safe when he has done; generally the beginning of December: or, if the hirer has met him on the road, (which is customary,) the latter, in return, meets him on his journey home. And the after treatment consists in starving, by every deviſeable means, to reload his carcasse, and make him fat and handsome for the ensuing saw, in order that he may be let again with advantage.

This is the whole of the plan that was purpored in that distirct, which has led the way to so much improvement in the breeding of sheep flock; and from which the country has derived such vast benefits, and such a number of advantages. But though the above practices have not been lately carried on to their former extent, they are still very considerable. See SHEEP.

It is remarked, that the practice of hiring rams in Romney Marsh is not carried on with the same degree of spirit as it is in Leicestershire, and that rams were of more value for the hiring season some time ago than they are at present, especially when the marts of the above county took place, as then from twenty to one hundred guineas were frequently given. One grazier some time since let rams to the amount of twelve hundred guineas; but the rage is now over, the people not being so foolish as to be duped out of their money, without the prospect of being repaid. It is here the practice with some to ride their ram lambs; but they are paid always to be injured in their growth, if not in their constitutions and dispositions, by it. When a ram dies while at ride, the lofs falls on the owner, and, besides, he is not paid for the riding. The time of paying is when the rams are removed from the ewes. This is done by carrying them away in carts, or leading them by ropes. The ram lambs are here now mostly selected and saved, in such numbers as are proper for the hirers.

Some time before the riding season, the graziers call and agree for the hiring or purchasing of rams, the general price usually from three to five guineas; but a superior one will bring ten in particular cases, though many good useful ones let at three guineas. Some purchase them to ride, and immediately afterwards sell them in the markets. The rams, which are to be hired, are here shewn all together in pasture fields, which is a disad vantagous method.

In Suffolk, until lately, ten guineas were the highest price that was heard of for the sale of any ram. Now some let many of their three-years old rams for fifty; and inferior ones at thirty, twenty, and ten guineas. Some have even been let to high as one hundred guineas.

RAM is also a term used to signify any thing which has a strong smell or tale.

RAM, in Astronomy. See ARIES.

RAM of M. Montgolfier, Hydraulics, in Mechanics, a machine for raising water to any given height, which has lately attracted much attention in France. The first person who employed this method was Mr. Whitehurt, and it was afterwards improved by Mr. Boulton. Its construction and use may be sufficiently understood by the following statement. It serves to raise water by means of the momentum of a stream of water flowing through a pipe. The passage of the pipe being stopped by a valve, which is raised by the stream, as soon as the rise is sufficiently rapid, the whole column of fluid must necessarily concentrate its action almost instantaneously on the valve, and in this manner it looses the characteristic property of hydraulic preasure, and acts as if it were a single solid; so that, supposing the pipe to be perfectly elastic and inextensible, the impulfe must overcome any preasure, however great, that might be opposed to it; and if the valve open into a pipe leading to an air-hole, a certain quantity of the water will be forced in, so as to condence the air, more or lefs rapidly, to the degree that may be required, for raising a portion of the water contained in it to any given height. Young's Course of Lectures on Nat. Philos. vol. 1.

RAM, in Mythology, the name of the highest god among the Gentoos. When a widow offered herself to be burnt on the funeral pile of her husband, she was encouraged by the presence of a number of attendants, who formed a circle around her, and offered her fire, to the end that she might salve the deceased friends, whom she might meet in the celestial abodes, in their names.

RAM, Battering. See ARIES.

RAM's Horns, in Purification, a name given by M. Belidor to the tenailles.

RAM-Head, on board a Ship, the name of a great block belonging to the fore and main halliards. It hath in it three hollows, into which the halliards are put, and at its head the eyes are receiv'd into a hole made there for that purpose.

RAM-Head, in Geography, a cape on the S. coast of Ireland, and county of Waterford; four miles E. of Youghal bay. N. lat. 51° 56'. W. long. 7° 44'.-Allo, a cape on the S.E. coast of New Holland, S. lat. 36° 56'. E. long. 119° 35'.-Allo, a cape of England, on the S. coast of Cornwall, in the English Channel, between Whitefhead and Plymouth found. N. lat. 50° 15'. W. long. 4° 12'.

RAM-Hornuz, a town of Perfia, in Chasfian; 69 miles S.E. of Sulfer or Shafter.-Allo, one of the most romantic vallies in Perfia, which has been lately placed under the beglerbeg of Behalan. It is fifteen furfurings in length (the furfuring being estimated at 32 English miles), and from fix to eight miles in breadth. The river Jeraki, entering at the easter extremity, flows through the centre of it, when meeting the Kkoorkhankende, which descends from the mountains six miles E. of the town of Ram-Hornuz, they together force a passage through a low ridge of hills, which skirt the valley to the south. This fertile spot is, at present, in the hands of five hoffle chiefs; the rift of whom is an Arab, who resides in a mean village, situated at the W. end of the valley, and built amidst the ruins of the ancient city of Ram-Hornuz. The remaining four are Persians, and brothers, who have each a castle, or fortified village; from which they make frequent forays, and carry off the corn and cattle of their rivals. A great battle was fought in this valley, between Atraxerses Babegan, and Arthabes, in which the former was victorious, and first alluded the title of "Shah en Shah," or king of kings. Kinneir's Peri. Emp. 1813.

RAM's island, an island in lough Neagh, Ireland, about two miles from the shore, and containing about fix acres.
acres. It is in the western part of the lough, in what is called Sandy bay, and is the only island. One of the round towers, so frequent in Ireland, is found here, and renders it an interesting object from the neighbouring grounds. Duboirdon's Antrim.

RAMA, or RAMLA, a town of Palestine, which was formerly large, and defended with strong walls; celebrated as the place where St. Paul cured Æneas. The Mussulmen reverence here the tomb of Loeman, the wife, and the sepulchres of seventy prophets, said to have been buried here. The church of St. George is the only object now worthy of notice. The place has a kind of market for gall-nuts, fena, and gum arabic, which the Arabs bring hither for sale; 20 miles N.W. of Jerusalem.

RAMA, a town of Dalmatia; 20 miles S.W. of Moltar.

RAMA, or Rama, signifying an eminence, in Scripture Geography, a town of Judea, in the tribe of Benjamin, according to the book of Joshua, ch. xviii. v. 20. It was situated towards the mountain of Ephraim, between Gaba and Babel, about seven miles from Jerusalem, according to St. Jerom. This city lay on the road from Samaria to Jerusalem; for which reason Baasha, king of Israel, called it to be fortified, to obstruct the passage from the land of Judah into that of Israel. This is the Ramatha, or Ramathaim-Zophim, the country of the prophet Samuel. (1 Sam. i. 19. and ii. 11. &c.) It was on the frontiers of Ephraim and Benjamin; and frontier cities were inhabited by both tribes. Jeremiah probably speaks of this Ramah.

Rama, a city of Naphtali (Joth. xix. 36.), on the frontier of Apher (Joth. xix. 29.)

Rama, in Hindoo Mythology, is the name of a distinguished mortal, in whom their deity Vishnu was incarnated for the purpose of relieving mankind from the tyranny and oppression of Ravana, the malignant king of Lanka, or Ceylon. This incarnation is one of the ten avatars, or descents of Vishnu, and is, in its supposed importance, second only to that of Krishna. It is similarly a popular history, and allusions to it perpetually occur in the writings and conversation of the Hindoos. The invasion and conquest of Lanka is the subject of one of their finest poems, entitled the Ramayana; it furnished subjects for the drama, for itinerant bards, and for every purpose of poetry, being replete with magnificent imagery, and abounding in striking incidents. (See Ramayana.) The mortal parents of this divine hero were Raja Dararth, king of Ayodetha (Oiide), and his first wife Kahunfliya. Hence this Rama is sometimes styled Darath Rama, to distinguish him from other heroic Ramas; and sometimes Rama Chandra, meaning of lunar descent.

There are three persons of the name of Rama, recorded as incarnations of Vishnu. One is Bala Rama, the elder brother, by the same parents, of Krishna; the second, Parash Rama; and the third, Rama Chandra, the subject more immediately of this article. But it has been made a question, whether they be not three representations of one person, or three different ways of relating the same history; and whether any or all of them mean Rama the son of Cuth, for W. Jones (Af. Ref. vol. i.) says he leaves others to determine. He deems Rama to be the name of the Grecian Dionysos, who is said to have conquered India with an army of faytrs, commanded by Pan; and Rama was also a mighty conqueror, and had an army of large monkeys or faytrs, commanded by Maruty, son of Pavan. (See Maruty.) Rama is also found, in other points, to resemble the Indian Bacchus: he is, notwithstanding his lunar appellation above noticed, fabled to be a descendant of the sun, his wife's name is Sita; and it is very remarkable that the Persians, whose Incas boasted of the fame of the, filmed their great festival Ramafita.

In a charge delivered by Dr. Watson, afterwards bishop of Landaff, to the clergy of the archdeaconry of Ely in May 1780, are many curious and shrewd observations on oriental usages. He notices a "ring of cumbans wholly the fame amongst people so far removed from each other as the Egyptians and Persians. The Egyptian women, he says, made faced cakes of flour, which they offered to the queen of heaven, at their principal solar festivals called Raymi and Citua: the Persian women did the same." Almost all the cumbans described as common to these distant people, the Egyptians and Persians, as well as that quoted, are Hindoo cumbans, ancient and extending.

All the Ramas are famed as great warriors and as youths of perfect beauty. In the Gita, an episode of the Mahabarat, Krishna, describing himself to Arjuna as pre-eminent among all things and persons, says, "Among those who carry arms, I am Rama." It is Rama Chandra, however, and his lovely Sita, who are the favourite subjects of heroic and amatory poets: he is described in the Ramayana as of ample shoulders; brawny arms, extending to the knee; neck shell-formed; chief circular and full, with auspicious marks; body haunchthine, with eyes and lips of sanguine hue; the lord of the world; a moiety of Vishnu himself, the source of joy to Ikhwau's race." He is suitably rated in his faithful Sita, one of the most interesting females in Hindoo poetry. (See under her name for some account of her, and a description of her person.) Rama is also called Raghu, or son of Rafta, (see these articles,) like Ikhwau, one of his mortal ancestry. Kaka-paksha-dara, or crow-winged, is an epithet given to the Ramas, and to other warriors, from a certain mode of having the head, leaving the hair over the ears only, resembling crow's wings, as is fancied. Shyamula, or blue-bodied, is an appellation of Rama, as well as of Krishna, and of their common prototype, Vishnu; all being represented of haunchthine hue. It may be here remarked, that several incidents in the Sri-Bhagavat, a history of Krishna,) and in the Ramayana, told similarly of their several heroes, seem to mix or approximate, though perhaps fearfully to identify, the characters of Krishna and Rama. Each won a wife by bending an unyielding bow, not very unlike the ivory of Ulysses. Each is described as overcoming the demons, Kumbakama, and others. Krishna defended into hell; so did Sita, the fact, or energy of Rama. Both have adventures with the bear Jamba. See Jamba, &c.

All sects and tribes, who, under the denomination of Vajishvaras (which see), worship Vishnu, (bating such deistical philosophers as sceptically deny the personal existence of inferior deities, attributes, or avatars, of whom see under Jaimini), agree in stating, that, with the exception of Krishna, the potentiality of the preferring power was never exhibited in such plenitude as in the avatar of Rama. In popularity, and in dramatic, historic, and poetic shapes, it rivals that of Krishna. And as one or more sects adore Krishna as the deity himself, and draw rules for their religious and moral conduct from the Sri-Bhagavat; so the sect called Ramanuj similarly clothe Rama in almighty attributes, and deem the Ramayana a complete body of ethics and morality. See Ramanuj.

In the series of incarnations of Vishnu, called das-avatara, or the ten avatars, to distinguish them from others of less importance, the avatars of Parash Rama and Rama Chandra are usually placed sixth and seventh, as given under Vishnu. Sometimes Krishna is altogether omitted; in which case,
Bala Rama ranks as the eighth. *Mujah* is a name of the third Rama, under which word some notice is taken of him. And of *Paruyr* or Parinya Rama, see under that article. The name of Rama, or perhaps more correctly of Rami, is one of the many names of Parvati, confron of Siva. The name is also used, beyond the pale of his own sectaries, in supplication and prayer. Ram-Ram is a usual salutation, like our good morrow, between friends at meeting or parting, and is used by both Vaishnavas and Saivas; and it is reverently reiter-ated in times, and in aid, of abrashion (see Jap); and under the operation of feelings of enthusiasm or dittresses.

The history of the Ramas mixes itself with that of so many others of Hindoo mythological persons, that in many of our accounts of such persons, &c. particulars occur respecting them. Thole deferreds of further notice of the Ramas are, therefore, referred, in addition, to the following articles: *Ceylon*, *Java*, *Kahunslya*, *Lakshman*, *Lanka*, *Maruty*, *Ravena*, *Ramayana*, *Runeke*, *Sita*, &c. from which other references point to articles on subjects connected herewith.

*RAMADA*, or *Nem Salamancn*, in *Geography*, a town of South America, in the province of St. Martha; 50 miles E. of St. Martha. N. lat. 11° 40'. W. long. 72° 20'.

*RAMADAN*, a fort of lent observed by the Mahometans, in obedience to the express command of the Koran, during which they fast the whole day, from the time the new moon first appears, till the appearance of the next new moon, with such extreme superstitition, that they neither eat, drink, or sleep, but dare not walk their mouth, nor even swallow their spit, from day-break till night, or sun-set.

The men, indeed, are allowed to bathe themselves; but it is on condition they do not plunge the head under water, lest some drops enter by the mouth or ears, &c. But as for the women they are strictly forbidden bathing. Some are so cautious, that they will not open their mouth, to speak, lest they should breathe the air too freely. The fast is also deemed void if they kiss or touch a woman. To make amends, they feast all night till day-break; though the more rigid begin the fast again at midnight; and usually spend more in this month than in six others.

The Ramadan happens at different feasons of the year; and when it is in the summer it is very hard on the labourers. This month once in thirty-three years is in every leason of the year, the Turkish month being hunar, and they beginning at the day they can see the moon; whereas the Jews begin their account from the day the moon makes, which is a day before the Turks.

The reason given why the month of Ramadan was fixed upon for this purpose is, that on this month the Koran was sent down from heaven. From this fast of Ramadan none are excused, except travellers and sick persons, under which latter denomination are included all those whose health would be manifestly injured by keeping the fast; but then they are obliged, so soon as the impediment is removed, to fast an equal number of other days; and breaking of the fast is ordered to be expiated by giving alms to the poor.

*RAMAG*, a word used by some of the chemical writers to express alive.

*RAMAGE*, a term used for the boughs or branches of trees. Hence: *Ramage-Hawk*, or *Falcon*, one that is wild and coy, as having been long among the boughs, preying for itself. All falcons retain this name till they have left the very; being so called in May, June, July, and August. They are very rarely reclaimed. *See Brancher*, *Falcon*, and *Hawking*.

*RAMAGE Velvet*. *See Velvet*.

*RAMAGURRY*, in *Geography*, a town of Hindoothan, in the Carnatic; 30 miles W. of Trichinopoly.

*RAMAH*, a town of Arabia, in the province of Neds-jed; 120 miles N.W. of Jamama.

*RAMAH*, or *Ramalla*, *Ramola*, *Ramula*, *Ramba*, or *Rumphius*, a city W. of Jerufalem, between Lydda and Joppa, according to St. Jerome; or between Joppa and Jerufalem, as modern travellers describe it. This is the place which Eufebius and St. Jerome took for Arimathea, the country of Joseph. *Matt. xxvii. 57*.

*RAMAI*, in *Natural History*, a name given by many old writers to bole armenic.

*RAMAK*, in *Ichthyology*, a species of *Sciens*; which see.

*RAMALINGA*, in *Geography*, a town of Hindoothan, in Coimbero; 16 miles S.S.W. of Erroad.

*RAMALIS VEXA*, a name given by some anatomical authors to the vena porta.

*RAMANUJ*, the name of a religious sect of Hindoos, of the great subdivision of Vaishnava, who worship Vishnu, the personification of the preferring power of the deity, in his incarnation of Rama. Of this sect some worship Rama only, some his spouse Sita, and some both Rama and Sita conjointly. *See Rama.* Among the Ramayun none are addicted to the indecent, or left-handed, mode of worship noticed under the article *Radias* as disgracing her votaries. *See further under Saka*, and *Sects of Hindoos.* The different sects of Hindoos are distinguished by a variety of marks on their foreheads; of which a great many are represented in the second plate, with copious explanations in page 424, of the Hindu Pantheon. The sect of Ramayun are known by a double upright white line on the forehead, with a red line between, or sometimes a circlet or dot. Sometimes the lines are red and the circlet black.

*RAMAS*, *Cape*, in *Geography*, a cape on the W. coast of Hindoothan; 21 miles S. of Goa.

*RAMASSERAM*, a town of Hindoothan, in the cir-ecar of Rajamundry; 35 miles S.S.E. of Rajamundry.

*RAMAYANA*, the title of a poem in the Sanscrit language, of great celebrity in India, and regarded as sacred by some sects of Hindoos, and greatly venerated by all. Its subject is the exploits of three persons named Rama; but more especially the wars conducted by one of them, named Rama Chandra, for the conquest of Lanka or Ceylon, from its powerful sovereign Ravena, or rather, indeed, for the rescue of his wife from the hands of that tyrant. It is comprised in seven kandas, or books, containing 24,000 lines, or metrical stanzas; named thus: 1. Adi-kanda, containing 64 stanzas, and 2850 flanzas; 2. Ayodhya-kanda, 80 stanzas, and 4170 flanzas; 3. Aranyaka-kanda, 114 stanzas, and 4150 flanzas; 4. Kehinda-kanda, 64 stanzas, 2925 flanzas; 5. Sundara-kanda, 43 stanzas, 2045 lines; 6. Yudha-kanda, 105 stanzas, 4500 flanzas; 7. Uttara-kanda, 90 stanzas, 3360 flanzas. The Ramayana may be called an epic poem, as it is on one contin-ued, interesting, and heroic action. It is second in celebrity only to the Mahabarat, and perhaps superior to it in reputation for holiness. *See Mahabarat.*

We have the au-thority for William Jones, that *this great epic poem, in unity of action, magnificence of imagery, and elegance of diction, far surpafls the elaborate work of Nonnes, in forty-eight books, entitled Dionysius; and for believing that the heroes of the poems Rama (paternally distinguished by the name of Dafrat Rama) and Dionysos are the same.*
A curious parallel might be drawn between the manners and customs described in these two works, the Dionysiac and Ramayana. The proceedings and rites detailed in the former seem defective, with a little licence for poetical embellishment, of those in use to this day in India. Some of these Bacchic orgia are noticed under our articles Dionysia and Nonnus; which see. A keen etymologist would find innumerable linguistic coincidences; and, in truth, many of the names of perfons, Bacchus and Dionysos, and of places, as well as original perfons, seem soberly traceable to the sacred language and rites of the Brahmins.

So highly is the Ramayana venerated, that the fourth clas of Hindoos, the Sudra, is not permitted to read it. At the end of the first book, a promise is made of great benefit to any individual of the three first classes or tribes who shall duly read it. "A Brahman, reading it, acquires learning and eloquence; a Kshatriya will become a monarch; a Vaisya will obtain vast commercial profits; and a Sudra, bearing it, will become great." Of these distinctions of tribes or classes, the reader will find due notice under Sects of Hindoos. Under Rama we have stated that his name reiterated is used by several lexets as a sort of salutation, or benediction. The author of the Ramayana, in the vanity of playful egotism, which, from its frequency with oriental poets, has ceased to seem affuming, calls on his readers to "salue Valmiky, the kukila (cuckoo), who, mounted on the branch of poetry, founds the delightful note of Rama-Ram.

It has been furnished that the Ramayana, like the Mahabharat, is allegorical, so far as relates to personal adventures; which, in both cases, are mere machinery for the introduction of a concealed sytem of philosophy and ethics: in the first instance the allegory is physical, in the latter moral. Under the article Mahabharat the allegorical nature of that extraordinary poem is sufficiently shown. The Kuras and Pandus, the heroes of that poem (see Kuru and Pandu), are perfonifications of virtues and vices. The Ramayana and the Dionysiac relate how their respective Indian conquerors led armies of satyrs. (See hereon under Mahabharat and Ramayana.) These satyrs, or monks, we apprehend to be perfonifications of winds, or gaseous meteors. In the Ramayana we find the machinery to confit of the sun and planets, fire, the firmament, wind, water, &c. perfonified in the gods or regents of those bodies, elements, &c. It has been farther furnished us, that whenever these two extraordinary poems, the Mahabharat and Ramayana, shall appear in English, and their allegories be more fully examined, it may possibly be found, that not only the three Ramas will melt into one, but that all will amalgamate with Krihna. Some objections to the identity of the Ramas have been offered of a chronological nature. Parasu Rama, it is contended, reigned or flourished eight generations before Rama Chandra. Their poetical identity, however, is sufficiently established; and one can scarcely bring such a tiffue of allegory, incantations, and whimsical adventures, to the test of sober historical and chronological accuracy. Perfons of these names may have reigned or flourished at any given period, for they have always been very common, and are so still.

The Ramayana is so replete with incident, that it is scarcely possible to give any analysis of its subject with sufficient brevity for this work. Unity of action is, however, its characteristic, namely, the recovery of Sita from the hands of her ravishe Ravena, the gigantic tyrant of Ceylon. It may be noticed in passing, that the Ramayana, like the Iliad, is founded on a rape, and that Sita is the Helen of the Hindoo epic. (See Sita.) So inerably intermixed are the varied subjects of the Hindoo mythological history, that the discussion of one necessarily brings another under notice. This is the cause of such frequent references to and from the articles under which we have endeavoured to give a succinct account of such a number of subjects of that description, distinct apparently, but in reality connected, and often confounded with each other. On the subject of this article, the Ramayana, or for quotations from it, we may therefore refer to the following, among others: Ceylon, Lakshmi, Lanka, Maha, Parasu Rama, Menaka, Ravana, Khemb, in addition to those pointed to in earlier passages of this article, and in those articles just named.

What precedes, referring to the poem bearing the title of this article, is offered respecting the Ramayana of Valmiki. There are many other poems of the same name in Sanscrit, Prakrit, Hindvi, and many other Hindoo dialects; as well as in Arabic, Persian, Malayen, and others derived from the like source. These are of course of unequal celebrity and merit; and acknowledged to be greatly dillerent from Valmiki's divine poem. Even of this it may be said, that the style is frequently flat and diffuse, deficient in ornament, and abundant in repetitions. As well as Valmiki's work, several others, under the same title, are usually considered with more respect than mere profane poems. One is ascribed to Vyasa, the reputed author or compiler of the Vedas and Puranas. (See these articles.) A considerable portion of several of the latter mythological romances is occupied by the same subject, to wit, the adventures of Rama; but in the Vedas no mention is made of this person, except, indeed, in some detached parts, reasonably suspected to have been interpolated by zealous sectaries. The titles even of the philosophical and profane poems, commentaries, &c., that in divers languages owe their origin to the Ramayana, would require a catalogue of no inconsiderable extent to contain them. Among these are included many dramatic works. The quotations from, and allusions to its mythological personages and fables, in the works of the minor poets, are incessant; and upon the whole, there is no subject, perhaps, in the whole range of Hindoo mythology, or history, so often in the minds and mouths of that race of all ranks and sects, as the story of the Ramayana in some of its bearings. That of Krihna rivals it in popularity. Both are chanted by itinerant bards, who illustrate their subjects by exhibiting a series of pictures from the Ramayana and Mahabharat. Women fingers frequently accompany these eastern troubadours, who are commonly met with in every city, camp, and town of India.

RAMAZZINI, Bernardin, in Biography, an Italian physician of distinction, was born at Carpi, near Modena, in 1633, where his father was a respectable citizen. Having received a classical education at the Jesuits at his native town, he went to Parma for the study of philosophy at the age of 19, undecided what profession to adopt; at the end of three years he selected that of physic, and received the degree of doctor at Parma in the beginning of 1659. He then repaired to Rome for the completion of his studies, and settled in practice in the duchy of Castr. He was soon obliged by ill health, however, to return to his native air; and, on his recovery, he married, and pursued his profession at Carpi. Finding his reputation increasing, he removed to Modena, at the solicitation of some friends, in 1671, where he met with merited successe, and excelled the jealousies of his brethren. In 1682 he was appointed professor of the theory of medicine in the university, which had been recently establisht at Modena, by duke Francis II.; and he continued to fill this office for eighteen years, attending at the same time to practice, and not neglecting the cultivation of polite literature, to which he was particularly partial. The
...
tually discovers himself to be a great harmonist; but inured to a bad taste and style of composition, as well as to bad singing, he has only augmented the defects of his predecessors, and rendered what was rude and clumsy in Lulli still more offensive, by endeavours at sweetness or high coloring. The appoggiaturas, or leaning notes, being so frequently incorporated in the harmony, renders it crude, and the hanging on every note, as if unwilling to relinquish it, checks and impedes the motion of the air, and gives it a flow and languid effect, however lively the theme on which it is composed. Every passage in such melody resembles a French heroic verse:

"Each is an Alexandrine, through the song,
That, like a wounded snake, drags its flow length along."

The opening of the second act, "Que tout gemisse," is very fine, and the pathos well applied; but the sub frequent air, which is cast in an admirable mould, is spoiled by frequent and unnecessary changes of measure; and yet in spite of these defects, and the vocal outbursts of mademoiselle Arnould, we were more pleased and affected by this scene, than any other we ever heard at the French serious opera. The march, which has few appoggiaturas in it, is like other Christian music.

The prelude tender, at the opening of the third act, abounds with too many of these drags, which being equally harsh to the ear and injurious to pulfation, seem to prevent the performer from ever falling on his feet; and in the eleventh, the chord of the superlative fifth, which makes all nature shudder, except our Gallic neighbours, is here continued so long, that it disfigures the countenance of every other hearer, like his paam. The major minuet, page 121, after so long and tiresome a minority, is rich in harmony and graceful in melody. The voice is wont used by the composer than the most insignificant instrument. For after several symphonies that are extremely promising, and the ear has been made to expect a continuation of the prelatory strain, nothing is given to the vocal part but broken accents and dislocated measures. In the chaconne, which is admirable, the measure is well marked and well accentuated. This muft long have preceded Jomelli's favourite chaconne, and have served as a model to him, Theller, and others, in composing this species of dance. More genius and invention appear in the dances of Rameau than elsewhere, because in them, there is a necessity for motion, measure, and symmetry of phrase. And it may with truth be said, that nothing in Lulli's operas was imitated or adopted by the rest of Europe, but the style of his overtures, or in Rameau's, but the dances.

But though the several merits of this musician have been too much magnified by partisans and patriots in France, and too much depreciated by the abettors of other systems and other styles, as well as patriots of other countries, yet Rameau was a great man; nor can the professor of any art or science mount to the summit of fame, and be elected by his countrymen supreme dictator in his particular faculty, without a large portion of genius and abilities.

The successful revival of his opera of "Caflor and Pol- luex" in 1754, after the victory obtained by his friends over the Italian burletta fingers who had raised such disturbance by their performance of Pergolesi's intermezzo, the "Serva Padrona," was regarded as the most glorious event of his life. The partizans for the national honour could never hear it often enough. "This beautiful opera," says M. de la Borde, "without any diminution in the applause or pleasure of the audience, supported a hundred representations, charming at once the soul, heart, mind, eyes, ears, and imagination of all Paris."

From this era to the time of his death, in 1767, at eighty- four years of age, Rameau's glory was complete. The Royal Academy of Music, who all regarded themselves as his partizans, performed a solemn service in the church of the Oratory, at his funeral. And M. Philidor had a mass performed at the church of the Carmelites, in honour of a man whose talents he so much revered. See Base, BAISE Fondamentales, and Counterpoint.

RAME, a name given by some chemical writers to march.
RAMEX, (ramus, a branch,) in Surgery, a rupture, or hernia. See Hernia.

RAMEX PECTORIS. See Circumflex.

RAMGAD, in Geography, a town of Hindostan, in Bahar: 10 miles W. of Bahar.

RAMGARY, in Geography, a town of Hindostan, in the country of the Naws: 15 miles W.N.W. of Pahalscherry.

RAMGURT, in Geography, a town of Hindostan, in the sibah of Delhi: 15 miles S.E. of Secundera.

RAMGETT, in Rural Economy, a term applied by the husband breeder to such rams as are proper for getting ram-stock, in contradistinction to such as are fit only for getting ewe-stock. See Ram.

RAMGONGA, in Geography, a river of Asia, which rises in Tibet, and runs into the Ganges: 10 miles N. of Calcutta.

RAMGOT, a town of Hindostan, in Concan: 15 miles N. of Goa.

RAMGUR, a circuit of Bengal, bounded on the N. by Bahar, on the N.E. by Curranchta, on the S. by Patna, and on the W. by Koonda and Torre: about 66 miles long, and 60 broad. Also, the capital of this circuit: 135 miles W.N.W. of Calcutta. N. lat. 29° 49'. E. long. 83° 41'. Also, a town of Hindostan, in Koonat: 55 miles S. of Neemur. N. lat. 18° 38'. E. long. 79° 11'. Also, a town of Hindostan, in Malwa: 8 miles S. of Rigoopur. Also, a town of Hindostan, in the sibah of Delhi: 5 miles N. of Coel.

RAMGURRA, a town of Hindostan, in the Mylare, captured by the English in 1791: 43 miles N.E. of Seringapatam.

RAMHYTTE, a town of Sweden, in Vettemarkland: 12 miles from Stockholm.

RAMI, in Hindu Mythology, one of the many names of the goddess Parvati, which fest. Under this name she is said to be worshipped at the splendid temple on the island called Ramiferam, between Ceylon and the Cape named by us Comorin, but which should be called Cape Kamari, or Kurnam, another of the names of this goddess, and meaning the virgin. (On this point see Lanka and Parvati.) Ram is the name of a tree or wood sacred to Parvati, and the priest, sometimes called Sam Ram: it has been supposed that this is the origin of the term Rams in the Greeks. (See Heron, Act. Red. vol. IV. p. 392, vol. VIII. p. 186. Svo, ed.) A description of the celebrated temple of Ramiferam will be found under that article. See also Sami.

RAMJAVENPOUR, in Geography, a fort of Bengal: 27 miles S.S.W. of Burdwan.

RAMIFICATION, the production of buds or branches, or of figures resembling branches.

RAMIFICATIONS, in Anatomy, are the divisions of the arteries, veins, and nerves, arising from some common trunk.

RAMIGRI, a word used by some writers as a name for scoliosis.

RAMILLIES, in Geography, a village of France, in the department of the Sambre et Meuse, at the source of the river Grez; worthy of being recorded on account of a battle fought here in the year 1666, between the allies commanded by the Duke of Marlborough, and the French under Marshal Villeroie. The confederates took the whole of the enemy's baggage and artillery, and about 120 standards, 600 officers, and 6000 private soldiers; about 5000 were killed or wounded. The loss of the allies did not exceed 3000 men: 13 miles N. of Namur.

RAMING, a town of Austria; 11 miles S. of Steyr.—Also, a town of Persia, in the province of Isfah: 40 miles E. of Coniar.

RAMINGAM, a town of Hindostan, in Dowlatabad: 10 miles N. of Oddighur.

RAMINGSFORD, a town of Austria; two miles E. of Steyr.

RAMINGUE, in the Marches. A horse gets this name that derives, and retains its name from the spurs; that is, the horse is named after the spur. Sometimes called the remus, and frequently worthy to favour his disobedience. See Ticklish and Double.

RAMIS, BARTOLOMEO, in Biography, a Spaniard, the first modern who furnished the necessity of a temperament in musical instruments, of which the tones are fixed. He was contemporary with Franchinus, and in 1482 published a work, entitled "De Musica, Tractatus, sive Musica Practica."

He seems to have converted Pietro Aaron to his opinion: as that theorist manifestly exalts the character of Ramis on all occasions at the expense of Franchinus. The Spaniard was attacked in a rough manner by Nicholas Burtius, for differing from Guido in his division of the monochord, in a tract entitled "Musices Opusculum cum Defendis, Guidonis Artini adversus quendam Hilipanum verisimilis praevaricator." Berton. 1487. This tract, printed in black letter, is in the Ashmol. Collects, among the books of Art. Wood.

Burtius imagined the honour of Guido to be injured by the Spaniard, as Guido used the Pythagorean proportions, and had never thought of a temperament. Burtius, in his turn, was handled very roughly by Sartaro, the disciple of Ramis (Joannes Spadarius Bononiensis, Musaeus at Bartolomii Ram. Paulo ejus Præceptoris honesta Defenso in Nicol. Burtij Parment. Opcis. Bolognas, 1491.); and the venerable Francinus, finding himself very rude did in the dispute by the favours of temperament, in 1522, when he was upwards of seventy years of age, took up the defence of Pythagoras, as Fontenelle, at near a hundred, did of Des Cartes. After this, the war became general, and continued to rage with great violence for more than a century, between the friends of tempered scales, and the adherents of ancient proportions and equal harmonies.

RAMISERAM, in Geography, an island in the Indian seas, between the island of Ceylon and the coast of Coromandel; to which there is a passage of about 12 or 14 leagues from the island of Manar, on the coast of Ceylon. But the advantages that might be derived from this speedy communication are in a great measure prevented by the numberless shallows and sand-banks, which every where interrupt the passage, and which are so high, that many of them are dry except during the monsoons. There is in particular a line of sand-banks, which runs quite across from Manar to Ramiferam, designated Adam's bridge, and also Rama's bridge, because it is said to have been by this way Ceylon. (See Adam's Bridge and Manar.) From Ram, Ramiferam takes its name, and it has a large temple dedicated to him. The shortness of the passage from Ramiferam to Manar is particularly useful on account of the speed of conveyance it affords to people on business, and the communication of intelligence. The messengers who usually go from Colombo to Manar, a distance of 160 miles, in three days, take boat here, and continue by Adam's bridge to Ramiferam, and then proceed along the Coromandel coast to Madras. An express
express in favourable weather will run from Colombo to Madras in eight days, and the journey has been accomplished once in seven days. (See Manaar.) The isle of Ramifieram, which is the limit of the Hindoo religion in more modern times, and of the conquests of the Mooliman princes, is, as we have said, separated from Ceylon by Adam's bridge. The isle is low, sandy, and uncultivated, except with a few clustered Palmira and cocoa-trees. The pagodas, for which it is so famous, lies on the Ceylon side, near the sea, and are the resort of innumerable multitudes of different sects of religion in India, during the feason of certain festivals. The numerous pagodas are constructed in the same style with those on the Coromandel coast; and they are surrounded with the houses of the brahmins, priests, and other religious persons, whose zeal leads them to attend on their temples; among whom, in particular, may be seen the descendants of the Tamul, Telingas, Canarians, Mahtrattas, and Orias, who compose a great body of the original inhabitants of the southern peninsula. Their houses are built of the cocoa-tree, in small squares and streets, where their families are seen reclining on the little mud terraces, and under the payals or virandas. They do not allow Europeans to enter these temples; but they are known to resemble those of the coast in their crowded ornaments, spires of brickwork, long porches in front, and halls, at the extreme end of which are placed the deities, in an obscure situation, surrounded by lamps burning day and night. The same service to deities subsists among all the southern brahmins. The brahmins allow no labour or cultivation to be carried on in the island of Ramiferam, considering it altogether as sacred. The contributions of those who visit it are sufficient for the support of the temples. Several of the neighbouring Poligar chiefs contribute largely, and some of these rajahs have statues erected to them for their gifts. The chief pagoda has several of these statues in its different squares. Low as the land lies in this isle, good water is easily procured; for on sweeping it up, the water collects immediately in the holes; but this is not the case in Manara and the west coast of Ceylon. The guardianship of this sacred isle belongs to a family of devotees, called "Byragees," the chief of whom is always doomed to celibacy: the succession being carried on by the fillers or the collateral branch, who only are permitted to marry. This institution is similar to that of the sovereignty of the Travancorians and Nairs of the Malabar coast. The clothes and turbans of the devotees are of a tawny red colour, decorated with large black beads, of a particular kind of wood. From the pagodas just mentioned there runs out a long narrow piece of land, terminating in a point, within a mile of which is a choultry at Tonn Goody. This is a square of houses with a court inclosed for the accommodation of pilgrims, who come to the farthest point of the islet to perform their ablutions in the sea, most sacred and the purest of their ceremonies. A brahmin takes care of this choultry, and a pole with a light is fixed at the end of the point to direct the pilgrim. N. lat. 9° 18'. E. long. 70° 22'. Percival's Ceylon.

Of the temple in this islet we shall give some account, extracted from a publication of Mr. Cordiner, who visited it. The external appearance is not remarkably grand, and at a distance, no idea is excited of the minute ornaments and labourd workmanship which strike the eye on a nearer inspection. All the architecture seen without doors is insignificant, compared with the magnificence of the interior. After an examination of the whole structure, which is entirely of hewn stone, Mr. C. deemed the extent of masonic labour in its erection, must have been equal to that of any of the most splendid cathedrals of Europe. "On entering it we were," he says, "completely astonished at the grandeur of the workmanship, and extent of the dimensions, which far surpassed any idea that we had formed of Indian magnificence." From the well gate a low gallery, 144 feet in length, with three rows of pillars on each side, leads down to the centre of the building; where it branches off, in galleries similarly constructed, to the right and left, each extending 150 feet, then running from west to east 520 feet, and enclosing an oblong rectangular space. The gallery runs also along the centre of the temple 788 feet, and a similar gallery runs around from north to south, where are like entrances, intersecting the former in the centre of the rectangular space. All the galleries have on each side triple rows of lofty stone pillars, of highly laboured workmanship. Thrice in the front line are the largest and most superb, having a huge base, with the mouth wide open, sculptured in bas relief, above three distinct capitals, over which are a scroll, and a richly ornamented cornice. Statues of the size of life are attached to many of the pillars, representing gods and deified persons. The pillars stand on a continued basement, forming the floor of the galleries, raised three feet, with steps to ascend by, all of stone. The roofs of all the galleries are flat, formed of stones reaching across, from the projection of one cornice to that of the other. The galleries are eighteen feet wide, and in the centre thirty feet high from the floor. The number of pillars within the temple amounts to 2625. The edifice is inclosed by a heavy stone wall, 20 feet high, 830 feet from east to west, and 615 from north to south. Large as these dimensions may appear, they are stated to be but small compared with those of temples on the continent of India, one of which covers a square mile of ground. The covered gallery, fronting the south gate, which seems unfinished, strikingly resembles the entrance of the Elephanta cavern, near Bombay. Solid pyramidal erections surmount the western and eastern entrances, composed externally of a great number of small pillars, two and two, in the form of window frames or gateways, rising one above another, in seven different stories. That over the western, which is the principal entrance, appears to be 150 feet high; the eastern seems lower, and unfinished. The north and south gates are left as majestic as the others; but their completion is laid to be intended, when they will be similarly surmounted and ornamented as the western portal. Privileged persons, among whom were women carrying water-pitches, appeared constantly passing and re-passing about the interior of the temple. Two hundred Brahmins are attached to this temple, and supported in ease and luxury by its endowments. It is dedicated to Siva, the destroying power, called by the vulgar Rama Lingang. It contains likewise, Mr. Cordiner says, images of Vishnu the preserver, and of all the subordinate divinities. Of Brahma, the creator, he states, the Hindoos never dare to form any likeness. This is a common error, that is explained and corrected in the article Idolatry of this work.

A broad street runs parallel to each side of the temple composed of comfortable houses, and large choultries for the accommodation of pilgrims and travellers, of stone, with flat roofs supported in front by pillars; the fronts being open. In one of these Mr. Cordiner observed two ivory palankeens inlaid with gold, the property of officers belonging to the sanctuary. In others he noticed five carriages, called by the English Swamy coaches, used for the purposes of carrying the idols in procession: the use to which the ivory palankeens are, we apprehend, also applied.

These
These carriages are described as solid masses of wood, of a pyramidal shape, intended to symbolize the Linga. (See Linga.) The exterior of their coaches are covered with grossly obscene carving.

At the external corners of the temple, and in the streets of the town, there are smaller temples in honour of different deities, and containing images. In some of the streets spreading trees, among them the sacred religiosa and tamarind, are surrounded with square stone terraces, on which are placed little images of Pollecar or Ganada. (see Pollecar,) the Linga, two serpents entwined, and other emblems of Hindoo mythology. These terraces are used for contemplation, or more active religious duties, as noticed under the article Pradakshina. Rows of fruit-trees, among them the cocoa-nut, plantain, and pomegranate, stand in gardens beyond the north and south walls of the temple.

On the opposite side of the island, near the sea, distant about eight miles from the temple, is the ancient fort and choultry of Pombom. The road between is very elegantly paved with smooth slates, each six feet by four; and the greater part of the road is nobly shaded by the mould beautiful and majestic trees. The larger trees of this superb avenue are surrounded by smooth raised terraces of masonry, on which travellers rest in comfort, completely shaded. About half way between the grand temple and Pombom is a very elegant small temple, built on the same general plan with the larger, having two masonry towers raised in the centre of the oblong area, and a covered walk, with three rows of pillars on each side, all round. The outside of the towers is completely covered with statues in miniature, representing all the variety of their mythological divinities. The choultry, for the accommodation of pilgrims and travellers at Pombom, has two fronts, and three inlaid squares; and is surrounded by piazzas raised several feet, with square pillars and terraced roofs. Contiguous is a small temple, the door of which was open, displaying an image of Ganada or Pollecar, in the usual form, elephant-headed and pot-bellied, ornamented with necklaces of flowers.

There are several other elegant temples on this interesting island, which is entirely dedicated to the purposes of religion. No plough is allowed to break the soil, and no animal, wild or tame, is ever killed on it.

Dancing girls, mountebanks, and beggars, abound here, as in other referts of the idle and wealthy.

The small remains of antiquity still extant on Ceylon, sufficiently prove that similar religious institutions did once exist there, and that choultrys and temples were erected at the different places, all the way from Manaar through the island, 200 miles, to Dondra, its southern extremity, and the ultimate extent of Hindoo pilgrimage. At the latter place, the ruins of a temple dedicated to Siva are still to be recognized; but only some rows of scattered pillars, and a few remnants of broken images, have survived the fanatic fury of the early European invaders. Rama's peaceful island falling under the protection of a more liberal and enlightened government, fortunately escaped these religious tempelfs, which spread destruction round the coasts of Ceylon.

Lord Valentia has more recently visited this interesting scene, and Mr. Salt, who accompanied his lordship, has published a very elegant view of the temple. The entrance is described to be through a gateway, about 100 feet high, covered with carved work to the summit. The door is 60 feet high, composed of single stones placed perpendicularly, with others crossing. This massive workmanship reminded lord Valentia of the ruins of Egyptian architecture. He describes the quadrangle to be about 500 feet each side, and says that, on the whole, this temple is the finest piece of architecture that he had seen in the east. Words, he says, cannot describe its magnificence. The concourse of pilgrims is very great, and brings in a large sum; each paying according to his rank. The raja of Tanjore had been expected the year before, but could not afford it; and in presents and various expenses, it was estimated that his highness could not have performed this act of devotion under 60,000 pagodas, about 25,000l. sterling. His whole family would of course have expected to participate in the happiness and benefits of the pilgrimage. The idol udes no water but what is brought from the Ganges by fakirs: with this it is bathed every morning; and this holy water, thus acquiring additional sanctity, is fought and purchased by the devout for fin-expelling purposes.

RAMIST, in the History of Learning, the disciples of Peter Ramus, who was born in a small village in Picardy, in 1515, and from being a servant in the college of Navarre at Paris, became, by his talents, industry, and perseverance, one of the most famous professors of the sixteenth century. By attacking the authority of Aristole, and attempting to substitute in the place of his logic a method of reasoning better adapted to the use of rhetoric and improvement of eloquence, he excited a terrible uproar in the Gallic schools; so that the two bills books he published, viz. “Institutiones Dialeticæ,” and “Aristotelice Animadversiones,” were prohibited through the kingdom of France, and the author prohibited from any more teaching philosophy. His enemies perverted him with lampoons and satires, and even held him up to public ridicule on the stage. However, Ramus afterwards recovered his credit, so that he obtained the royal professorship of philosophy and eloquence, and afterwards of mathematics, at Paris, in 1547. But his enemies were ineretate in their persecution of him, and as soon as it was known that he favoured the party of the Hugonots, he was obliged once again to withdraw himself from the effects of their resentment. In the intervals of peace, he returned to his flation; but in 1568, when the civil war was a third time renewed, he resolved to leave France, and make a tour through Germany. After spending three years in visiting the principal German universities, and receiving many tokens of respect, he resolved, for his own country. Accordingly he settled at Paris, where he perished in the massacre on St. Bartholomew's day. On the tumult of this execrable day, Charpenteire, professor of mathematics, who had been eclipsed by the superior talents of Ramus, seized the opportunity of being revenged upon his rival, and, under the pretence of religion, employed assassins to murder him. His body was afterwards thrown into the street to the enraged pupils of Charpenteire, who dragged it ignominiously along the streets, and then cast it into the Seine.

The disciples of Ramus, such was the alienating influence of their master's learning and character, prevailed so far as to banish the Peripatetic philosophy from several feminaries of learning, and to substitute in its place the system of their master, which was of a more practical kind, and better adapted to the purposes of life.

Although he had considerable merit in exposing the defects and inconveniences of the Aristotelian philosophy, he does not seem to have been equally successful in his attempt to establish a new logical institute. The general outline of his plan is as follows. Considering dialectics as the art of deducing conclusions from premises, he endeavours to improve this art, by uniting it with that of rhetoric. Of the several branches of rhetoric he considers invention and disposition
position as belonging equally to logic. Following chiefly the example of Cicero, he divides his treatise on Dialectics into two parts; the first of which treats of the invention of arguments, the second of judgments. Arguments he derives not only from what the Aristotelians call middle terms, but from any kind of propositions, which, connected with another, may serve to prove any affirion. Of these he enumerates various kinds. Judgments he divides into axioms, or self-evident propositions, and "dianoia," or deductions by means of a series of arguments. Both these he divides into various classes; and illustrates the whole by examples from the ancient orators and poets.

In the logic of Ramus, many things are borrowed from Aristotle, and only appear under new names; and many others are derived from other Greek sources, and particularly from the dialogues of Plato, and the logic of the Stoics. Whilsf the author has the merit of turning the art of reasoning from the futile speculations of the schools to forensic and common use, his plan is defective in confining the whole dialectic art to the single object of disputation, and in omitting many things which respect the general nature of the understanding, and the investigation of truth. Defective as the systenm of Ramus is, lord Bacon (Augm. Sc. l. vi. c. 2.) has passed to severe a censure upon him, and others have concurred in it: for he is unquestionably entitled to great commendation for having, at the period in which he lived and wrote, with so much firmness and perseverance, asserted the natural freedom of the human understanding. The logic of Ramus obtained great authority in the schools of Germany, Great Britain, Holland, and France; and science derived ultimate advantages from the contests which were maintained between the followers of Ramus and those of the Stagyrite. But the fame of Ramus vanished before that of Des Cartes. Brucker's Phil. by Eusfeld, vol. ii.

RAMLA, in Geography, the original Arimathea, a towu of Palestine, distant one-third of a league from the village of Loudd, or the ancient Lydda and Diospolis. This town is almost in as ruinous a state as Loudd itself. Within its boundaries nothing is found but rubbish; yet the agora of Gaza refides here in a fenn, the floors and walls of which are tumbling down. He maintains about 100 homesmen, and as many Barby faders, who are lodged in an old Christian church, the nave of which is used as a stable, and in an ancient kan, which is disputer with them by the focondars. The adjacent country is planted with lofty olive trees, dispersed in quincunxes. Amidst these plantations, which are decaying, are found dry wells, clefts fallen in, and vault vaulted referrers, which prove that, in ancient times, this town must have been upwards of 1½ league in circumference. At present it scarcely contains 200 families. The little land, which is cultivated by a few of them, belongs to the mutfi, and two or three of his relations. There are content themselves with spinning cotton, which is chiefly purchased by two French houses established there. At Ramla there is also a soap manufactuy, the producer of which is almost wholly sent to Egypt. In 1784 the agora built here a wind-mill, which, says Volney, is the only one I have seen in Syria or Egypt, though they are said to have been invented in their countries. The only remarkable antiquity at Ramla is the minaret of a ruined mosque on the road to Yafa. By an Arabic inscription, it appears to have been built by Sai-el-din, sultan of Egypt. From the summit, for it is very lofty, the eye discerns the whole chain of mountains, which begins at Nablous, and skirting the plain, loses itself toward the south. Volney's Travels in Egypt and Syria, vol. ii. Vol. XXIX.
which will sustain floors loaded with the heaviest weights, and of building the largest manufactories in this manner, may adorn all one who has not become an eye-witness of such things. It is a method, which in the above district of France is known by the term pise; but as it is accomplished by the ramming or comparding earth, or earthy substances, in moulds or cafes, the above term has also been applied to it. See Piss, Building in.

RAMMEKENS, in Geography, a sea-port town of Holland, in the isle of Walcheren, formerly one of the chief harbours in Zealand. This town, which was constructed as a fortress in the year 1547, and called “Zeeburg,” was one of the towns pledged to queen Elizabeth by the states general for the succours the lent them against Spain in the year 1585; three miles E. of Flushing.

RAMMEL in Agriculture, a term applied to a substance which forms a part of the subsoil or substrata of particular districts. It is usually covered with a thin weak earth or mould in some places. It is penetrable by the roots of some plants, but notwithstanding that, is very unfriendly to the vegetation of plants in general. It is frequently met with in Cheffure and some other counties. See Soil.

The term signifies a composition of various kinds of clay, white sand, and gravel, which is intimately intermixed with a small portion of oxide of iron. It is for the most part found under a weak brown or grey earth which is rarely more than four or five inches in depth in the above district, lying in strata of from eighteen to thirty inches in thickness, upon a white or red sand or clayey marl, the latter often partaking of its nature for the depth of some feet. Rammels and rammejills are therefore constantly of a barren and unproductive nature.

RAMMELBERG, in Geography, a large and lofty mountain in Westphalia, celebrated for its mines. These mine-workings yield lead, copper, silver, fome gold, borax, lapis calaminarius, zinc, sulphur, jet, vitriol, and yellow ochre. It lies near Goslar.—Alto, a town of Westphalia, in the county of Mansfeld; three miles S.E. of Wippra.

RAMMELLY, in Agriculture, a word used to signify such crops as are tall or rank, as beans, &c.

RAMMER, a well-known implement formed of wood in different ways, according to the purpose for which it is to be used. These implements are very necessary in putting polls into the ground, in inclining land, in order to close the earth firmly about them, as well as for laying down turf or sward, in order to render it smooth and even. See BEETLE.

Ramm of a Gun, the gun-flick; a rod or flail used in charging a gun, to drive home the powder to the breech, as also the shot, and the wad, which keeps the shot from rolling out.

The rammer of a great gun is a cylinder of wood, whose diameter and length are each equal to the diameter of the shot, with a handle fixed to it. See SpurCHE.

RAMNA, in Geography, a mountain of Bofnia; 16 miles N. of Orach.

RAMNAGUR, a town of Hindoostan, in Bahar; 42 miles N.E. of Durbungah.—Alto, a town of Dungal; 10 miles N.E. of Kilheragur.—Allo, a town of Hindooostan, in Oude; 27 mile; N.E. of Lucknow.

RAMONCHAMP, a town of France, in the department of the Voles, and chief place of a canton, in the district of Remignoin. The place contains 2385, and the canton 11,323 inhabitants, on a territory of 245 kilometres, in 6 communes.

RAMONDON, Lewis, in Biography, an English finger, who first appeared on the stage of Drury-lane in 1706. But he sung in Arinoc, and Pyrrhus and Demetrius, when these operas were performed at the Queen’s theatre in the Haymarket. He appears no more as a public singer after this period, but his name occurs as a compositor in a collection of songs called the “Merry Musician,” 1716; and as the editor of the song tunes in the opera of Canilla, contrived and fitted to the harpichord or fipient; in the title of which it is said, “that the lollens being placed on five lines render them proper for a violin and a bafe.” Almost all organ and harpichord music was till this time written and printed on fixed lines.

RAMOO, in Geography, a town of Aracan; 60 miles N.N.W. of Aracan.

RAMOR, LOUGH, a lake of Ireland, in the southern part of the county of Cavan, which contains several islands, on which are held the ruins of some ancient castles. These were formerly adorned with wood, but are now bleak and desolate. The river Blackwater, which issues from it, joins the Boyne at Ravan. Lough Ramor is about 13 miles S. from Cavan.

RAMOS, or LAMOS, a river of Africa, which runs into the Atlantic, 60 miles N.N.W. of cape Formosa. N. lat. 5° 45'.

RAMOS, Dos, an island in the river of the Amazonas, about 70 miles long, and from 10 to 20 broad; 60 miles above Pausis.

RAMOSE LEAF, in Botany. See LEAF.

RAMOTH, in Scripture Geography, a famous city of Palestine, in the mountains of Gilad, and hence called Ramoth-Gilead. This city belonged to the tribe of Gad. It was aligned to the Levites, and was one of the cities of refuge beyond Jordan. According to Ezechias, it was 15 miles E. from Philadelphia; but St. Jerome places it in the vicinity of Jabok, and consequently N. of Philadelphia.

RAMOUH, in Geography, a river of Thibet, which runs into the Deua, N. lat. 50° 20'.

RAMOURY, a town of Hindoostan, in the circuit of Hind; 20 miles E. of Hurdah.

RAMPACH, a town of Hindoostan, in the circuit of Ramundury; 40 miles N. of Rajamundry.

RAMPANT, in Heraldry, is applied to a lion, bear, leopard, or other beast, in posture of climbing, or standing upright upon his hind-legs, and rearing up his fore-feet, Shelley only half of his face, as one eye, and one ear.

The term is French; and signifies, literally, creeping. It is different from soliaent, which denotes a posture left erect, or somewhat flopping forwards, as if making a fall. This posture is to be specified, in blazonning, in all animals, except in the lion and gryphon; it being their natural situation.

RAMPARA, in Geography, a town of Hindoostan, in Concan; 20 miles N. of Gherial.

RAMPART, or RAMPIER, in Fortification, a nasty bank, or elevation of earth about the body of a place, to cover it from the direct fire of the enemy, and of sufficient thickens to defeat the efforts of the cannon for many days; and formed into bastions, curtains, &c.

The word is formed from the Spanish amparo, defence, or covering.

Upon the rampart the soldiers continually keep guard, and pieces of artillery are planted there for the defence of the place. Hence, to shelter the guard from the enemy’s shot, the outside of the rampart is built higher than the inside, i.e., a parapet is raised upon it with a platform. Hence, also, earth not being capable to be raised perpendicularly, like stone, the rampart is built with a talus or slope, both on the inner and outer side.
The rampart is sometimes lined, i.e., fortified with a stone wall within, otherwise it hath a berm.

It is encompassed also with a moat or ditch, out of which the earth that forms the rampart is dug.

The height of the rampart should not exceed three fathoms, this being sufficient to cover the houses from the battery of the cannon; neither ought its thickness to be above ten or twelve, unless more earth be taken out of the ditch than can be otherwise bellowed. See Construction, according to M. Fauban's first Method.

The ramparts of half-moons are the better for being low, that the small fire of the defenders may the better reach the bottom of the ditch; but yet they must be so high as not to be commanded by the covert-way.

Rampart is also used, in Civil Architecture, for the space left void between the wall of a city and the next houses. This is what the Romans call pomerium, in which it was for-hid to build, and where they planted rows of trees, for the people to walk and amuse themselves under.

Ramparts, in Geography, a town of Bengal; 8 miles S.E. of Rangpore.

Ramping, or sodding, denotes the process of building sod or turf walls, or banks.

Rampfersgrube, in Geography, a town of Germany, in the county of Henneberg; six miles W. of Meinningen.

Rampheastes, the Toucan, in Ornithology, a genus of birds of the order Pica, of which the generic character is as follows: Bill very large, light, hollow, convex, ferrate at the edges; each mandible incurvate at the tip; nostrils behind the base of the bill, long, narrow; the tongue is feathered at the edges, the feet moifly climinary.

The birds of this genus first became known to naturalists on the discovery of South America, and to the warmer regions they appear, in general, to be confined. Like the hornbills, they are distinguished by the size of their beaks, which, in some species, is nearly equal to that of the whole body. It is, however, of a very light sub stance, and, in the living bird, it is compreensible between the fingers. Both mandibles are ferrated in an outward direction; the tongue is of a highly singular form, representing the appearance of a very narrow lanceolate feather, being of a somewhat horny or cartilaginous nature, and divided on each side into innumer able short and clofe-fet fibres; in consequence of which structure it was described by some early writers on natural history as a real feather, supplying the place of a tongue. The orbits of the eyes are generally bare. The toucans are suppos ed to feed on fruits, but in a state of captivity they will eat animal food. They deposit their eggs, which are usually two in number, in the hollows of trees, on the surface of the decayed wood. These birds have been as yet met with only in South America, and there merely between the tropics, being totally incapable of su f taining the cold. They are easily tamed and familiarized, and several species have been brought to England, where fruits, fish, and flesh have been promiscuously devoured by them with considerable voracity. Whatever was received by the bill was thrown into the air, and on its return caught, and, without the slightest mastication, instantly devoured. There are fourteen species enumerated by Gmelin, though Mr. Latham mentions only fifteen.

Species.

Viridis; Green Toucan. Green, with a yellow belly, and red rump. This species is found in Cayenne, and is about fourteen inches long. The upper mandible is yellow, with red sides, and a black line in the middle; the lower one is black, the base and round the nostrils are red; the teeth in both are white; the irides and naked orbits are yellow; the legs are of a lead colour; the claws are black; the tail is wedged, beneath inclining to ash; head, chin, and throat, in the male black, in the female bay, terminated by a black narrow transverse band.

Edentulus; Toothless Toucan. In this the bill is not ferrate at the edges. It inhabits Cayenne, and is twelve inches long. The upper part of the body is green, but beneath it is more of a yellowish colour; the head and neck are chestnut; the rump is red; the upper mandible is brown, the lower black; the thighs green, and it is thought to be a variety of the viridis.

Pavonicus; Pavonine Toucan. The general colour of this is green; but the feathers are sprinkled with red spots. It is also known by a mixture of red and changeable or peacock-coloured feathers intermixed. The bill is variegated yellow and black; the legs and claws are black.

Piperivoros; Pipering Toucan: Green; the fore parts are black; the vent and thighs red. This species has been described by Edwards under the name of the green toucan. Its length is about seventeen inches, and its general colour is of a dull green; the head, neck, and breast, are of a deep black; behind each ear is a somewhat lengthened orange-coloured spot, and immediately behind the lower part of the neck is an orange-coloured bar or collar; the belly is pale, and yellowish-green; the thighs are purple; the vent is red, and the tail, which is cuneate, slightly tipped with dull red; the bill is about three inches long, and of a black colour, but towards the base it is varied with red, white, and orange-yellow. In the female the head, neck, and breast, are brown instead of black, and the lower part of the belly is grey. It is a native of Cayenne, and fed to feed on the pepper of the country. The female of this species has been known to vary in having the bill of a horn colour, with a black bar near the end, and two others near the edge; the ridge also being black, and the yellow crescent at the neck is wanting.

Aracari. This species is green, but the abdominal band, vent, and rump, are red; the belly and breast are yellow. It is a native of Brazil, Surinam, and Cayenne, and is full sixteen inches long. The upper mandible is black on the back and tip, but the sides are whitish. The base is three-lobed at the nostrils, with a white arch at the root, lower black; the head, the wings, and tail, are black; the breast and body are yellow and scarlet, with a black roundish spot in the middle of the breast, and a similar transverse one on the beginning of the belly; the thighs are tawny.

Torratus; Collared Toucan. This bird is black above, and beneath it is whitish; the belly is green, the hind part is red, and the collar red. It inhabits the coasts of New Spain, is about eighteen inches long, and feeds on fish. The upper mandible is blackish, and the lower black; the irides are of a reddish-yellow; the head and neck are black; the lower tail-coverts are red; the thighs purple; the legs are of a greenishash colour; the claws are black.

Piicivorus; Brazil Toucan. This is blackish, but the abdominal band and vent are red; the rump is white. It inhabits South America, and is twenty-one inches long. The bill is yellow, with a scarlet spot on the tip; the lower mandible is blue; the cap, back, wings, tail, belly, and thighs, are black; the temples, chin, breast, and rump, are white.

Erthroryncchos; Red-throated Toucan. Blackish; cheeks, chin, and throat, white; upper tail-coverts sulphur, but the lower and crescent on the breast are red. This is found
found in various parts of South America. The beak and back of the bill are yellow; tip of the upper mandible, and hollow of the lower, red; the nostrils are edged with black; the orbits are blueish; the legs are plumbeous, and the claws are black.

**Tucanus;** Yellow-breasted Toucan. This is also blackish; the abdominal band, vent, and rump, yellow. It measures about nineteen inches in length, and has been described by Mr. Edwards from a living specimen brought into England. According to this gentleman, the bill of this species is large in proportion to the size of the bird; it is compressed sideways, having a sharp ridge along its upper part, and toothed on its edges; the upper mandible is green, with a long triangular spot of orange colour on each side, and the ridge on the upper part yellow; the lower mandible is blue, with a shade of green in the middle; the point is red; it has about five transverse faint dully bars, which cross the junctions of the two mandibles; the nostrils are invisible in the black line that surrounds the bill; the iris of the eye is of a fair green colour; round the eye is a broad space of naked skin, of a violet colour; the skin beneath the feathers is of a violet color, below which is a bar of scarlet feathers, which parts the yellow on the breast from the back on the belly; the coverts-feathers of the tail are white above, and those beneath are of a fine red; the crown of the head, upper part of the neck, the back, wings, belly, and tail, wholly black, though on the upper side of the wings and tail it has a changeable gloss of blueish-purple; the legs and feet are all of a blue or violet colour. The specimen from which this description was made, was brought from Jamaica, but the bird is a native of the hotter parts of South America.

**Picaetus;** Preacher Toucan. Blackish; breast yellow, vent and tips of the tail-feathers red, rump black. It inhabits Guinea and Brazil, and is more than twenty inches long. The bill is yellowish-green, tips with reddish; the belly is red; the tail is dotted with red at the tip. This bird is said to have a frequent habit of moving its head from side to side, while uttering its notes; hence it has obtained the name of preacher.

**Dicolorus;** Yellow-throated Toucan. Blackish; breast, belly, vent, and rump, red; the chin is yellow. It inhabits Cayenne, and is fourteen inches long. The bill is olive, with a black base; the mandibles are edged with red; the cheeks are of a sulphur colour; the throat is orange, but edged with sulphur.

**Toco;** White-throated Toucan. Blackish; chin, throat, and rump, white; orbits, circle on the breast, and vent, red. It inhabits Cayenne, and is about nine or ten inches long. The bill is of a reddish-yellow, the base is black; the upper mandible is black at the tip.

**Indicus;** Indian Toucan. The throat, quill-feathers, and tail, black; the cheeks and breast are white; belly and thighs are yellow; the crown is of a reddish-orange; rump crimson. It is found in divers parts of India. The bill is hardly serrate, and not so large as in the others.

**Luteus;** Yellow Toucan. This is of a yellowish-white; the neck is marked with two black lateral stripes; the tail and wings are variegated with black and white; the lesser wing-coverts are yellow. It inhabits New Spain, and is about the size of a pigeon. The bill is black; the irides are yellow; the legs are brown; the claws are yellowish.

**Caruleus;** Blue Toucan. Blue mixed with cinereous. It inhabits the coasts of New Spain. The bill is longer than the body; the eyes are black and the irides are tawny.

**Durius;** This is the blue-throated toucan of Mr. Latham, described from a catalogue of the museum of baron Fangere of Montpellier, where it is announced as an undescribed species.

**Albus;** White Toucan. This is entirely white.

**Ramps, in fortification, are gentle slopes made for the cannon to be drawn up and down by; and also for the easy communication of the troops posted in a battery that is raised above the level of the ground on which it is built. The rife of these slopes is about two inches, on twelve of base, or the length of the ramp's base is six times the height, and this is general for the draught of carriages; but footways need not be of so gentle a slope, as a rife in one foot in three may answer the purpose; or, instead of ramps, stairs may be, and commonly are, used for the passage of the foot. The breadth of a carriage ramp is usually about nine or ten feet, that breadth being sufficient both for the carriage and footway; but those for foot-passage only need not be above three or four feet wide. Ramps may either rife on the side of an elevated work, or against a slant angle of that work, or on each side of an entering angle.**

**Ramsay, Allan, in Biography, a poet of considerable celebrity, who wrote in the Scottish dialect, was born in the year 1636, in the parish of Crawford, Lanarkshire. He received no other education than that of the parish school, and was apprenticed to a barber in Edinburgh. It has not been ascertained when he first began to make verses; but about the year 1715, several of his poems had been published. Soon after this he laid aside the trade to which he had been brought up, and adopted the more congenial one of a bookseller. In 1721 his detached poems were published, in a quarto volume. In 1724 he began to publish his collection of songs, entitled "The Tea-table Miscellaneous," which at length extended to four volumes. This work was followed by one, entitled "The Evergreen," being a collection of songs written by the ingenious before the year 1600. These publications were well received; but his fame was greatly extended by his **"Gente**
"Gentle Shepherd," which was afterwards enlarged from two pastoral poems, in the form of a regular drama. He now held a correspondence with several poets and other ingenious persons of the time, and his shop in Edinburgh was the resort of the men of letters who then flourished in the capital of Scotland. He is supposed to have opened the first circulating library in that city, and in 1726 he built a play-house, which was the first ever known at Edinburgh; but the act prohibiting the exhibition of plays in unlicensed buildings, caused it to be shut up. Ramfay, towards the middle of his life, withdrew from the field of authorship, and attended to the much more profitable buffets of selling, rather than writing of books. He died in 1758, at the age of 71. The poems of Allan Ramfay, says an eminent critic, "display none of the fire of the genius so conspicuous in those of Burns, but have occasionally an agreeable pastoral simplicity, and are often marked with a vein of humour, natural, though coarse. The Gentle Shepherd is, perhaps, one of the best pastoral with respect to the pictures of real life, which are drawn with great propriety, and generally present pleasing images."

Ramsay, Allan, son of the preceding, was born at Edinburgh about 1709, and having devoted himself to painting, went at an early period of his life to study in Italy, and there received instructions from Solimene and Imperiale.

After his return, he praetified in Edinburgh for some time, but afterwards removed to London, and by the influence of his countryman, the earl of Bute, was introduced into the vortex of the court, painted the prince of Wales, and on the death of Shahkot in 1767, was appointed principal painter to the crown; although Reynolds was then in possession of the highest reputation.

Ramfay never ventured to attempt the higher walks of the art, but confined himself solely to portraits, which he painted agreeably. Not possessed of brilliancy of genius sufficient to attempt strong character, with striking effects in his pictures, he contented himself with that portion of art which meets the expectations of common observers; never offending with affectation or neglect, he finished his pictures with care and neatness, and retained his friends and reputation till he ceased to praetifie. He was so far attached to his art, that he visited Italy four times; to what purpose does not appear, unless it was to derive benefit from the portraits of Pompeo Battoni; for no traces of higher character are observable in his productions. Yet he was a man of found sense and strong understanding; possessed of literary acquisitions, and devoted to study. Though he understood the Latin, French, and Italian languages, he was not satisfied till he added a knowledge of the Greek, acquired when he was advanced in life. Thus endowed, he was emulous of literary fame, and published, under the title of "The Inveighator," Essays on Ridicule, as the tale of truth, on the Naturalization of Foreigners, on Taste, &c.; and, as occasion prompted, the town was favoured by him with some fugitive pieces on the politics of the day. He was always held to be highly estimable as a man, and enjoyed his fame and good fortune to about the advanced age of 75.

Ramsay, Andrew Michael, called the chevalier Ramfay, was born at Ayr, in Scotland. He received a good education at Edinburgh, where he distinguished himself so much, that he was chosen to attend the son of the earl of Weemys at St. Andrew's. After this he went to Leyden, with the view to farther improvement, where he became acquainted with Poirot, one of the leaders of the Quietists, some of whose doctrines he imbibed. He next went on a visit to the celebrated Fenelon, archbishop of Cambray, who converted him to the Roman Catholic religion, and Ramfay ever after this considered himself as the disciple of that excellent prelate. Upon his works he formed his literary taste, and he even adopted France for his country, and made use of its language in his writings. Here he obtained some polls of honour and emolument, and was made knight of the order of St. Lazarus, whence he had the title of chevalier. His reputation caused him to be invited to Rome by the Pretender, in order that he might undertake the care and education of his children. This he accepted; but having found that little court so divided by factions, he quickly resigned his office, and returned to Paris. In the next year, 1755, he revisited his native country, and resided some years with the duke of Argyle, employing himself in the composition of several works. After his return to France, he entered into the service of the prince of Turenne, duke of Bouillon. He died in 1753, at St. Germain-en-Laye, the retreat of the exiled Stuart family, at the age of 77. His principal writings were, "L'Histoire de la Vie et les Ouvrages de M. de Fenelon," "Essai pour le Gouvernement Civil," "Difcour sur le Poeme Epic," "Le Psychometre," being remarks on lord Shaftesbury's Characteristic; "L'Histoire du Marchal de Turenne," and "Les Voyages de Cyrus." The last is that which is by much the best known, and it has been frequently printed in the French and English languages. Voltaire has stylized it a feeble imitation of Telemachus; it is, however, written with elegance, but is tedious. Another of the chevalier's works was "A Differtation on Free-Masonry," of which he was grand chancellors of France. In this he traces the origin of the institution to Palestine, in the time of the Crusades; and having found a great declension of the mythical ceremonies formerly practised, he strongly urged their renewal, and proposed a general assembly of the brotherhood of all nations to be held at Paris. Biog. Brit.

Ramsay, in Geography. See Ramsey.

Ramsay Point, a cape on the S.E. coast of the island of Lewis. N. lat. 57° 44'. W. long. 6° 36'.

Ramsbury, a village and parish in the hundred of Rambury, and county of Wilts, England, is situated about five miles to the eastward of the town of Marlborough, and 70 miles by south from London. In the time of the Saxons it was a place of so much importance, as to be constituted the seat of the king, when Wiltshire was made a distinct bishopric by Plegmund, archbishop of Canterbury, in the year 909. Rambury church was then the cathedral church of the diocese, and continued to be so till bishop Herman prevailed upon king William the Conqueror to unite the bishoprics of Wiltshire and Sherborne, and fixed his episcopal seat at Old Sarum. The church, an ancient building, is divided into a nave, two aisles, and a chancel, with a massive square tower at its western extremity. In the chancel is a long stone, which tradition affirms to be the grave-stone of a giant; also an old altar tomb of Purbeck marble, without any inscription, and several monuments commemorative of the Joneys of Rambury manor, or park. This seat is now the property of Sir Francis Burdett, bart. in right of his mother, second daughter of the late William Jones, esq. The house was designed in the Grecian style, by John Webb, nephew to Inigo Jones. The icicles are extensive and well wooded, and are intersected by a branch of the river Kemar, which spreads itself out in this form of a lake, from the sides of which the grounds rise in easy, sloping lawns.

Littlecot park, the seat of major-general Edward Leybourne
bourne Popham, is situated partly in the parish of Ram- 
bury, and partly in that of Chilton-Foliot. The house is 
a large ancient structure, built by one of the Darells, the 
former possessors of this domain, about the time when 
feudal warfare ceased, and defence was no longer an object 
in a country manion. Notwithstanding many late altera-
tions, the interior still preserves many of its original features. 
The great hall is very spacious, floored with stones, and 
lighted by large and very lofty windows. In it stands a 
large oaken table, at which the valets of the domain were 
wont to feast at the expences of their lord. The remainder of 
the furniture is in a suitable style, particularly an arm-chair, 
which is said to have been used by sir John Popham, chief 
justice of the court of king's bench in the reigns of queen 
Elizabeth and king James I., who purchased the house and 
manor from the last of the Darells. There is also a curious 
instrument for the punishment and confinement of servants; 
by fastening their thumbs between two boards. The walls 
of the hall are decorated by numerous guns, carabines, pifols, 
doublets, &c.: and here are also two very fine candelabras, 
designed and executed by Mr. George Bullock of London, 
in an admirable style, as adapted to the age and character 
of the mansion. One of the bed-rooms is said to have been the 
scene of a singular and mysterious murder, the incidents 
attending which are recorded in a note to Scott's poem of 
Rokeby. In the gallery, which is about 110 feet in length, 
are portraits of judge Popham and Nell Gwyn; also a 
curious piece of needle-work, representing a large Roman 
tessellated pavement, which was discovered in the adjoining 
park in 1728, by Mr. George (flewared to Edward Popham, 
efq.), who made a coloured drawing of it, and communici-
cated the fame to the Society of Antiquaries. This pave-
ment consisted of two divisions, which appear to have 
formed the floor of a temple. The interior division was 
ornamented with the figure of Apollo playing on a harp; and 
in four surrounding compartments were four female figures 
riding on different animals, and designed to represent the 
Hera, or Seacons. Exterior to the circle inclining them 
were three other compartments, each displaying a face of 
the sun. From these circumstances the temple is supposed 
to have been dedicated to Apollo; but some enclaves on 
it exterior division referring to Ceres and Neptune, it may, 
perhaps, be more properly esteemed a port of pantheon. 
Another smaller Roman pavement, and a curious cup or 
patera of bracis, were likewise discovered by Mr. George 
on Rudge-farm, adjoining the northern boundary of Little-
cot park. The cup was adorned with foliage, and was 
inscribed with the names of five Roman flations. It was 
conjectured by Gale to have been a libation cup used at 
an annual feast instituted by the inhabitants of the town. 
Pickfied, in this vicinity, is a government depot for the 
interior, established in 1803. It includes about forty acres 
of ground, on which are erected three magazines for powder, 
haracks for a detachment of the military, and various 
neceffary houses and offices. Beauties of England and 
Wales, vol. xv. by John Britton, F.S.A.

RAMSDAL. See Remsdal.

RAMSDEN, Jesse, in Biography, an eminent English 
mathematical and astronomical instrument-maker, the fon of 
an inn-keeper at Salterhebble, near Halifax, in Yorkshire, 
where he was born in the year 1735. At nine years of age 
he was admitted into the Halifax free-school, where he acquired, 
during three years, the elements of classical learning; after 
which he was removed to the care of an uncle at Craven, 
by whom he was sent to a clergyman of the name of Hall, 
who had acquired much reputation by teaching at his school 
the mathematical sciences. Under this gentleman's instruc-
tions, young Ramden became a proficient in geometry and 

algebra, and was advancing rapidly in thefe and other col-
ateral branches of study when his father sent for him home, 
to apprentice him out with a clothier at Halifax. At the 
age of twenty he went to London, where he became clerk 
in a wholecaf cloth warehouse. This situation he retained 
about two years and a half, when his inclination for the 
sciences revived so strongly, that he resolved to qualify him- 
self for some business which should prove fuitable to the 
bent of his mind. With this view he bound himself appren-
tice for four years to Mr. Burton in the Strand, who 
was esteemed one of the best workmen of his time in 
making thermometers and barometers, and in engraving and 
dividing mathematical instruments. After the expiration of 
his apprenticeship, he worked as journeyman with a perfon 
of the name of Cole, with whom he afterwards advanced 
himself as partner. This connection did not last long, 
when Mr. Ramden opened a workshop on his own ac-
count, in which he soon recommended himself to the em-
ployment of the principal mathematical instrument-makers 
in London. In the course of his business his repeated exa-
nimation of the instruments which were sent him to be en-
graved or divided, led him to discover their defects, and his 
genius suggested to him the means of removing them, or of 
contructing better instruments. In order to put his plan 
into execution, he made himself master of the prac-
tical operations of the trade, and formed the design of 
examining every astronomical instrument in use, with the 
view of correcting those which, being founded on good 
principles, were faulty only in the construction, and of 
proscribing those which were defective in both these 
respect. About this time, by his marriage with Mifs Dol-
 loud, he became possessed of a part of Mr. Dollond's paten 
for achromatic telescopes. In the year 1766, Mr. Ramden 
opened a shop in the Haymarket, where he continued till 
1774, when he removed to Piccadilly, where he remained 
till the time of his death. Before his settlement in the 
Haymarket, he had improved the sextant, and he had in-
vented his celebrated dividing machine. (See the art. En-
gine.) Having spent ten years in bringing this machine 
to perfection, he obtained from the Board of Longitude 
a premium of 1000l. Mr. Ramden constructed an instru-
ment for dividing straight lines, which has been decribed 
in a former volume of the New Cyclopaedia, and while he 
was employed on his dividing-machine he made great im-
provements in several other instruments. The THEODOLITE 
(see the article), before his time, confined merely of a 
telescope, turning on a circle, divided at every three minutes, 
by means of a Vernier, which fee; but in the hands of 
Mr. Ramden it became a new and perfect instrumet, 
serving for measuring heights and diliances, as well as taking 
angles. The largest and most perfect theodolite ever con-
structed was made by him for general Roy, for the purpose of 
measuring the series of triangles in England. Though 
this instrument is only of eighteen inches radius, its accuracy 
is so great as not to admit of an error of a single second. 
With this instrument general Roy meafured the angle be-
tween the polar star and the fides of his triangles, in order 
to have the exact difference between the observations of 
Paris and Greenwich, which he found to be 9'20". Mr. 
Ramden was a great improver of the barometer for 
measuring the height of mountains, which he could ob-
tain to a degree of accuracy that was very surprifing, 
and he caufed to be engraved a table to accompany his 
barometers, which, without the trouble of calculation, 
gives the heights of places, according to the heights of 
the mercury, and even at different temperatures. He also 
pointed
pointed out a new method and apparatus adapted to the conveyance and support of the portable barometer. Mr. Ramsden made improvements on the electrical machine; and on manometers for measuring the density of the air; he invented an instrument for measuring inaccessible distances; he affaying balances which turn with less than a tenth-thousandth part of the weight used; levels and a variety of other instruments. The pyrometer also exercised his talents, and on this occasion, as on all others, Mr. Ramsden shewed a sort of natural and almost intuitive faculty in discovering the essential faults of an instrument, and in inventing the most simple and exact methods of correcting them. With respect to optics, he discovered a method of correcting, in a new and perfect manner, the aberration of sphericity and refrangibility in compound eye-glasses applied to all astronomical instruments. Opticians had imagined that the purpose might be accomplished by making the image of the objects fall between the two eye-glasses, which was attended with this great inconvenience, that the eye-glasses could not be touched without deranging the line of collimation, and the value of the parts of the micrometer. To remedy this inconvenience, he set out from a simple experiment, viz. that the edges of an image observed through a prinl are less coloured, according as the image is nearer the prinl. This led him to attempt placing the two eye-glasses between the image of the object-glasses and the eye, without failing to correct the two aberrations; which he did by changing the radii of the curves, and placing the glasses in a manner very different from that commonly employed. In the Philo-

ical Transactions for the year 1779, Mr. Ramsden has described a new reflecting object-glass micrometer; to the paper on this subject we refer our readers, and also to the article Mierometer in this Dictionary. With this micro- meter the diameters of the planets may be measured; it may be adapted to all kinds of achromatic telescopes; it may be brought near to, or removed from, the object-glasses at pleasure, to render vision distinct; and it may be removed from the telescope, if the observer wish to use the latter without a micrometer. The high degree of merit to which Mr. Ramsden's many and important inventions were intituled, led his friends to propose him as a member of the Royal Society, and he was elected in the year 1786.

The Equatorial or Transj instrument (see the articles) received great improvements in the hands of Mr. Ramsden, who rejected the endless screw, which by prejising on the centre destroyed its precision; he placed the centre of gravity on the centre of the base, and caused all the movements to take place in every direction; he pointed out the means of rectifying the instrument in all its parts, and he applied to it a very ingenious small machine, for measuring or correcting the effect of refraction. The greatest equatorial instrument ever attempted, is that which he constructed for Sir George Shuckburgh, on which he employed several years, and of which we have given a description and figure. Mr. Ramsden's meridian telescopes which he made for Blenheim, Manhaim, Dublin, Paris, and Gotha, are also remarkable for the excellence of their object-glasses. With that of Dublin, Mr. Uther observed stars of the fourth magnitude in the open day, and those of the third very near their conjunction with the sun. These telescopes are eight feet in length. There is a five-feet one at the observatory at Palermo. Mr. Ramsden made great improvements in the mural quadrant, of which a full account will be found in the article Circle, to which we refer our readers for much valuable information on the subject of astronomical instruments. Having in various parts of our work entered into the nature of Mr. Ramsden's improvements and inventions, it is unnec- essary to repeat here what has already been fully explained. In the field in which the inventive genius and superior talents of Mr. Ramsden were exercised, was, as we have been, very extensive. In order that every part of his instrument might be fabricated under his own inspection, he collected in his workshops men of every branch of trade necessary for their construction. So important did he consider the principle of division of labour, that he always confined the same workmen to the fame branch, and by that means arrived at the greatest correctness and nicety in executing it. Notwithstanding the great perfection of his instruments, which ought to have fac- curred to Mr. Ramsden a large fortune, he sold them cheaper than any other artist in London, sometimes even one-third below the usual price. Such was the demand for them, from almost all parts of the world, that though he employed sixty men, he was unable to execute all the orders which he received. His great attention to business injured his health, and hastened his death. He died at Brighton, where he had been for the benefit of the sea-air, November 5, 1800, in the sixty-sixth year of his age. He had been elected a member of the Imperial Academy of Sciences at Petersburg in 1794, and in the following year he was presented with the gold medal, adjudged by the Royal Society to persons dis- tinguished for their scientific talents.

Mr. Ramsden was by nature endowed with uncommonly strong reasoning powers, and a most accurate and retentive memory, but, at the same time, with such a quickness of penetration, that he could, as it were, with a single glance, view in every light the subject on which he thought, and adopt the most advantageous mode of considering it. He possessed, in an exquisite degree, that quality of mind which is emphatically styled elegance, which in the abstract sciences leads to clearness, simplicity, and precision, as in the fine arts and literature, it gives the last polish to genus, and is more generally known by the appellation of taste. In his habits he was temperate to abstinence, satisfied with small quantities of food, and a small portion of sleep. Unacquainted with dilipation or amusements, and giving but little time even to the society of his friends, the whole of those hours which he could spare from the duties of his profes- sion, he devoted either to further improvements in his in- struments, or to the perusal of books of science, particularly those mathematical works of the sublime writers which had any connection with the subject of his own pursuits. Mr. Ramsden's only relaxation from almost constant and severe studies, was the occasional perusal of the best authors, both in prose and verse; and when it is recollected that at an advanced age he made himself to completely master of the French language, as to read with peculiar pleasure the works of Bocage and Moliere, we cannot believe that he mis- spent even his hours of amusement. Short and temperate as were his repasts, a book or a pen was the constant com- pany of his meals; and when illneses broke his sleep, a lamp and a book were ever in readiness to beguile the fenes of pain, and make bodily sickness minister to the progress of his mind. He was well skilled in the abstruser parts of mathematics, and conversant with the best writers on the sciences; and such was his manual dexterity, that there was not one tool in any of the numerous branches of his profes- sion which he could not use with a degree of perfection equal to that of the very best workmen in that particular branch, and he could have begun and finished every single part of his most complicated instruments. For this article we are chiefly indebted to a very elaborate and excellent ori- ginal memoir in the 8th vol. of the Gen. Biog.
decoration, appear ranges of small semicircular arches springing from plain octagon pillars; the capitals of the piers which support it add displaying some curious sculpture. Among the sepulchral memorials here, are several in memory of the Sparkings of Eltington, and the Mansions of Mantle-court, an ancient mansion, situated about two miles to the north-west of St. Lawrence, now converted into a farm-house. Minlock, another village in this vicinity, derives its name from a church or nunnery founded here in 626, by Domneva, wife to Merwald, son of Penda, king of Mercia. In the early part of life she had been left, with her fitter Ermergitha, and her brothers Ethelred and Ethelbright, under the guardianship of her uncle Egbert, king of Kent, who murdered the princes, and in expiation of the crime offered to give to Domneva whatever she should ask. The lady demanded as much land as a tame deer would run over at one course, to endow a monastery, which was accordingly granted to her. When her buildings were raised, the place therein 70 nuns, and, taking the veil herself, became their first abbess. She was succeeded by her daughter St. Mildred, from whom the abbey afterwards was denominated St. Mildred's Abbey. This establishment was frequently plundered by the Danes during the eighth and ninth centuries, and at length was yet fire to, and totally destroyed, together with the nuns, the clergy, and many of the people who had fled hither for sanctuary. The possessions of this abbey were subsequently granted to the monks of the monastery of St. Augustine, in Canterbury; by king Canute, and by them the body of St. Mildred was removed to their own abbey. The parish church of Minlock, which occupies the site of the ancient nunnery, appears to have been originally founded about the time of the conquest, but it has undergone many alterations, and consequently exhibits various styles of architecture. The nave, which is the oldest portion of it, is divided from the aisles by semi-circular arches springing from short massive columns. The chancel is vaulted with stone, as is likewise part of the transept. Beauties of England and Wales, vol. viii. by E. W. Brayley, History of Kent, by Edward Hasted, etc., 8vo. edit. vol. x. Lewis's History of the Isle of Thanet, 4to.

RAMSHAGUR, a town of Bengal; 5 miles S. of Dinagonpur.

RAMSHYDA, a town of Sweden, in the province of Norcia; 28 miles N. of Orebro.

RAMSIN, a town of Saxony; 3 miles W. of Bitterfeld.

RAMSONS, in Botany, a name given to the broad-leaved wild allium. See Allium.

RAMSTADT, in Geography, a town of Heilie-Darmstadt; 3 miles S.E. of Darmstadt.

RAMTCHIEU, a lake of Tibet, formed by three separate rivulets, and surrounded with an incrustation, of a white colour and falthy taste. This substance is collected and employed for cleaning and washing woollen and cotton cloths, as a substitute for soap, to which the inhabitants of the adjacent country are utter strangers. Near this lake is a large monastery, called Lulchea Goomba, seated amidst rocks, which protrude their heads into the lake, and are bordered with a white foam, produced by its agitated waves. The banks of this lake are perforated with innumerable burrows of a small animal, to which they give the name of rat, larger than a mink rat, of a cinnarose grey, without a tail, conceiv'd by Mr. Turner to have been the daman of Herod and Egypt, or the Schapman of the Hebrews. The lake is also frequented by great abundance of water-fowl, wild geese, ducks, teal, and storks, which, on the approach of winter, take their flight to milder regions. Predigions numbers of fowrasses, the largest species of the crane kind, are here seen at certain feasons of the year, so that any quantity of eggs may be collected. The lake gradually narrows, and from its northern edge ends off 2 small brooks & at the other extremity it discharges itself into a much larger lake. This lake, it is said, is held in high respect by the inhabitants of Boottal, whose superstition leads them to consider the increase or decrease of its waters as portentous of good or evil to their nation. They fancy it to be a favourite haunt of their chief deities. Turner's Thibet, p. 212. &c.

RAMTEAK, or Ramtegii, a town of Hindostan, in the cirec of Goondwana, held sacred by the Hindoos, who pretend that Ram collected his army here, prior to his expedition against Rawun at Lanks, or Ceylon. The Hindoos believe all the Europeans to have descended from Rawun, and Ceylon to be an immense mountain of gold invisible to them. Near the town is a temple, in which they offer up their sacrifices and devotions; 15 miles N.E. of Nagpurn. N. lat. 21° 29'. E. long. 79° 57'.

RAMTRUT, in Mythology, the name of a deity worshipped by the Karazins, a people of Hindoostan, where he has a celebrated temple, at Onor. The characters under which he is represented more refeible thole of a monkey than of a man.

RAMULOSE LEAF, in Botany. See Leaf.

RAMUNDA, or Romla Boda, in Geography, a town of Sweden, in Norcia.

RAMURAH. See Ramgar.

RAMUS, Peter, in Biography. See Ramists.

Ramus, in Anatomy. This word, signifying branch; and the term ramification, are used in describing the arteries, veins, and nerves, the divisions and subdivisions of which bear some analogy to the branching of a tree. In the same way we speak of trunks of arteries, &c. and describe them as branching out.

Ramus, in the Anatomy of Plants, a name given to the first or lateral branches, which go off from the petiolum, or middle rib of a leaf. The subdivisions of these are called furculi; and the final divisions of these into the most minute of all, are by some called capillaments; but in general, both these kinds are comprehended under the name of furcules.

RAMUSIO, or Ranzusio, Giambatista, in Biography, an early collector of voyages and travels, the son of Paolo, an eminent lawyer, defended from a learned and distinguished family of Venetian citizens, was born at Venice in 1485. He was in early life deputed by the State upon public business to Switzerland, Rome, and France; and in the latter country he so much ingratiated himself with Lewis XII., that he was by him caufed to travel through almost the whole of his kingdom. As a reward for his services, he was made secretary of the council of ten at Venice, which post he at length resigned; and returning to Padua, employed himself in compiling his great work, "Raccolta delle Navigazioni e de Viaggi," which was published at different periods between the years 1554 and 1559, in three volumes folio. He had prepared a fourth volume, which was burnt at the printer's. Ramusio died at Padua in 1557; of course, a part of his work was given to the world after his decease. Ramusio was author of a treatise "De Nili Incremento." He was a man of great learning, and was extremely converfent in history, geography, and the ancient languages; he had some knowledge in astronony, and held a correspondence with many learned men and well informed persons, both in Italy and Spain. It was by their allience, and at the desire of Fracelloro, that he composed the
the work already mentioned. This work was a collection of all the voyages and travels that had hitherto been published; in which he gave translations of those in foreign languages; and he prefixed dissertations, in which he diligently examined the pretensions of different authors, comparing them with one another.

RAN, in our Old Writers, is used for open and public robbery, so manifest that it cannot be denied. "Ran dicitur aperta rapina que negari non potest." Lamb. 125. Leg. Canut. cap. 58. Hence it is to this day vulgarly said of one who takes the goods of another injuriously and violently, that he has taken or stalked all he could rap and ran.

RAN, twenty cords of twine, wound on a reel; and every cord fo parted by a knot, as to be easily separated.

RANA, in Geography, a town of Austria; 12 miles S. of Aigen.—Also, a town of Austria; 13 miles S.S.W. of Zwettl.

Rana, or Oranai, one of the Sandwich islands, in the North Pacific ocean, situated about three leagues from Mowee and Morotai, and lying to the S.W. of the passage between those islands. The country to the south is high and craggy; but the other parts of the island had a better aspect, and appeared to be well inhabited. It produces very few plantains, and bread-fruit trees; but abound in roots, such as yams, sweet potatoes, and taroow. The number of inhabitants is estimated at 20,400. Its S. point is in lat. 20° 45'. E. long. 203° 8'. Cook's Third Voyage, vol. iii.

Rana, in Surgery. See Ranula.

Rana, in Zoology, the frog, a genus of the class Amphibia, of the division Reptiles, of which the generic character is: Body four-footed, naked; it generally has no tail, the hind legs are longer than the fore. This genus differs from the Lacerta (see the art. Lizard), in having a shorter body, broader, thicker head, and in general no tail. The animals of it feed on insects; they are all grown about the fourth year, and seldom live beyond the twelfth. Their fore-feet are mostly clefled, having four toes: their hind-feet are palmate and five-toed; they are extremely malicious, flocking to the female for days and weeks: the tadpole is excluded from the egg without feet, but with a tail resembling a fish's, which drops off as the legs are protruded; in this state they have likewise a fort of gills and lungs, and many have a small tube on the lower lip, by which they can affix themselves to other bodies; near the left eye is a vessel, from which they discharge water; in breeding time, the fore-thumb of the male is warty: toads, as we all know, are filthy in their aspect, and live in damp, obfure, dark places, and crawl out only by night: their eggs are in a long chain: frogs are more active, and more about by day; these lay their eggs in a confused mass.

Dr. Shaw, in his entertaining and instructive Zoology, says this genus may be divided into three sections, viz. 1. Frogs, commonly called Rana, with light active bodies, and which leap when disturbed. 2. Slender-limbed frogs, Hylæ, Calanites, or Rana arborea, viz. such as have light bodies, very slender limbs, and toes terminating in flat, circularly expanded tips, enabling the animal to adhere at pleasure to the surface even of the smoothest bodies. Several of this division actually reside on trees, adhering by their toes to the lower surfaces of the leaves and branches. 3. Toads, Bufò, or such as have heavy bodies, short thick limbs, and which rather crawl than leap when disturbed.

Gmelin has given a different arrangement, which, according to our usual custom, we shall follow in this article. He divides the genus into three sections, viz. A, those with warty and puffed up bodies; and short legs: these are Rana. B, those with bodies rather oblong, smooth and with longer legs: these are Rana and Arvium, properly so called. And C, whose hind feet are very long; and whose claws are lenticulate. Dr. Shaw enumerates more than forty species, but Gmelin describes only thirty-six.

Section A.—Body warty, puffed up: shorter legs.

Species.

Pipa; Surinam Toad. The toes of the fore-feet of this species are unarmed, four-footd; those of the hind-feet are clawed and palmate.

This hideous and deformed animal inhabits the waters of Guiana, and is actually eaten by the natives. The male, after the exclusion of the eggs, collects the maws together, and finears it over the back of the females with its paws, where they are received into small cells, impregnated by the males and closed up; after some time the perfect young are excluded from these hollow tubercules on the back of the female.

The size of the Pipa considerably exceeds that of the common toad; the head is flat, broad, and very short; the heak is spatula-shaped; the eyes very small and remote; neck very short, wrinkled; the body is orbicular, flat, with a hard cartilaginous skin; the fore toes are round, and the hind ones very long, connected by an undivided membrane. This species was first made known to the Europeans at the latter end of the 17th century.

Muscisca; Musical Toad. The specific character of this is, that it has gibbous shoulders that are dotted; the body is variegated with purplie and brown; the fore-feet are cleft, and the hind-feet are subpalmate and five-toed, with five claws. It inhabits the fresh waters of Surinam; it is larger than the common toad: in the evening, and during the whole night, it keeps up a continual musical kind of croaking; hence it takes its name.

*Bufo; Common Toad. Body luriid and brown: of this animal there are three varieties, as follows: the first has its back of an olive colour; and an unequal yellowish-red band down the side: the body of the second is marked with confluent green spots and warts on the flots of the same colour, those of the intervals red, the spaces between bicoloured. The third is particularly distinguished for its size, being much less than the others. This of all the European toads seems to be the most universally known. It is found in shady places, in gardens, woods, and fields, and frequently makes its way into cellars, or any obfure recelues in which it may occasionally conceal itself; and where it may find a supply of food, or a security from too great a degree of cold. In the early part of spring, like other of this genus, it retires to the waters, where it continues during the breeding season, and deposits its ova or spawn in the form of double necklace-like chains or filaments of beautifully transparent gluten, and of the length of three or four feet, in each of which are disposed the ova in a continued double series throughout the whole length, having the appearance of so many small jet-black globules or beads; being in reality no other than the tadpoles or larve convoluted into a globular form, and waiting for the period of their evolution, or hatching, which takes place in the space of about fourteen or fifteen days, when they break from the surrounding gluten, and like the tadpoles of frogs, swim about in the water, and are nourished by various animal stools, gluten, leaves of water-plants, &c. &c. till, having arrived at their full growth, the legs are formed, the tail gradually
gradually becomes obliterated, and the animals leave the water, and betake themselves to the surface of the ground. This generally happens early in the autumn, at which period it is not uncommon to find such numbers of the younger animals in some particular places, that their appearance has frequently given rise to the vulgar idea of their having been flowered from the clouds.

The toad is an animal too well known to require any very particular description of its form. It may be necessary to observe, that it is always covered by tubercles, or elevations on the skin, of larger or smaller size in different individuals, and that the general colour of the animal is an obscure brown above, much paler and irregularly spotted beneath. The toad, however, is occasionally found of an olive cast, with darker variegations; and in some specimens, more especially in the earliest part of summer, the shoulders and limbs are marked with reddish spots, while a tinge of yellow often pervades the under parts both of the limbs and body.

The toad arrives at a considerable age; its general term of life being supposed to extend to fifteen, or even twenty years; and Mr. Pennant, in his British Zoology, gives us a curious account, communicated by Mr. Arscott, of Teholt, in Devonshire, of a toad’s having lived, in a kind of domestic state, for the space of more than forty years, and of having been, in a great degree, tamed, or reclaimed from its natural fufpicion or desire of concealment; since it would always regularly come out of its hole at the approach of its master, &c. in order to be fed. It grew to a very large size, and was considered as singular in curiosity, that even ladies, laying aside their usual averter and prejudices, requelled to see the favourite toad. It was, therefore, often brought to table, and fed with various insects, which it seized with great avidity, and without seeming to be embarrassed by the presence of company. This extraordinary animal generally refrained in a hole beneath the steps of the house door, fronting the garden; and might probably have survived many years longer, had it not been severally wounded by a raven, which seized it before it could take refuge in its hole, and notwithstanding it was liberated from its captor, it never again enjoyed its usual health, though it continued to live above a year after the accident happened.

The toad is looked upon with great averter by the major part of mankind; and it must be confessed, that its appearance is disgusting, yet the eyes are remarkably beautiful, being surrounded by a reddish gold-coloured iris, the pupil, when in a state of contraction, appearing transverse.

We shall conclude the history of this animal, with mentioning the very extraordinary circumstance of its having been occasionally discovered included, or imbedded, without any visible outlet, or even any passage for air, in the subflance of wood, and even in that of stone or blocks of marble. “For my own part,” says Dr. Shaw, “I have no hesitation in avowing a very high degree of scepticism as to these supposed facts; and in expressing my fulpictions that proper attention, in such cases, was not paid to the real situation of the animal. That a toad may have occasionally laticubalised in some part of a tree, and have been in some degree overaken or inclosed by the growth of the wood, so as to be obliged to continue in that situation, without being able to effect its escape, may perhaps be granted; but it would probably continue to live so long only as there remained a passage for air, and for the ingwrs of insects, &c. on which it might occasionally feed; but that it should be completely blocked up in any kind of stone or marble, without either food or air, appears entirely incredible, and the general run of such accounts must be received with a great many grains of allowance for the natural love of the marvelous, the fuperprize excited by the sudden appearance of the animal in an unsuspected place, and the consequent neglect of minute attention at the moment, to the surrounding parts of the spot where it was discovered.”

Rubeta; the Natter Jack. Of this the vent is obtuse; and it has a yellow line on the back; the body beneath is spotted with black, but above it is of a dirty yellow, clouded with brown, and covered with porous pimples of unequal sizes. This species frequents dry and sandy places, and is found on Putney Common, and near Revereby-Abbey in Lincolnshire, where it derives its trivial name. It never leaps, neither does it crawl, with the slow pace of a toad, but its motion is more like running. Several are frequently found together, and like others of the genus they appear in the evening.

Gibbosa; Gibbous Toad. Body oval, convex, with a longitudinal cinereous dentate band. A variety has its back marbled with red and yellowish-aih; the belly is yellow, spotted with black. The first is found in diverse parts of India, the second at Surinam.

Bomina; Laughing Toad. Belly orange, spotted with sky-blue; the pupil is triangular. Gmelin gives three varieties of this species: viz. 1. That which is distingusihed with a black belly, marked with clear white spots and points. 2. One which is brown with white spots; the sides and round the joints are red. 3. One which is distinguished for its loud honorious voice. It is found in the fanny parts of Germany and Helvetia; leaps like a frog; emits a clear sound like a man laughing: it is a good deal resembles the common toad, but is smaller, black, and every where rough, with dots on the upper part, and variegated beneath, with transverse wrinkles beneath the neck.

Salsa; Salt Toad. Above of a dirty olive colour, but beneath it is white, spotted with black. This species is found in the stagnant waters of Berchtesgaden, and is less than the R. arborea, hereafter to be noticed; it avoids the light, is inodorous, and emits no liquid from its minute perforated warts: the legs are marked with brown bands, beneath it is yellow.

Ventricosa; Tumid Toad. The mouth of this is semifossorial, and the throat ovate. A variety is marked with pale white puflules. It is found in South America, and in some parts of India. The body is brown and orbicular; the tubercules on the top of the neck longitudinally dilated; the back has three longitudinal wrinkles; the flanks are tumid and dilated.

Marina; Marine Toad. Shoulders tumid; eye-lids warty, concave; the hind feet are subpalmate; there is a variety, which is spotted with brown; beneath it is shaded with livid, the neck and shoulders are spotted with grey. This is found in various parts of America, and is more than six inches long. Its body is yellowish-grey, with a few rather tawny spots: the warts are distinguished with an elevated bar spot in the middle: the protuberances of the shoulders are oval, smooth, and porous; the vent is surrounded with wrinkled radii; the hind toes are connected only as far as the first joint, the last joint is fringed with a scaly membrane.

Brasilensi; Bratil Toad. Yellowish-aih, with red waved spots, beneath smooth.

Arumco; Chili Toad. All the feet of this species are palmate. It inhabits, as its name imports, the waters of Chili: in its size it resembles the R. temporaria described below: on the hind toes there is a flight appearance of claws.

Lutea;
LUTEA: Yellow Toad. The body of this is yellow; all the feet are subpalmate. This is also found in Chili, and much resembles, in its habits, the R. eculenta, but is much less; the falt joints of the toes are not connected.

MARGARITIFERA: Pearled Toad. Body brown-red, sprinkled with pale red spots.

CORNUTA; the Horned Toad. This takes its specific name from the circumstance of having its eye-lids horned. It inhabits Virginia and Surinam, and of the whole tribe it is the most deformed. It is said, indeed, to surpafs all animals in ugliness. It is thus described: The head is large, and rounded before; the mouth is excessively large; the eye-lids are soft, mucronate, trifid at the point; the eyes are seated in the middle; the body is of a greenish-brown, with broad longitudinal whitifh stripes on the back; the legs are transverfly faciace with brown; when full grown, the back, the thighs, and vent, are fpyne.

STIBUNDA; Defart Toad. The specific character is, that above it is ahny-glucous, varied with blackish-green spots, beneath of a dirty white; the hind feet are semi-palmate, with the appearance of seven toes. It inhabits the dry defarts near the Ural, sometimes hides itself in holes, and Crawls out in the evening; it resembles the common toad, but is nowehere larger.

VESPERTINA; Siberian Toad. This has a transverse line between the eyes, forked behind, and other spots running obliquely from the eyes to the nose; the body above is cinereous, with longitudinal subfuscous brown spots, varied with different shades of green; beneath it is daifted with a whitifh-atl. As its trivial name imports, it inhabits Siberia, and is about the fize of a common toad; it leaps flowfly: the head is short; the body above is sprinkled with subwartv papille.

RUDIBUNDA; Jocular Toad. Body brown, spotted above with cinereous; the dorfal line is yellow, or greenish; beneath it is smooth, whitifh; haunches brown, spotted with milk-white. The head of this species is broad; the upper eye-lid is convex, sprinkled with pores; the apertures of the ears are flat; the back is porous; the fides are marked with obfolete warts; the fore thumb is divaricate, thick at the base; the next toe shorter than the refl; the hind limb subfaiiate; the hind feet have a callus within, refembling a fith toe; the toes have a wart beneath, near the joints.

This species is found in great numbers near the rivers which empty themselves into the Caipain fea; it never ventures on the dry land; it is very large, and frequently weighs more than half a pound; it refembles the R. temporaria, but is broader and shorter; its voice in the evening is like that of a man laughing.

VARIABILIS; Changeable Toad. Colour variable; back and fides gibbous; warts yellowish in the centre; it is very small on the middle of the back, and larger on the most prominent part of the fanks. It inhabits the flawy places in Germany, and is only about two inches long: in its habits, it holds an intermediate place between the toad and frog; when full awake its body is white, with green spots; in the heat of the sun it is entirely cinereous; when asleep, the fots are only cinereous, and when torpid the body has a fhef-coloured cut.

The head is rounded, and the mouth without teeth; the margin of the upper jaw is doubled; the tongue is flefy, thick, placed far back, the bafe obscurely bind, very entire at the tip; it has hardly any upper eye-lid, the lower one is folding; cavities of the ears white; the warts reffemble teats, very numerous on the groin; the chin is marked with prominent dots; the colour, when preferred in spirits, is yellowish, and above it is of a pale olive; the fore feet are three-toed, beneath they are emarginate, the thumb is larger; the second toe of the hind feet is very long.

Section B.—Body more oblong, smooth; Legs longer. Frogs.

Species.

TYPHONIA; Hurricane Frog. Of this species, the diftinguifhing characterifit is, that the lobes of the ears are oval. It inhabits America, and is faid to make a noiful croaking before hurricanes and whirlwinds. The back is marked with four longitudinal wrinkles, elevated points, and black spots; the hind toes are narrow, without claws, the second is very long.

PENTADACTyla; Mackarel Frog. All the legs are fificate, five-toed; body veined, the dorfal ftripes transverfly, the lateral ones are ocellate. There is a variety which is brown; the fore feet have four toes, with the rudiment of a fifth; the hind feet have five toes, with the rudiment of a fith.

OCELLATA; Ocellate Frog. The ears are marked with an ocellate ftip; feet with claws, the hind ones sub-pal- mate. It inhabits America.

Piplis: Glamorous Frog. This is green, with numerous ocellate spots, surrounded with a yellowifh ring. This species is smaller than the green frog, but, in its general habits, it bears a confiderable refemblance to that animal. It is a native of North America, and frequents rivulets and ditches of water, and is fo strong and vigorous, that it is faid it can leap to the distance of five or fix yards. In the spring and beginning of summer, it is faid to indicate the approach of rain by the peculiar sound which it emits. In the living animal the ears are of a shining yellow colour; the region of the anus is very much wrinkled; the third fore toe from the thumb longer than the refl; the body refembles that of the eculent, or green frog, but the hind thighs are longer; the fanks are longer still, and hind feet are longer than thefe, marginate on each fide; the toes are connected nearly to the tip, the fourth is longer than the refl.

Bicolor: Blue and Yellow Frog. Colour blue, ochreous beneath, feet unwebbed; toes flattened and orbicular. This elegant species is of a moderate fize; it measures more than four inches in length. The whole of the upper surface is of a beautiful blue, while the under parts arc of a pale orange, or ochre colour. The head is large, the mouth wide, and the tip of the nose truncated. All the toes are furnished with a large orbicular tip, and beneath each of the joints there is a pecuf or tubercle. The upper parts of the female have a deeper shade of violet than thofe of the male. It is fuppofed to be a native of Surinam.

Maxima; the Great Frog. All the feet are palmate, as well as the toes, fificate; body veined and variegated; the tip of the back obliquely fotted. Bands of the legs in pairs, approximate, above confluent.

Alpina; Alpine Frog. This is entirely black, and inhabits the declivities of the mountains in Austria.

Venulosa; Veined Frog. Feet efl; the body veined with confluent ftips. It inhabits India and South America.

Virginica; Virginian Frog. Cinereous, spotted with red, beneath it is yellowifh; the back is five-angled, with as many ftipes. It is found in Virginia.

* Temporaria; or Common Frog. The back of this is flatifh and sub-angular. There is a variety, which is of a dirty olive colour, with large warty ftips, the head above plain, beneath whitifh; twice the size of the common frog. Both are found in this country, and the latter also in Persia; it lives, during the spring, in water, among toads, and in the summer.
The frog is a very useful animal, this is mostly in connection with the edible nature of its eggs, which are not only considered highly nutritious by the French nation, but are also a primary item in the diet of many countries around the world. The egg is of a semi-translucent olive-brown color, with a somewhat sticky texture that can adhere to the surface of leaves or other objects, rendering them difficult to collect. As the egg hatches, it transforms into a delicate tadpole, more difficult to observe due to its translucent nature, which is crucial for its survival. Upon emerging from the water and reaching a length of about an inch, the tadpole begins its metamorphosis, transitioning into a juvenile frog. This process is marked by a series of changes in its skin, body, and appendages, making it an essential part of aquatic life. Despite the presence of aquatic vegetation and animals, the frog maintains a delicate balance, ensuring its survival in these environments.
young birds of different kinds, mice, and even ducklings, and, as it does with the rest of its prey, swallowing them whole. At the end of four years it has reached its full growth. It begins to breed the year following, and the period of its life is sometimes extended to sixteen years.

**Australasiæ;** Australian Frog. The body of this is brown above, beneath blueish; the flizes are speckled with ochre colour; the toes of the fore feet are light. It inhabits New Holland. The second toe of the hind foot is very long; the claws are red.

**Paradoxæ;** Paradoxical Frog. This is of a yellowish and olive colour, variegated with rufous bands; the hind legs or thighs are obliquely streaked.

In its general form this species resembles the *R. temporaria.* The oblique longitudinal stripes on the hind legs constitute the principal mark of distinction. There are four toes on the fore feet, and they are unwebbed; the hind feet have five toes, and are deeply palmated to the very ends of the toes. Near the short toe there is an oblong callos, forming a spurious one. The upper jaw is becft with a row of small denticulations. This species is a native of South America, and is more common in Surinam than in other places.

Naturalists, says Dr. Shaw, have been extremely puzzled with regard to the true nature of what has been taken for the tadpole of this frog. At one time it was considered by Linnaeus as a species of lizard, and therefore arranged by him under the genus Lacerta. At another time he has placed it under the present genus, with the specific name piceus. It was described by Edwards under the denomination of the frog-fish of Surinam. The structure of the animal, which has been the subject of so much discussion, shews clearly that it is the larva or tadpole of a frog; and it is supposed, with no small degree of probability, that the differences in the accounts given of this animal by naturalists have arisen from the different stages of its progress, in which it has been found. But as this tadpole is so much larger in size, in proportion to the perfect animal, than any other species yet known, it may be the larva or tadpole of some of the larger species, and not that of the *R. paradoxa,* which is but a small frog.

**C. Hind Feet very long; the Claw fruticulata.**

**Arborea;** Tree-Frog. The body of this species is green, beneath granulate; feet cleft. Gmelin enumerates five varieties of this species. 1. Those which have four toes to their fore feet, and five to those that are behind; the knees are warty beneath. 2. Those that are of a green colour, with a straight yellow line on each side. 3. The body of this variety is reddish. 4. Of this it is brownish-green. 5. The fleredennes of the body marks this variety.

"In the beauty of its colours," says Dr. Shaw, "as well as in the elegance of its form, and agility of its movements, the tree-frog exceeds every other European species. It is a native of France, Germany, Italy, and many other European regions, but is not found in the British islands. Its principal residence, during the summer months, is on the upper parts of trees, where it wanders among the foliage in quest of insects, which it catches without extreme celerity; feeding softly towards its prey, in the manner of a cat towards a mouse, and, when at the proper distance, seizing it with a sudden spring, frequently of more than a foot in height. It often suspends itself by its feet, or abdomen, to the under parts of the leaves; thus continuing concealed beneath their shade. Its size is smaller than any European frog, except the *R. bombina.* Its colour, on the upper parts, is more or less bright in different individuals; the abdomen is whitish, and marked by numerous granules; the under surface of the limbs is reddish; and the body is marked on each side by a longitudinal blackish or violet coloured streak, separating the green of the upper parts from the white colour of the lower; the inferior edge of this dark lateral stripe is tinged with yellow. The body is smooth above, and moderately short or plump; the hind legs are very long and slender; the fore feet have four, and the hind feet five toes, all of which terminate in rounded, flat, and dilated tips, the under surface of which, being soft and glutinous, enables the animal to hang with perfect security from the leaves of trees, &c. The skin of the abdomen is also admirably calculated by nature for this peculiar power of adhesion, being covered with small glandular granules, in such a manner as to fallen closely even to the most polished surface; and the animal can adhere at pleasure to that of glass, in whatever position or inclination it be placed, by merely pressing itself against it.

Though the tree-frog inhabits the woods during the summer months, yet, on the approach of winter, it retires to the waters, and there submerging itself in the soft mud, or concealing itself beneath the banks, remains in a state of torpidity; and again emerges in the spring, at which period it deposits its spawn in the waters, like the rest of this genus. The male at this period inflates its throat in a surprising manner, and exerts a very loud and sharp croak, which may be heard to a vast distance. The spawn is deposited about the end of April, in small clustered masses; the inclosed globules or embryos being of a pale yellowish-brown colour. The tadpoles become perfect frogs, by the total decay of the tail, about the beginning of August; and soon begin to ascend the neighbouring trees, where they continue to reside during the remainder of the warm season; so do likewise the parent animals, after the breeding season is past. During their residence among the trees, they are observed to be particularly noisy on the approach of rain; so that they may be considered, in some measure, as a kind of living barometers; more especially the males, which, if kept in glaesses, and supplied with proper food, will afford an infallible pre- lage of the changes of weather.

**Leucophylæ;** White-spotted Frog. Body smooth, hoary, with oblong milk-white spots; the fore feet are lobate, the hind feet palmate. It inhabits America, and weighs only about forty-six grains. Eyes of a fine golden colour, and between these, on the sides and middle of the back, there are oblong white spots; the lauches are slender.

**Squintigeræ;** Scaly Frog. In this a fealy band reaches half-way round the back; the sides and throat have folds; the fore feet are semi-palmate, the hind feet are palmate. This is about two inches long, and is supposed to be an inhabitant of America. The body is variegated with grey and brown in thick aggregate specks, and a few spots down the hind part of the back, in a serpentine direction; the band confists of minute, sub-pellucid, rhamboidea, imbricate scales; the hind limbs are twice as long as the fore.

**Boans;** Croaking Frog. Body smooth, with continuous dots beneath; feet palmate. There are two varieties. 1. The body above is of a blueish lead-colour. 2. The body of this is inclining to orange. It is found in America, and differs only from the tree-frog in having the feet webbed, and the body marked with white spots.

**Rana Arborea, the Tree-Frog.** See *Ranunculus Fruticosus* and the preceding article.

**Rana Piscator.** See *Lophius Piscatorius,* and Sea-Devil.

RANA-
RANARIDIL, in Geography, a town of Austria; 11 miles S. of Aigen.

RANASAGUR, a town of Hindooftan, in Bahar; 18 miles W. of Arrah. N. lat. 25° 37'. E. long. 84° 31'.

RANCAGUA, a jurisdiction of South America, in Chili. It derives its name from the inhabitants living in single houfes, without the appearance of a viflage; every family lodging in their lonly cottage, four, fix, or more leagues from each other. It is not, however, without a capital, consisting of about 50 houses, and between 50 and 65 families, mofl of them being Meftizos, though their calf is not perceivable by their complexion. The whole Jurifdiction may contain about 1000 families, Spaniards, Mef- tizos, and Indians. Unloa's Voyage, vol. ii.

RANCE, Armand-Johm le Bouthiller de, in Biography, the initiator of the order of La Trappe, was of noble defcent, and born at Paris in the year 1526. At a very early period he exhibited an extraordinary genius for classical and polite learning; and at the age of 10 he had read many classical works, in the Greek as well as the Latin languages, and is said at that early period to have under- 

flood Homer. When he was only 13 years of age, he prepared for the prefs a new edition of Aulacreon, with notes, that displayed confiderable talent and reafon. This was publifhed in 1639. Four years previously to this, he had received the clerical tonsure, and had been nominated a canon of Notre Dame at Paris. He was promoted by the king to the fumecry priory of Boulogne, near Chambor; and he was fubfequently promoted to three different abbies, among which was that of La Trappe, and to other places of honour and trull in the church. He fludied divinity at the Sorbonne, and in 1651 he was ordained priet; and in feconds three years, the degree of doctor of divinity was conferred upon him by the faculty of the Sorbonne. Having thus completed his studies, he entered into the world, and, like one broken from his shackles, he devoted himself eagerly to its honours, pleasures, and gaieties. Hefoon became a favourite at court, and was appointed almoner to the duke of Orleans, and one of the deputies of the second order in the assembly of the clergy in 1655. On a sudden, and for a caufe that never was well understood, he became dilighted with the world, and resolved to renounce for ever its pleasures, enjoyments, and vanities. Nofooner had the abbé de Rance formed the resolution than he withdrew to his eflate in the country, to deliberate concerning the mode of life which he should pufh. Having made up his mind to embrace the monafical life, he fold his eflate, and befowed the money which it produced on the Hôtel-de-Dieu at Paris. He also reneged all his benefices and dignities, excepting his priory of Boulogne, and the abbey of La Trappe; the latter of which he retained by a special permission of the king, in order to introduce into it a reformation of the fu- tures and discipline. He took the habit, and made his pro- feffion in the year 1664, and spent about establishing the gloomy and outrafe discipline of monafery in its full perfe- 

ction. The princeiftit itself feemed peculiarly adapted to the horrid fystem which he eftablifhed, being the most gloomy, barren, and defolate spot in the whole kingdom of France. Here the days of the monks were conftantly spent in prayers, tears, contemplation, silence, the perusal of holy books, the hardfhips of bodily labour, and the practice of the most rigid authorities. All other deigns and occupations, how- ever laudable and excellent in themfelves, they were to re- 

gard as vain and fufpicious of perfons of their order. The leaf relaxation, or amufement of the moft innocent nature, they were not allowed; and they were prohibited from engaging at all in literary fudies. Strange! that a mind flourifh with liberal knowledge, and diftinguifhed by good taste, fhould have been fo far perverted by fuperition and fanfaticism, as to devote or faneft such regulations.

That the world might be acquainted with the discipline of his community, he published "A Treatife on the Sanftity and Duties of the Monaftic State." As de Rance advanced in years, the severe discipline to which he ftrictly conformed, rendered him fo infirm, that, finding himfelf unequal to the duties of his poft, he refigned it into the king's hands, but was permitted to appoint his Successor. At length, worn out with infirmities and mortifications, and lying on a bed of ahles and fraw, he died in 1700, in the 74th year of his age. He was author of a great number of theological and other pieces, among which may be men- 

RANCE, in Geography, a river of France, which runs into the sea near St. Malo.

RANCHAN, a small ifland near the coast of Darien, in the Pacific ocean.

RANCHERIA, a town of South America, in the vice- 

royalty of Granada, and province of St. Martha; 20 miles N.E. of Hacha. N. lat. 11°. W. long. 72° 36'.—Alfo, a small ifland in the Pacific ocean, near the coast of Veragua. N. lat. 7° 50'. W. long. 82° 16'.

RANCHERIAS, a name given, in the province of Panama, to assemblages of Indian huts under the jurifdiction of a village. These rancherias are situated to the south- 

ward, in the small chafms or breaches of the mountains.

RANCID, in Rural Economy, from the Latin rancidus, of rancio, to be rank, a term applied to substances, which have contracted a ftrong offensive smell and taste by keeping, as bacon, butter, and all fat fubstances are apt to do. It would be a very ufeful discovery, to find out any ufly fimple method of preventing this efrect from taking place.

RANCON, in Geography, a river of France, in the de- 

partment of the Lower Seine, which runs into the Seine, at Caudebec.—Alfo, a town of France, in the department of the Upper Vienne; 8 miles E. of Bellac.

RANCONET, Aimar de, in Biography, a learned and 

worthy magistrate, who flourifhed in the 16th century, was born at Bordeaux, in which city his father was an advocate of parliament. Having received the advantages of a good education, he became deeply fkillfed in the Roman law, to the fudy of which he joined that of philofophy, mathem- 

atics, and antiques. Having been some time a coun- 

fellor in the parliament of Bordeaux, he was raised to the poft of prefident of the fourth chamber of inquifition in that of Paris. The religious contentions of the time were fatal to him. When the cardinal of Louvain alfembled the parliament of Paris, to procure its opinion concerning the punishment of heretics, Rancoet brought the works of Sulpicius Severus, and read aloud the passages in which that writer cenfures the execution of Prifitian; upon this the prefident caused him to be imprisoned in the Baffile, where he died of grief in 1559, at the age of 60. His latter days had been singularly unfortunate. He was reduced by want to be a correcteur of the prefs to the Stephens; he faw his daughter die on a dunghill, and his fon executed, and his wife was killed by lightning. This learned man published fearcely any thing in his own name, but contributed much to the labours of others. He is faid to have had the chief part in the valuable treatife, "De Verborum Signifi- 

catione," and in the "Formula" of Briffon; and Pithou asserls,
affected, that he compiled the Dictionary that bears the name of Charles Stephens. He wrote "Le Trefor de la Langue Françoise, tant ancienne que moderne," Moreri.

RANCONNIERES, in Geography, a town of France, in the department of the Upper Macon; 9 miles W. of Bouronne.

RANDAL, Dr. John, in Biography, organist, doctor in music, and music professor in the university of Cambridge. He was brought up in the king's chapel, was one of the children of that choir who first performed in Handel's oratorio of Esther, at the house of Bernard Gates, master of the boys in James-street, Westminster, on Wednesday, February 23, 1731, when it was performed in action, previous to its having been heard in public, or any where but at Cannons, the magnificent seat of the duke of Chandos, for whose chapel it was composed in 1729.

Randal was never rated very high in his profession; he was regarded as a slight organ-player, and had never distinguished himself as a composer. He obtained his degree at the installation of the duke of Grafton in the university of Cambridge, for which he composed the ode written by Mr. Gray, to the embellishment of all the musical profession, by undertaking to have it performed by the musicians resident in the university, without putting his grace to the expense of additional hands and voices from London, as Drs. Greens and Boyce had thought necessary on former occasions at Cambridge, and Dr. William Hayes at Oxford.

As Dr. Randal's professional life was unmarked by talents, his death, which happened in 1799, was hardly noticed, except by the candidates for the professorship, and his organist's places.

RANALSTOWN, in Geography, a post-town of Ireland, in the county of Antrim, in the neighbourhood of which is Slanes castle, the seat of lord O'Neill. It is situated on the river Maine, to the northward of lough Neagh. Randallstown is 4 miles N.W. from Antrim, and 85 N. by W. from Dublin. Before the union, it was represented in parliament. Carlile, &c.

RANANS, a town of France, in the department of the Puy-de-Dôme, and chief place of a canton, in the district of Riom; 12 miles N.E. of Riom. The place contains 1047, and the canton 7966 inhabitants, on a territory of 130 kilometres, in 11 communes.

RANASALMI, a town of Sweden, in the government of Kuopio; 52 miles S. of Kuopio.

RANDAZZO, a town of Sicily, in the valley of Demona; 35 miles W. of Taormina. N. lat. 37° 57'. E. long. 15° 4'.

RANDEER, a town of Hindoostan, in Guzerat, on the Taptes, opposite to Surat.

RANDEGG, a town of Austria; 8 miles N.E. of Bavarian Waidhoven.

RANERADT, a town of France, in the department of the Roer; 10 miles N.W. of Juliers. N. lat. 50° 59'. E. long. 6° 8'.

RANDERS, a town of Denmark, in North Jutland, on the Gulden. This town is reduced, and has now only one parish church, a grammar-school, an hospital, and a chapel near the town. The chief articles of trade consist of leather gloves, salmon, earthen-ware, and strong beer. It was formerly well fortified; 20 miles E. of Viborg. N. lat. 56° 28'. E. long. 10° 3'.

RANDERSACKER, a town of the duchy of Wurzburg, on the Main; 2 miles S. of Wurzburg.

RANDIA, in Botany, was so named by Houttuyn and Linnaeus, in honour of Mr. Isaac Rand, F.R.S., an apothecary in London, who filled the place of Lecturer and demonstrator of botany in the Chelsea garden, from the year 1722 to 1739. He published in 1730 an octavo index of the official plants of that collection, 518 in number, specifying the part of each used in physic. He also printed, in 1739, a general catalogue of the Garden. His name often occurs among the botanists of that period. The Randia, however, of which two supposed species are defined in Linn. Sp. Pl. 213, 214, by the names of miltis and aculeata, both West Indian shrubs, is now sunk in Gardenia; see that article, where we have suggested a doubt, possibly not well founded, of the propriety of this measure. Both species of Randia are united by Willdenow, Sp. Pl. v. 1. 1230, on the authority of Swartz, as well as in Ait. Hort. Kew. v. 1. 370, under the name of Gardenia Randia. This plant, sent by Houltown to Miller, before the year 1735, does not appear to exist in our flaves at present. Its form may be seen in Browne's Jamaica, 143, t. 8. f. 1. That author says the pulp of the berries flains paper or linen of a fine permanent blue, which refists the action of soap and of acids. The shrub is frequent in the low lands of Jamaica, on the soil barren clay soil.

RANDBNITZ, in Geography, a town of Bohemia, in the circle of Schlan; 12 miles N.N.E. of Schlan. N. lat. 50° 25'. E. long. 14° 24'.

RANDOLPH, Thos., in Biography, an English poet of great celebrity, was born at Newsham, in Northamptonshire, in 1605. He was educated at Wrekinster school, and having completed his course, he was elected to Trinity college, Cambridge. He shewed an early turn for poetry, and at ten years old wrote "The History of the Incarnation of our Saviour," in verse. He acquired an unfortunate, and, to him, a fatal habit of conviviality, which diverted him from the pursuit of any profession, and which led him to waste his scanty patrimony, and his health, in the company of wits and men of pleasure in the metropolis. He died in his 35th year, to the great regret of those who admired his poetry and loved his company. He possessed an excellent genius, and had his life been extended, it has been thought he might have attained to a very high rank among the poets of his age. His miscellaneous poems were collected after his death by his brother, who published them at Oxford, in 1640. They have been, but not of late years, several times reprinted. He likewise composed six dramatic pieces of the comic class, one of which, "Hey for Ho-ney, down with Knavery," was taken from the Plitus of Aristophanes. His pieces are said to be some of the best in the manner then prevalent, which consisted in playing with words and thoughts, and connecting remote ideas by fanciful allusions. His expressions are often elegant, and his verses harmonious. His friend, Sir Christopher Hatton, caunted, at his own expense, a monument of white marble to be erected over his grave, the inscription on which, in Latin and English verse, was made by Peter Haulton. Biog. Brit.

RANDOLPH, John, a learned prelate of the church of England, descended from a respectable family in Kent, was born July 6th, 1749. He was the younger son of Dr. Randolph, formerly president of Corpus Christi college, Oxford, who died in March 1783, after having presided over the college for the long space of 35 years. The president's father was rector of Canterbury, and had several sons, among whom was Dr. Francis Randolph, principal of Alban Hall, Oxford. The whole family have been remarkable for their orthodox zeal and attachment to the established religion of the country. The subject of this article became a student of Corpus Christi college, Oxford, where he took his several degrees, at that of D.D. he had by diploma in 1783. Previously
viously to this he had been appointed prelector of poetry, proctor, and in 1782 Regius professor of Greek. In this same year he was made prebendary of Salisbury, canon of Christ-church, and Regius professor of divinity; and in 1783 rector of Ewelme. In 1790 he was elevated to the bishopric of Oxford, from which he was translated to that of Bangor in 1807, and then to the metropolitan see of London in the year 1819. Notwithstanding these high preferments he passed a great part of his life in the university of Oxford, and it was generally believed that when he was elevated to the see of Oxford, the university was complimented with the nomination by the crown. His lordship was author of many sanguine sermons, and lectures delivered on different occasions: e.g. of "De Graeco Lingua Studio Praedicto habitant Schola Linguniaria," 1783.; and "Concio ad Clerum in Sano Provinciâ Cantuariensi Provincia ad D. Pauli," 1790. His lordship was a zealous promoter of the National schools in opposition to those founded by Lancafter, and he was understood to be a violent opponent to the bible society, and to the spread of what has been termed Scætarism. One of his last works was a Report of the Progress made by the National Society, to which the general committee referred in terms of gratitude, at their first meeting after his lordship's decease, in the following terms; "whose latest employment had been to raise, for the information of the public, the progress of a work of which he had contributed his time, his labour, and his counsels, the committee could not fail to entertain a common sentiment of profound regret for the loss which they have sustained, and to cherish in their minds the liveliest recollection of the service which has been so successively fulfilled by him in this second report. They wish, therefore, to add to this document, designed for general circulation, their sense of what is due from the public, and themselves, to the memory of one who was a constant and ardent promoter of this laudable institution, from its first establishment to the last hour of his life.—The committee, in this testimony, though limited to a single object in the large field of pastoral duty in which he incessantly engaged, may serve to denote the benefits which have resulted from his prompt, unwearied, and effectual exertions." The following is the character drawn of him by Mr. arch-deacon Jeffery, and which alludes to his zeal for the church of which he was an active member. "Faithful now of being confirmed for mercenary auluation, or reproved by unconscious merit, a just tribute may be paid to the character of that departed and exalted prelate, who is, and will be, most lamented where he was best and most entirely known. This opportunity, therefore, is willingly embraced of offering a heart-felt condolence to the ministry of the diocese on the affecting and important loss, which, in these perilous times of contending feuds and unsettled opinion, has arised to them, and to the church:—To them, in the premature privation of a diocesan, firm in his support of ecclesiastical authority, but considerate in its application; eminently verified in the letter of ecclesiastical law, but liberal in its practical construction, reluctant in interference, but determined in duty, flow in the profession of service, but prompt in its execution; disinterested in patronage, unwavering in measures, correct in judgment, attentive in counsel, and kind and compassionate to distresses:—To the church, in the premature privation of a father, diligent in her rites and services, but unobstinate in piety and devotion; found and unrelaxing in her doctrines and faith; but diligent in discovering her interests, ever forward in affording her privileges, and ever able in the assertion and the defence." The bishop died suddenly on the 28th of July 1813. He was one of the governors of the Charter-house; trustee of the British Museum; dean of the Chapel royal; visitor of Sion college; and provincial dean of Canterbury; Gent. Mag.

RANDOLPH, in Geography, a poll-town of America, in Massachusetts, formed of the S. precinct of Brantree, in Norfolk county, in the year 1783; 15 miles S.E. of Bolton. The inhabitants are mostly farmers, but manufacture large quantities of shoes for market.

RANDOLPH, a county of Hillborough district, in North Carolina, bounded N.E. by Orange, and N.W. by Guildford. The number of inhabitants is 10,112, and they are mostly Quakers; the other denominations are Presbyterians, Baptists, Methodists, and Universalists. Their good land produces 40 or 50 bushels of Indian corn, or 20 of wheat, per acre. The chief town is Ashborough.

RANDOLPH, a county of Virginia, bounded N. by Montgomery, and S. by Pendleton. The number of inhabitants is 2854.

RANDOLPH, a poll-town in Orange county, Vermont, being the 4th town W. of Thetford, on Connecticut river. The number of inhabitants is 2255. White river, by its two branches, waters the E. and W. side of the town. It has a large bed of iron ore, two forges, and a flitting mill. The congregational meeting-house has a reepee, and is large; 47 miles from Rutland.

RANDOLPH, a county of Indiana territory.

RANDOLPH, a town of Morris county, in New Jersey, containing 1771 inhabitants.

RANDOM, a township of Essex county, in Vermont, W. of Brunwick.

Random Island, a small island in Trinity bay, near the E. coast of Newfoundland. N. lat. 48° 15', W. long. 53° 45'.

Random-Ship, a shot made when the muzzle of a gun is raised above the horizontal line, and is not designed to shoot directly, or point-blank.

The utmost random of any piece is about ten times as far as the bullet will go point-blank; and the bullet will go farther when the piece is mounted to about forty-five degrees above the level range.

The space or distance of the random is reckoned from the platform to the place where the ball first grazes.

Random, in Geography, a river of Brandenburg, which runs into the Ucker; three miles S. of Uckermunde.

Rands, a lake of Norway, in the province of Agder-bus, 35 miles long, and two broad; 20 miles N. of Christiania.

Randsberg, a town of Sweden, in Well Gothland; 76 miles E. of Uddevalla.

Randychoar, a town of Boatan; 18 miles N. of Beyhar.

Ranea, a town of Well Bothnia; 60 miles W. of Torneca.

Ranelagh, Rotunda and Gardens, built and opened for musical performances and public amusements in 1742. The building was erected in the spacious garden belonging to the residence, at Chelsea, of lord Ranelagh, one of the ministers of Charles II., when paymaster of the army.

It was planned by the late Mr. Lacey, afterwards joint-patentee of Drury-lane theatre with the great actor Garrick. At the first opening of this magnificent building, several experiments were made in placing the orchestra, in filling it, and in the time of performance, before it was settled as an evening promenade. The orchestra was at first placed in the middle of the rotunda. The performance was in a morning; and oratorio choruses chiefly furnished the bill of fare. Sir John Barnard, complaining to the magistrates, that
RAN

that the young merchants and city apprentices were frequently seduced from their counting-houses and shops by these morning amusements, they were prohibited, and the doors opened at six o'clock in the evening. The performance, however, did not begin till eight o'clock, but was ended at ten.

It was intended to rival Vauxhall, and was little injured by bad weather; as the company, at such times, had a safe and pleasantr retreat into the rotundas, and as few went thither but in carriages.

Its success as an evening's amusement remained undiminished more than 40 years. It was ruined by the late hours to which it was gradually brought by fine folks, who, at length, never came thither till past ten o'clock, when the musical performances were over, and sober people used to return home before eleven o'clock to their supper, which enabled them and their servants to go to bed, and rise, at their accustomed time.

But, at length, perfons of rank and fashion made a de-bauc of this innocent amusement, and went to it and departed from it as late as at a masquerade. This precluded all that had any thing to do themselves, or any employment for their servants in the morning, and so much refined the company, that at midnight there had been seldom sufficient money received at the entrance, to cover the expenses of the lamps, the terms of admission being only 3s., for which, besides a good concert by the bell performers in London, the company was furnished with excellent rolls, butter, and tea. In the year 1809 it was shut up, and only used occasionally for a masquerade, a festival, or an exhibition of fire-works. But since the period just-mentioned, the building has been pulled down, and the materials sold piecemeal, as was the case at Cannons, the splendid mansion of the duke of Chandos, (or Palazzo, as it would have been called in Italy,) and the ground is now (1809) of no other utility than occasionally to drill and exercise the Chelsea volunteers.

RANES, in Geography, a town of France, in the department of the Orne; 10 miles S.W. of Argentan.

RANESTAD, a town of Sweden, in Vangermanland; 50 miles N.E. of Hernoftand.

RANFORCEE RING. See Reinforced Ring.

RANG, in Geography, a town of Sweden, in the province of Vokien; 11 miles S.S.W. of Lund.

RANGA, in Hindoo Mythology, one of the many names of Siva, the personification, according to the Hindoo mythologists, of the destructive or changing form of the deity. (See Siva.) The epithet Sris, meaning holy, or divine, or bleffed, prefixed, has given this name to the capital of Mysore; Sris Ranga-pattan being the city of the bleffed Ranga, altered by Europeans to Seringapatam. See Sris.

RANGALORE, in Geography, a town and fortresses of Hindooftan, in the cercar of Cicecaco; 38 miles W. of Cicecaco.

RANGAMATTY, a cercar of Bengal, bounded on the N. by Boota and Affam, on the E. and S. by Affam, and on the W. by Baharund, Bettreund, and Gooolah; about 40 miles long, and from 10 to 40 broad. Rangamatty, the capital, is 128 miles N.E. of Moorheadabad, and has a celebrated pagoda. N. lat. 25° 8'. E. long. 90° 6'.

RANGANJA, a town of Bengal; 15 miles N.E. of Chittagong.

RANGAPALEAM, a town of Hindooftan, in Combetore; eight miles N.E. of Darapormum.

RANGAPILLA, a town of Hindooftan, in the Carnatic; six miles N.E. of Pondicherry.

RANGASUNDURAM, a town of Hindooftan; 15 miles W. of Timevelly.

RANGE, in Gunenery, the path of the ball, or the line it describes from the mouth of the piece to the point where it lodges. The flight of a shot is distinguished, by artillerymen, into three different ranges, of which the first is called the point-blank, the second the random-shot, and the third the ricochet, or rolling and bounding shot. The first, or point-blank, is to suppose a piece fired upon a level plain, and laid level, then the distance between the piece and the point where the shot touches the ground first, is called the point- blank range of that piece; but as the same piece ranges more or less, according to a greater or less charge, the point-blank range is to be understood to be that, when the piece is loaded with that charge which is commonly used in action. This range is much less than the greatest range, or random-shot; but the piece cannot be levelled, as it is generally expressed, printed at an object intended to be battered, if that object is not within the distance of the point- blank range; for beyond that the shot is very uncertain, therefore rarely used in the fire-service, and on land only when the shot cannot fail of doing great execution in the place on which it falls.

In ricochet firing, the piece is only elevated from three to fix degrees, and loaded with a small charge, in order that the ball may be bounded, and roll along the inside of the parapet. The shot, thus discharged, goes rolling and bounding, killing and maiming, or destroying all it meets in its course, and creates much more disorder by going thus slowly, than if thrown from the piece with greater violence. See Cannon, Gun, and Projectile.

Range of a Projectile, Amplitude of the. See Amplitude.

Range, Point-blank. See Point-blank.

Range, in a Ship, denotes a sufficient length of the cable, drawn up on the deck, before the anchor is cast loose from the bow, to let it link to the bottom, without being interrupted, that the flakes may be forced the deeper into the ground, by the additional weight which the anchor acquires in linking. For this reason, the range, which is drawn up out of the tire, ought to be equal in length to the depth of the water, where the ship anchors.

RANGER, a sworn officer of the forest, whose business it is to walk daily through his charge, to drive back the deer out of the purlicus or defafforeted places into the forest lands; and to prevent all trefpflers done in his bailiwick at the next court held for the forest.

The ranger is made by the king's letters, and has a fee paid yearly out of the exchequer, and certain fee-deer. In the Charte de Forela mention is made of twelve kinds of rangers. It is now principally a honorary and finecore employment; but the holders sometimes likewise receive pay.

Ranges, in Ship Building, horned pieces of oak, like baying cleats, but much larger, bolted to the midle of a ship, in the wall, for baying the tacks and flitches. Also those pieces of plank fixed between the ports, with semi- circular holes in them for keeping flot in.

Rangifer, in Zoology, a variety of the Cervus Tarandus; which fea.

Ranging, in War, the disposing of troops in a condition proper for execution, or for marching.

In Building, the tide of a work that runs straight, without breaking into angles, is said to range, or run range.

Rangina ou a canal, denotes determining or letting out on the ground the lines which are to be occupied by its middle and sides.

Rangie, in Falconry, is when gravel is given a hawk to bring her to her flomach.

Rangoon, in Geography, a sea-port town of the 3rd 2 2

Birman.
RANGOON.

Birman empire, situated on a branch of the Irrawaddy, called the Rangoon river, which forms the only communication that the Pegue river has with the sea. The town, in its present state, has been extended by increasing trade and consequent population far beyond the limits which formerly comprehended Rangoon, as it was originally founded, in 1755, by Alompra, the sovereign of the Birman empire. Rangoon, or Daogoung, which signifies victory achieved, was denominated Dagon, before Alompra took it, and laid the foundation of the present town. Here flood, in former days, a large and populous city, called in the Pali, or sacred language, Singourenta; the site of which Alompra diligently explored, and raised on its ruins the present flour-ishing sea-port of the Pegue dominions. Dagon, often called Sho-Dagon, or the golden Dagon, is a name peculiar to the temple; a noble edifice, three miles distant from the banks of the river. (See Daogoung.) Rangoon stretches along the bank of the river about a mile, and is not more than a third of a mile in breadth. The city, or moh, (mous being a term applied either to a city or a distri-ct,) is a square surrounded by a high stockade, in the manner of the country, and on the N. side it is further strengthened by an indifferent fosse, across which a wooden bridge is thrown; in this face there are two gates, in each of the others only one. Wooden flages are erected in fev-er al places within the stockade, for musqueteers to stand upon in case of an attack. On the S. side, towards the river, which is about 20 or 30 yards from the palisade, there are several huts, and three wharfs, with cranes for landing goods. A battery, of twelve cannon, six and nine-pounders, raised on the bank, commands the river; but the guns and carriages are in such a wretched condition, that they could do little execution. Close to the principal wharf are two commodious wooden houses, used by the merchants as an ex-change, where they usually meet in the cool of the morning and evening, to converse, and transact busines. The streets of the town are narrow, and much inferior to those of Pegue, but clean and well paved; there are numerous chan-nels to carry off the rain, over which strong planks are laid, to prevent an interruption of intercourse. The improve-ment of the town has been very much owing to the activity of the descendant of a Portuguese family, named Joumee, of low origin, but advanced at length to the important office of Shawbunder, or intendant of the port, and re-ceiver of the port-coumons. Under his direction and in-fluence, the streets were paved, several well built wooden bridges were constructed, and also a wharf, which, extending into the river, and raised on posts, enables the ships to de-liver and receive cargoes without the assistance of river-craft; under his direction also a spacious culum-house has been erected. This is the only lay building in Rangoon that is not constructed of wood, it is composed of brick and mortar, and the roof covered with tiles; within, there is a number of wooden flages for the reception of bale goods. The houses, in general, are raised on posts from the ground; the smaller supported by bamboo, the larger by strong tim-bers. All the officers of the government, the chief opulent merchants, and persons of consideration, live within the fort; shipwrights, and people of inferior rank, inhabit the suburbs; and one entire street, called Tackally, is exclu-sively allotted to common prostitutes, who are not permitted to dwell within the precincts of the fortification. Swine are suffered to roam about the town at large; they do not belong to any particular owners, but are regarded as fer-vants of the public, or common scavengers; as they go under the houses and destroy the filth. The Birman are also fond of dogs, numbers of which infest the streets; the breed is small, and very noisy. The borders of the terrace on which the temple of Dagoun is raised, are planted with shady trees in regular rows; and from this eminence there is a beautiful and extensive prospect; the Pegue and Rangoon rivers are seen winding through a level woody country, and the temple of Syriam, little inferior to others at Pegue and Rangoon, stands near the junction of the streams. The road leading from the city to the temple is formed with care, a wide caufeway in the centre throwing off the rain to the sides; and numberless little spaces are ranged along the edge of the road, in which are niches to receive small images of their divinity Guundia. Several kiosoms or monuailles lie in this direction, generally removed at a short distance from the public way, under the shade of pipal or tamarind trees. The Birman being, like other inhabitants of the call, fond of processions, scarcely a week passes in which there is not a religious display at Rangoon; either a funeral of flame perfon who leaves sufficient to defray the expense of a pompous public burning, or the ceremony of admitting young men to the convents of the Rahaans, on which occasion parents and friends spare no expence in entertainments and pre-ents to the Rahaans. See Rahaans.

The population of Rangoon is considerable; there are 5000 registered taxable houses in the city and suburbs; so that if each house be supposed to contain fix people, the effimate will amount to 30,000. Having long been the asylum of insolvent debtors from the different settlements of India, it is crowded with foreigners of desperate fortunes, who find from the Birman a friendly reception, and gene rally support themselves by carrying on a small trade. The exchange, if it may be so called, exhibits a motley affem-blage of merchants, such as few towns of much greater magnitude can produce; Malabars, Moguls, Perfians, Par fes, Armenians, Portuguese, French, and English. The members of this discordant multitude, engaged in various branches of commerce, are not only permitted to reside under the protection of government, but likewise enjoy the most liberal toleration in matters of religion. They cele brate their severall rites and festivals, totally disregarded by the Birman, who have no inclination to make profelyter. In the same street may be heard the solemn voice of the Muezin, calling pious ftable to early prayers, and the bell of the Portuguese chapel tinkling a summons to Romish Chriftians. Processions meet and pass each other without giving or receiving cause of offence. The Birman never trouble themselves about the religious opinions of any sect, nor disturb their ritual ceremonies, provided they do not break the peace, or meddle with their own divinity Guundia; but if any perfon commit an outrage, which the Mufulimen, in their zeal for the true faith will sometimes do, the offender is sure to be put into the flocks; and if that does not calm his turbulent enthufiam, he is ballinaded into tranquillity.

The Parfes, the Armenians, and a small proportion of Mufulimen, engrofs the largest share of the trade of Rangoon; and individuals from their number were frequently selected by government to occupy employments of trust, that related to trade and transactions with foreigners, the duties of which the Birman conceive that such perufons could perform better than themselves. These people, particularly the Armenians, naturally behoud with a jealous eye any ordinance of a commercial nature, that may tend to diminish their influence, and deprive them of that dictatorial power, which they assume and exercise over all merchants and mariners that refort to Rangoon; but of none are they so apprehensive as the English: a connection with whom might teach the Birman to transact foreign busines without their aid, and give them a more adequate sense of their own interest.

The
The French have long maintained an agent at Rangoon, and are thoroughly acquainted with the advantages which the country of Pegue affords. The imports into Rangoon from the British settlements in the years 1794—5, amounted, according to Mr. Symes, to more than twelve lacks of rupees, about 135,000/. The wood for the construction of ships, for the formation of docks: vessels of any burden may be built. Nature, says Symes, has liberally done her part to render Rangoon the most flourishing sea-port of the eastern world. The entrance of the river, about twelve miles below Rangoon, and the banks on each side, bear a near resemblance to those of the Ganges; but the navigation is much more commodious. The channel is bold and deep, from fix and a half to eight fathoms, uninterrupted by sandbanks or inequality of soundings. At this point the breadth of the river is limited to be from three quarters to one mile. On the bank of the river, opposite to Rangoon, is a commodious town, called Mawlamyine, the residence of the governor of the province of Yoma. This government is entirely distinct from Rangoon, on the calm side. The city of Yoma, from which the province takes its name, is laid to be on the west side of the China Buckler river, and was formerly a place of considerable importance. The town of Mawlamyine is composed of one long street; at the end is a creek, which runs all the way to Ballen, and has twelve feet depth of water, at high tide; on the west side is a smaller creek, on the bank of which stands a village called Mima-Shunrua, or the village of prostitutes, being wholly inhabited by women of that description. Rangoon lies in N. lat. 16° 47', E. long. 96° 9'. Symes's Embassy to Ava, in 3 vols. See BURMA Empire.

RANGISO, a town of Sweden, in Hufingland; 15 miles W.N.W. of Soderhamn.

RANGUANA, a small island in the bay of Honduras, near the coast of Mexico. N. lat. 15° 25'. W. long. 88° 52'.

RANHADOS, a town of Portugal, in the province of Beira; 18 miles N.W. of Caffel Rodrigo.

RANINA, Artaria et Vena, in Anatomy, the artery and vein situated on the inferior surface of the tongue. See Artery and Vena.

RANINAL VESSELS, Bleeding from. See Remum LINGUE, Division of.

RANISH, in Geography, a small island near the W. coast of Scotland. N. lat. 57° 55'. W. long. 5° 5'.

RANK, a due order, or a place allotted a thing suitably to its nature, quality, or merit.

Kings are persons of the first rank on earth. In cavalcades, processions, &c. every person is to observe his rank.

RANK, in Military Disciplines, denotes a series, or row of soldiers, placed side by side; a number of which ranks form the depth of the quadrille or battalion, as a number of files does the width.

When infantry is drawn up three deep, the first rank is called the front rank; the second, the centre rank; and the third, the rear rank.

To close the ranks, is to bring the men nearer; to open it, is to set them farther apart. To double the ranks, is to throw two into the space of one, by which the files are thinned.

See DOUBLING.

RANK, in the Army and Navy, is used for the order of precedence; which fee.

In the army the officers in the life-guards are entitled to the rank of lieutenant-colonel, when they obtain or purchase a majority, provided they are of seven years standing. Their commissions in this case run major and lieutenant-colonel. But if an officer should not have completed either of those periods, he obtains the rank of major only until its completion. A lieutenant-colonel attains to the rank of full colonel if he has been seven years major, or twenty-one years in the British service. Cornets in the life-guards rank as sub-lieutens in their own corps, and as first lieutenants in the army. The English fuzileers enjoy the same privilege. Sub-lieutenants in the Welsh fuzileers, rank only as second lieutenants in the army. Marines do the same.

Officers of the regular forces command the officers of equal degree belonging to the other services. Officers of the militia, fencibles, yeomanry cavalry, and volunteer corps, rank together, according to the dates of their respective commissions. The regulations are subject to some exceptions, specified in the articles of war. Officers of the militia rank generally with the regular forces as junior of their respective commissions. An ensign in the guards ranks no higher than an ensign in the regulars. The chief of the engineer ranks as colonel; director, as lieutenant-colonel; sub-director, as major; engineer in ordinary, as captain; engineer extraordinary, as captain-lieutenant; sub-engineer, as lieutenant; practitioner-engineer, as ensign.

In the navy the admiral or commander-in-chief of his Majesty's fleet has the rank of a field-marshall; admirals, with the flags on the top-mast-head, rank with generals of horse and foot; vice-admirals, with lieutenant-generals; rear-admirals, as major-generals; commodores with broad pendants, as brigadier-generals; captains of post-ships, after three years from the date of their first commission, as colonels; other captains, commanding post-ships, as lieutenant-colonels; captains, not taking post, as majors; and lieutenants, as captains.

RANK, Breve, rank without pay, nominal distinction, which sometimes entitles the holder of it to command in mixed service. The brevet rank in the militia is confined to the colonels and adjutants of the several corps in that establishment. The former receive the brevet rank of colonels in the army with actual embodiment for service, and command all lieutenant-colonels in the line when they do duty together. Adjutants in the militia may have the brevet rank of captain, provided they have served five years as lieutenants in the militia, or in other forces on the British establishment. In the line, an adjutant who has the rank of captain, may command as such when there is no superior officer on the parade, or for duty. This is not the case in the militia. No adjutant, let his brevet rank of captain be ever so ancient, can command the youngest captain of a company. The same difference prevails with respect to the captain-lieutenancy; which is literally brevet rank. In the regulars, a captain-lieutenant, the infant he is promoted to a company, takes rank according to the date of his first commission, and, as we have observed, may be major by brevet; but no captain-lieutenant can ever avail himself of that seniority to the prejudice of a captain of a company in the militia; nor can an officer in the latter establishment take advantage of his standing, when he quits one regiment to serve in another, even in time of war, although he may have the requisite qualifications in both counties.

Brigade majors rank with captains, provided they have
that rank in the army, independent of their staff appointment. But aids-de-camp do not possess any rank in that capacity with regard to the army. The latter constitute a part of the general's family, and are paid out of his allowance; they are in fact the mere carriers of his orders in the field, and his domestic inmates at home, &c. The former belong to the brigade, and are a necessary part of its effective force. It has been judiciously ordained, that both the one and the other should be regular officers.

There is likewise a sort of brevet rank which exists in the several regiments belonging to the British service, and is confined to the rank and file, or corporals and private soldiers. Thus a lance-corporal is a corporal who does the duty of lance-corporal without the pay or emoluments of the latter; and a lance-corporal is a private soldier who does the duty of corporal. So that lance, which comes from lance-corporal, and ought therefore to be written lance-corporal, &c. is the abbreviation of that word, which signifies a private soldier, and is derived from the German, and when put before lance-corporal, points out, that a private soldier has the brevet rank of one of those situations. Captains of companies appoint or reduce lance-corporals or corporals, according to their judgment.

RANK, in respect of ships. See RATE.

RANK and FILE, denote men carrying the fire-lock and standing in the ranks. Thus corporals are included in the return which is made under that head.

RANKS and Files, are the horizontal and vertical lines of soldiers, when drawn up for service.

RANK KEEL, in Ships. See KEEL.

RANK MODUS, in Lists. See MODUS.

Rank is also a term provincially applied to signify any sort of crop of large growth, standing thick or close on the ground, as corn, peas, beans, &c. and even trees in woods. The term is often used to denote corn or grass crops, which are of such strong growths as to be laid down or lodged.

RANKAH, in Geography, a town of Bengal; 25 miles W.N.W. of Palamow.

RANKERAH, a town of Hindoostan, in Candia; 25 miles S. of Burhanpore.

RANKNESS in GHâbâ, in Rural Economy, a term signifying its strong pungent quality arising from the impurity of the rennet or steep, either in consequence of neglect of the vessels holding it, the want of salt, or the imperfect separation of the curdy matter from the whey, by fermentation and partial purification occur and produce this taint. See CHEESE and Dairying.

RANKPORE, in Geography, a town of Hindoostan, in Guzerat; 45 miles E. of Redinepor.

RANNÉE, a town of Hindoostan, in Orissa; 30 miles S.S.W. of Balacora.

RANNEL-BAUK, in Rural Economy, a word provincially used to signify the wooden bar or hank laid across the cottage chimney, for hanging the pot-hooks on, &c.

RANNIGUNGE, in Geography, a town of Bengal; 76 miles N.E. of Dacca.

RANNING, a town of the duchy of Wurzburg; five miles N. of Schweinfurt.

RANNISERAI, a town of Hindoostan, in Allahabad; 35 miles N.W. of Gajipour.

RANNUTSCH, a town of Thibet; 36 miles E. of Athen. N. lat. 30° 42'. E. long. 82° 15'.

RANNY, in Rural Economy, a provincial word, applied to the small field-moule.

RANNY Bedneor, in Geography, a town of Hindoostan, in the ciregar of Sanore; 20 miles W. of Bilnaur. N. lat. 15° 18'. E. long. 75° 37'.

RANNYCOTTA, a town of Thibet; 35 miles S. of Gangotri.

RANNYDEE, a town of Bengal; 11 miles S. of Cur- ruckeal.

RANNYGONG, a town of Hindoostan, in Dowlata-

bad; 15 miles S.S.W. of Amedinagur.

RANNYGUNGE, a town of Bengal; 35 miles N. of Dinegongpore.

RANNYPOOKRA, a town of Bengal; 30 miles W.N.W. of Rognonpore.

RANO, a small island in the N. part of the gulf of Bothin. N. lat. 65° 45'. E. long. 22° 52'.

RANRAN, a town of Cochinchina, and the capital of a province. N. lat. 12° 59'. E. long. 108° 56'.

RANSACKEN, a town of the duchy of Wurzburg; 3 miles S. of Wurzburg.

Ransom, a sum of money paid for the redemption of a person out of slavery, or for the liberty of a prisoner of war.

With regard to prisoners of war, it is allowed that there is no obligation of releasing those who are detained as such, till after satisfaction has been obtained. Whoever makes a just war has a right, if he thinks proper, to detain his prisoners till the end of the war; and then, in releasing them, he may justly require a ransom, either as a compensation at a peace, or, if the war continue, for diminishing his enemy's prisoners, at the same time that he strengthens him with the return of soldiers. Prisoners of war, among European nations, are exchanged or ransomed during the war; and this is generally stipulated in a previous cartel. If sovereigns at war have agreed on a cartel for the exchange or ransoming of prisoners, they are faithfully to observe it no less than every other convention; but if, as was formerly the general practice, the state leaves to every prisoner, at least during the war, the care of redeeming himself, such particular conventions offer many questions, of which some of the principal are the following. He who has acquired a lawful right of demanding a ransom from his prisoner, may transfer his right to a third person. This was practised in the last ages. But as the person taking a prisoner is obliged, for the sake of his reputation, to treat him with justice and humanity, he is not to transfer his right, in an unlimited manner, to one who might probably abuse it. When he has agreed with his prisoner, concerning the price of the ransom, he may transfer the right to whom he pleases. On the conclusion of an agreement made with a prisoner for the price of his ransom, it becomes a perfect contract, and cannot be rescinded from, under a pretence that the prisoner is discovered to be richer than was imagined; for there is no manner of necessity that he should be rated according to the wealth of a prisoner, because that is not the scale for measuring the right of detaining a prisoner of war. But it is natural to proportion the price of the ransom to the prisoner's rank and character; the liberty of an officer of distinction being of greater consequence than that of a private man, or inferior officer. If the prisoner has not only concealed, but disguised his rank, it is a forcible fraud, and gives a right for annulling the agreement. If a prisoner, having agreed on the price of his ransom, dies before payment, it has been queried whether this price be due, and whether the heirs are obliged to discharge it? Unquestionably, says Vattel, they are obliged to it, if the prisoner died in the possession of his liberty; for, from the moment of his release, in consideration of which he had promised a sum, this sum becomes due, and does not at all belong to his heirs; but if he had not
not obtained his liberty at the time of his death, it can be
no debt to him, or to his heirs, unless the agreement was
otherwise; and he is not reputed to have received his liberty,
till he is absolutely permitted to depart free; when neither
whoeprisoner he was, nor the sovereign, opposed his re-
lease and departure. If indeed he has only been permitted
to take journey for applying to his friends, or his miter
reign, in order to obtain the means of ransoming himself,
and he dies before he is poffeffed of his full liberty, before
his final discharge from his perele, nothing is due for his
ransom. If, after agreeing on the price, he is detained in
prison till the time of payment, and he dies before, the
debt is paid by his death, and does not affect his heirs; such
an agreement on the part of him, who detains his prisoner,
being no more than a promise of giving him his liberty for
a certain sum paid down. A promife of buying and felling
does not propofe the purchaser to pay the price of a thing,
if it happens to perifh before the bargain is concluded. But
if the contract of fale be perfect, the purchaser fhall pay the
price of the thing fold, though it fhould happen to perifh
before the delivery of it, provided there was no fault or delay
in the feller. For this reason, if the feller has abfolutely
concluded the agreement of the ransom, and from that time
owns himself a debtor for the fhipulated fum, remaining no
longer as a prisoner, but for the fecurity of the payment,
his intervening death does not extinguife the debt: the ran-
sum agreed on remains fll due. If the agreement fays,
that the ransom fhall be paid on a certain day, and the
prisoner happens to die before that day, then the heirs are
bound to discharge it; for the ransom was due, and the day
was affigned, only, as the term for payment. Upon the
fame principles, strictly speaking, it follows, that a prisoner,
released on condition of procuring the release or discharge
of another, fhould return to prifon, in cafe the latter hap-
pens to die before he could procure him his liberty. Such
an unfortunate cafe, however, is entitled to regard, and
equity feems to require that this prifoner fhould continue in
the enjoyment of liberty, provided he pays a juft equivalent;
it being now out of his power to purchase it precisely at the
price agreed on. If a prifoner fully fet at liberty, after
having promised, but not paid, his ransom, happen to be
taken a second time, it is evident that, without being ex-
empted from paying his firft ransom, if he is willing to be
fet at liberty, he must pay a second ransom. On the con-
trary, though the prifoner has agreed for the price of his
ransom, if before the execution of the compact, before he is
fet at liberty in virtue of it, he be reftaken by his party,
he owes nothing. It is here evidently fuppofed, that the
finifhing hand was not put to the compact, and that the
prifoner had not acknowledged himfelf debtor for the rate
of his ransom. He whose prifoner he was, had, as it were,
only made him a promife of felling, and he had promifed to
purchase; but the purchase and fale had not actually paffed
into effect; the property was not actually transferred. The
property belonging to a perfon does not pafs to him who
takes him prifoner, unlefs at the fame time he feizes on fuch
things. Of this there is no doubt, efpecially in our times
of moderation, when prifoners of war do not fall into flav-
ery. And even by the law of nature, the property of a
prifone's goods does not, without fome other reafon, pafs to
the master of a prifone. There is nothing in flavery of which
this can itfelf be the natural effect. If a man obtain a
power over the liberty of another, does it follow, that he has
likewise a right over his property? Therefore, if a prifoner,
has not flipped his prifoner, or the latter has found means
to conceal fomething from his fearch, what he has preferred
fhould belong to him, or he may employ it towards the
payment of his ransom. At prefent even prifoners are not
always flipped. The death of a prifoner puts a period to the
right of him who had taken him; therefore an hoftage,
given for the procuring of a prifoner's liberty, is to be re-
leufed the moment the prifoner expires; and if the hoftage
dies, the prifoner is not releufed by fuch death. The re-
verse of this is true, if one, instead of being an hoftage for
the other, had been flubfitution in his head. Vattel's Law
of Nations, b. iii. ch. 17.

Formerly it was a common practice to ransome British
ships, when captured by an enemy, by delivering to the
ememy the price what was called a ransom-bill, which secured to the
ager the price agreed upon, and operated as a bill of fale
of the ship and cargo to the original owners, and as a pro-
tecition to the ship against other cruizers of the enemy during
the remainder of the voyaige. A hoftage was delivered to
the ager, for securing to him the puncual payment of the
ransam-bill. This ransam-bill, independent of the
hoftage, was confidered as a contract of the law of nations,
and obligatory upon the owners, as well as upon the captan
and hoftage who figned it; and actions have been often
brought upon them in our courts of common law. And
where the ship or goods were injured, the amount of the
ransom was usually taken to be the measure of the demand
of the injured upon the underwriters, in refpect of the cap-
ture. But this practice of ransoming ships captured by the
ememy being found to operate more to the difadvantage than
for the benefit of this country, it was thought proper at
length to prohibit it altogether. And therefore by ftat.
22 Geo. III. c. 25. § 1. it is enacted, that it fhall not be
lawful for any of his majefly's fubjeds to ransom, or to enter
into any contract or agreement for ransoming, any ship or
vessel belonging to any of his majefly's fubjeds, or any
merchandizes or goods on board the fame, which fhall be
captured by the fubjeds of any flate at war with his maj-
efly, or by any person committing hostilities againft his
majefly's fubjeds. By § 2. all contracts and agreements
which fhall be entered into, and all bills, notes, and other
fcuritites, which fhall be given by any perfon perfons for
ransam of any fuch ship or vefsel, or of any merchandize or
goods on board the fame, fhall be absolutely void in law,
and of no effect whatever. And by § 3. a penalty of 500l.
is given to the informer, for every offence againft the aét.
This ftatute has put an end to all qeelions on the law of

In our Law Books, ransam is alfo used for a fun paid
for the pardoning of fome notorious crime.

Horn makes this difference between ransam and amercia-
ment, that ransam is the redemption of a corporal punifh-
ment due to any crime.

It is never utial to affefs a larger fine than a man is able
to pay, without touching the implements of his livelihood,
but to inflict corporal punishment, or a limited imprifon-
ment, instead of fuch fine as might amount to imprifonment
for life. And this is the reafon why fines in the king's
court are frequently denominated ransoms, because the pe-
nalty mufi otherwise fall upon a man's perfon, unlefs it be
redeemed or ransamed by a pecuniary fine (Merr. c. 5. § 3.
Lambe. Cirearch. 57.) according to an ancient maxim,
"qua non habet in crumena laet in corpore." Yet, when
any ftatute speaks both of fine and ransam, it is held, that
the ransam fhall be treble to the fine at leaft. Dyer. 232.

RANSTADT, in Geography, a town of Germany, in the
principality of Stolberg; 17 miles N.E. of Frankfort
on the Maine.

RANSTADT, or Mark Ranstad, a town of Saxony, in
RAN

the territory of Merseburg; 10 miles S.S.E. of Merseburg. N. lat. 51° 18'. E. long. 12° 47'.

RANT, in the Drama, an extravagant flight of passion, overhooting nature and probability.

Lee's tragedies abound with rants; yet the wilder of them, it is observed, have frequently met with applause on the stage.

Weaned infancies of rants, even in our severest poets. Such, e. g. is that in the beginning of Ben Jonson's Catiline, where the parriicide, in speaking to Rome, says, 'I'd plow up rocks, steep as the Alps in dust; and have the Tyrrhenian waters into clouds, but I would reach thy head!'

RANTAMPOUR, in Geography, a cirecar of Hindoostan, in the country of Agimere, bound on the N. by Jyenagur, on the E. by Agra, on the S. by Kottah, and on the W. by Outipour and Sirowy.―Alfo, a town and fortrefs, being the capital of the above named cirear; 86 miles, E. of Agimeire. N. lat. 28° 35'. E. long. 76° 58'.

RANTZAU, John, in Biography, a general in the Danish service, was born in 1492, and at the age of 13 he entered into the army. In 1515 he began to travel into foreign countries, visiting in succession England, Spain, Germany, Italy, Greece, Syria, Palestine, and other parts of the East. In 1517 he was knighted at Jerusalem; and upon his return to Denmark, was appointed to accompany duke Christian, afterwards Christian III., on his tour to Brandenburg, and other towns of Germany. When Frederic I. accepted the crown of Denmark, he was promoted to be a general in 1553, and entrusted with the command of the troops in Holstein. He became greatly distinguished in his military character, and on various diplomatic concerns, and died in 1555. As an author he is known by the following works: "A true and brief Account of the Wars carried on in 1559, by Frederic king of Denmark, and Adolphus duke of Holstein," &c. "Decriptio Cimbriae," printed in Weiphalen's Monumenta inedita, tom. i. Gen. Biog.

RANTZEN, in Geography, a county of Germany, in the duchy of Holstein, about ten miles long and six broad. It takes its name from a flat seven miles N. of Entyn.

RANTZENBACH, a town of the duchy of Stiria; 6 miles N.W. of Mueckau.

RANTZENBACH, a town of Austria; 6 miles S.S.W. of St. Polten.

RANVILLE, a town of France, in the department of the Calvados; 5 miles N.E. of Caen.

RANULA, dim. of ranu, a frog. This term is, in Surgery, applied to a swelling of the salivary ducts under the tongue. Whether the tumour is so named from a whimsical supposition that it bears a resemblance to a frog, or from its being fancied to oblige the patient to make a croaking noise, in attempting to articulate, is a point which surgical writers leave undetermined. The swelling is round, of a greyish colour like a hydroid, soft, compressible, insolent, and, in the early stage, almost transparent. At first, it is of about the same size as a nut, or cherry; but, by degrees, its volume becomes much more considerable. It is very frequently met with in young children: its occurrence in adults is more uncommon. It consists of a succedaneous dilatation of the excretory tube of the submaxillary, or eel of the sublingual gland, the orifice of which duct is by some canes or another flapped up, or obliterated; so that the confined saliva accumulates, becomes viscous, and ceases to flow in the usual manner. In proportion as the ranula increases, the incipient flat of it having been completely obliterated; the enlarged fuse rises up the tongue, and forces it backward; the consequence of which is, that mastication, deglutition, and respiration, are obstructed. The voice becomes indistinct, and hoarse; the motion of the tongue is restrained: this organ cannot be put out of the mouth. By degrees, the incisor and canine teeth of the lower jaw are loosen'd; the layer of mucus, composing the lower parties of the mouth, is depressed; and the swelling, having attained a considerable size, makes a very manifest prominence beneath the chin. In this advanced stage, that is to say, when the ranula has existed ten or twelve years, as practitioners occasionally fee infanices of, the appearance of the swelling is quite altered from what it originally was. The tumour is now hard, elastic, painful, ulcerated, and, as it were, farcomatous: it is as large as a turkey's egg, and not situated at the side of the frenum, but anteriorly under the tongue, to which it is closely adherent. The mouth emits a very fetid smell; and the breathing is so much obstructed, that the patient, through fear of suffocating, is obliged to lie with his mouth wide open, when he goes to sleep.

While a ranula is recent, the fluid which it contains is a viscid saliva, resembling the white of egg, and sometimes of rather a yellow colour. In time it is gradually changed, becoming turbid and puriform; and, in certain infanices, foul, fribule, greyish concretions, from the size of a pea to that of an almond, commonly called salivary calculi, are found in the kind of cyfht, which is produced by the dilatation of the salivary duct. These calculi essentially consist of a large proportion of the phosphate of lime, united with a mucilaginous substance; and concretions of the same kind frequently occur in the tonsils, and in the salivary glands themselves, as well as their excretory ducts. Forestius, lib. xiv. obf. 26. p. 112. Blegney, Nouvelles Découvertes, &c. tom. i. ann. 1679, p. 235. Mém. de l'Acad. de Chirurgie, tom. v. p. 464. Petit, Œuvres Pothumes, &c. tom. i. p. 188. Bladius, Opif. 14. p. 81.

A ranula, whether recent or inveterate, cannot be cured except by a surgical operation. The cutaneous indication, in the first of these flates, is to make an outlet for the fluid accumulated in the tumour, and to make an opening sufficiently capacious to let the saliva readily pass into the mouth. Merely making an incision into the swelling, or opening it with a trocar, or a fenn drawn through it, are liable to be ineffectual methods. The tumour does indeed subsife as soon as the aperture is made; but the edges of the wound grow together again, and the dilate recurs. There is an absolute necessity for first making an incision the whole length of the swelling, and then removing, with the aid of forceps and a pair of dissecting forceps, a portion of the edges of the recent wound. This flight lots of substanbe prevents the return of the complaint, and always infures a free passage for the saliva; an advantage of which there is no necessity in any other mode of proceeding. By this operation, ranula in children may be cured in the course of a few days, without the least occafion for the application of any dressings whatsoever. It has been propofed to dilate the contracted orifice of the salivary duct with a probe. (Mém. de l'Acad. de Chirurgie, tom. iii. p. 460.) But this orifice is difficult of detection, and the swelling cannot be in this manner easily emptied. M. Laffis seems to entertain doubts whether Warton's canal can ever be made to resume its original flat, after once being closed. Pathology Chirurg. tom. i. p. 405.

When a ranula has existed a long while, it is attended with considerable hardnefs, and is of large size, it is a tumour which requires to be completely extirpated. A transverse incision, parallel to the opening of the mouth, is to be made in it through its whole extent. The surgeon is then to cut out
out the upper portion of the swelling, situated in front of the frænum of the tongue, to which it is also adherent, and next the inferior portion, which sometimes extends into the interphase between the genio-hyoidæ and genio-gloftis muscles, with which it becomes conflounded. A pair of forceps, a hook, scissors, and a straight bistoury, are the instruments necessary for this operation. A degree of hemorrhage always ensues. The use of a detergent gargoyle, made of barley-water and honey of roes, will serve to finish the cure in a very moderate space of time.

In confirmation of the latter observation, Laffus adds the following case. A young man, aged 22, had a ranula, which had continued ever since he was born, and was equal in size to a turkey's egg. The incisor teeth of the lower jaw were loosened, and forced forward by the succedaneous increase of the swelling. A fenton had been balled quite through it, without any useful effect. The breath of the patient and his saliva were intolerably fetid. The tumour was closely adherent to the lower and anterior part of the tongue; and extending laterally, confounded itself with this organ, of which it impeded the motion. A straight, narrow bistoury was introduced into one of the openings at the side of the tumour, and carried completely across to the opposite aperture. Thus a transverse incision was made into the cavity of the diseafl. By means of the same instrument and a hook, the lateral portions of the swelling were removed. A profuse hemorrhage ensued, caused by the total division of the frænum, the raninal veins, and one of the raninal arteries. It was stopped by putting under the tongue a large quantity of dry lint, and by compreßing the dorium of the tongue several hours with the fingers, while the thumb was employed in compressing the parts behind the chin from below upwards. This double fort of preflure answered the purpose. No cautery was found necessary, and, by the use of detergent gargles, the patient was cured in about a fortnight.

When a ranula of long duration, situated at the side of the tongue, and of considerable size, forms a tumour, that makes its appearance outwardly towards the base of the jaw, Laffus seems to disapprove of making a free incision through the skin, for the purpose of extirpating that part of the swelling which cannot be removed through the mouth; a plan which, in one instance, practised by Marchetti. Obf. Med. Chirurg. obf. 31. p. 48. See Laffus's Pathologie Chirurgicale, tom. i. chap. 61.

RANULACEAE, in Anatomy. See RANINA.

RANUNCULACEE, in Botany, the 6th natural order in Jullieu's fystem, or the first of his 13th clasfs, for whose character fsee GERANIA. The RANUNCULACEE are defined as foliows.

*Calyx of many leaves, somefome wanting. Petals definite, mostly five. Stamens indefinite, except in MYOFURUS; their anthers incorporated with the filaments. Germsa indefinite, except in MYOFURUS, placed on a common receptacle, each of them furnished with a fyle, which is rarely wanting, and a fimple stigma. Capsules, or rarely berries, as many as the germs; in some infulates fingle-fed, and not burling; in others many-fed, splitting half way down, at their inner margin, into two valves, bearing the seeds at the edges. Corollin minute, lodged in a cavity at the upper part of the large hoary albinon. Stem generally herbaceous. Leaves alternate; rarely (in CLERATIS and ASTRAGUS) opposite; some of them half fheathing the stem; some compound, pinuate or finged; some, as is more frequently the cafe, fimple, and their moftly palfme or lobed, their fälles often pale at the base. See RANUNCULUS.*

Jullieu divides the order in quifion into four fections.

**Sect. 1. Capsules fingle-fed, not burling; berries in Hydrafis.**

This fection contains Ciren, Atrogens, Thalictrum, Hydrafis, Anemone, Hamadryas of Commerson, Adonis, Ranunculus, Ficaria, and Myoferus.

**Sect. 2. Capsules many-fed, splitting at the inner edge. Petals irregular.**

The calyx in this fection is often coloured, being what Linnæus terms corolla; that author considering the petals of Jullieu as nectaries. The genera are Trollius, Helleborus, Ficaria, Nigella, Geranium, Aquilegia, Delphinium, and Acroniun. Some species of Delphinium have but a single capsule.

**Sect. 3. Capsules many-fed, splitting at the inner edge. Petals regular.**

Caltha, Peonia, Zanthonbriaga, Cimicifuga.

**Sect. 4. Germen solitary, Berry of one cell, with many seeds, affixed to a fingle lateral receptacle.**

The only genera are Artefa and Podophyllum, and thee we feel disposed to remove to Jullieu's next order, PAPAVERACEE. See that article.

We cannot but remark that the petals, as Jullieu terms them, in Trollius and Helleborus are by no means definite, and that they greatly exceed the number five. Neither are they irregular in Trollius. As to the other genera of his 2d fection, the parts in question are fuch obvious nectaries, that they can have no other function to perform, except possiblfy in Aquilegia, where their limb partsakes of the nature of petals.

RANUNCULOIDES, a genus of Vaillant's, founded on the Ranunculus hericaceus and acquata of Linnæus, and named from its resemblance or affinity to RANUNCULUS; fee that article. No one has followed Vaillant in this infuance, nor is there any real mark of distinction for his supposed genus. Ranunculoides is, belides, the specific name of a rare Britifh Anemone, but ranunculina would have been better Latin; as in Helleborus ranunculus, Sm. Pfl. fce. 2. t. 57. Willd. Sp. Pl. v. 2. 1336. See HELLEBORUS.

RANUNCULUS, an ancient name, whose origin is as obvious as its fene is obfure. The word is, no doubt, derived from rana, and means a little frog. The Greeks call the fame plant θάλαπης, which is nearly fynonimous. Moft etymologys fuppose this name to allude to the native ftation of the plant, in boggy watery places, fuch as frogs frequent. But the original θάλαπης of Dioscorides is the beautiful Ranunculus aquatius of Linnæus, or Garden Ranunculus, which inhabits corn-fields, and does not grow in wet places; though indeed the other three species, described by that ancient writer, do; there are our lamangifus, macricatus, and aquatius. It seems poelfible that the divisions of the leaves in all thefe plants may have fuggelted the idea of a frog's foot, which fupposition is confirmed by the English name, Crowfoot. Ambrofius hints at a refem-
what coloured, deciduous leaves. Cor. Petals five, obtuse, polished; with small claws. Nectary a cavity in each petal, half above the claw. Stam. Filaments very numerous, half the length of the corolla; anthers firmly united, erect, oblong, obtuse, of two separate lobes. P.flt. Germania numerous, collected into a head; styles none; stigmas reflexed, very small. Peric. none. Receptacle bell-shaped with extremely minute filaments, to which the seeds are attached. Seeds numerous, naked, irregular, uncertain in figure, with a reflected point.

Oh! The essential mark of this genus confits, as Linnaeus remarks, in the nectary, the rest of the parts being uncertain; hence he takes occasion to point out the use of advertising to that organ, which before his time had been neglected, and which his opponents accuse him of sometimes making of too much importance. The great Jullien will not, in this obvious case, use the language, though he adopts, unacknowledged, the idea of Linnaeus; nor will he allow the annullate nectaries of some of his RANUNCULAC

2. R. repens. Creeping Spear-wort. Linn. Sp. Pl. 773. Fl. Lapp. ed. 2. 198. t. 3. f. 5. Lightf. 282; fig. in frontispiece to t. 1. Fl. Dan. t. 108.—Leaves linear-lanceolate. Stem creeping.—About the margins of alpine lakes, on a sandy soil; common in Scotland, flowering in June and July. We have always thought this a variety of the former, as mentioned in Fl. Brit.; but Willdenow contends for the contrary. He truly affirms that it differs in having a thread-shaped creeping stem; linear entire leaves, tapering down into their footstalks; flower-stalks solitary, erect, single-flowered; and much smaller flowers. Nevertheless, we have seen many intermediate varieties, and such a disposition in weak plants of the Flammula to take root at their joints, that we may incline to our original opinion, suggested first by Linnaeus himself in his Sp. Pl.

5. R. filiformis. Slender Creeping Crowfoot. Michaux Boreal-Amer. v. 1. 320. Pursh n. 4. Lamarck Dict. n. 4.—"Stem thread-shaped, creeping, jointed, almost naked. Leaves linear-awl-shaped, obtuse. Flowers axillary, solitary, stalked."—In inundated places, on the banks of the river St. Lawrence at Hudson's bay and Labrador; flowering in June and July. This is described as a very small, slender, smooth species, very much resembling R. repens, n. 2. We have seen no specimen.

7. R.

8. R. pyrenaicus. Pyrenean Crowfoot. Linn. Mant. 248. Wildl. n. 6. Jacq. Mifc. v. 1. 154. t. 18. f. 1. (R. pumilus, gramineus foliis; Bauh. Hist. v. 3. append. 850. R. n. 1180; Hall. Hist. v. 2. 77.) R. plantagenus; Allion. Pedem. n. 1445. v. 2. 48. t. 76. f. 1.—Leaves linear-lanceolate, many-ribbed, fleshy. Stem erect, with one or two flowers; woolly at the top. Fruit somewhat cylindrical. Seeds with recurved beaks. Native of the Pyrenees, as well as of the Alps of Switzerland, Dauphiny, and Carinthia. Linnaeus, for a long while, confounded this with the last, and many botanists have considered them as hardly to be distinguished, but by the colour of the flowers. The leaves of the present vary greatly in breadth, being sometimes quite narrow and linear; but in variety B they are elliptical, and an inch wide. They appear to be green, not glaucous. The upper part of the stem, quite smooth in R. graminus, is always hairy, and under the flower is densely woolly, in the present species. The petals are pure white. Fruit nearly cylindrical. Seeds with elongated, remarkably recurved, points. Few plants vary more in luxuriance.

A most remarkable variety, as Haller and Villars esteem it, is the R. lacera, Bellardi Append. ad Flo. Pedem. 27. t. 6, of which we have a specimen from the author himself. In this the stem is branched, bearing thirteen or fourteen flowers, but its chief singularities consist in the jaggd, and partly amphi palmate, leaves, which nevertheless bear all the marks of casual luxuriance. We have a specimen of Allioni’s plantagenus, our variety C, which, by a tooth or two in some of the leaves, evidences an approach towards this lacera; and we have another of the same with four flowers on one stem.

9. R. parnassifolius. Parnassia-leaved Crowfoot. Linn. Sp. Pl. 774. Wildl. n. 7. Ait. n. 6. Curt. Mag. t. 586. Wulf in Jacq. Coll. v. 1. 191. t. 9. f. 3, without leaves. (R. n. 1179; Hall. Hist. v. 2. 77.) Herb. Davall.)—Leaves many-ribbed; radical ones roundish-ovate, somewhat heart-shaped, on long stalks; stem-leaves ovato-lanceolate, pointed, fleshy.—Native of the Alps of Switzerland, Dauphiny and Carinthia, as well as of the Pyrenees, from all which countries we have received specimens. The plant is esteemed very rare, and Wulffen regrets that he lost the root and leaves of his only specimen; so that Mr. Curtis has rendered a valuable service to botanists by his excellent figure. This is a singularly elegant species, on account of its leaves, which resemble our Parnassia, as well as for its large and brilliant white flowers, with their rose-coloured calyx. Their flarks are woolly. Fruit ovate. Seeds obovate, obtuse, with short incurved beaks. The root is perennial, formed of coipious, very long, pale fibres, as if it grew in watery places, but Haller says it inhabits stony alpine situations, being quite common in his own territory of Aigle.

10. R. opiohilofolius. Serpent’s-tongue Crowfoot. Wildl. n. 8. (R. opiohilofolius; Villars Dauph. v. 3. 731. t. 49.)—Stem simple, erect, leafy. Lower leaves ovate, or heart-shaped, many-ribbed, on long stalks; upper linear-lanceolate, fleshy. —Found between Toulon and Hyeres in Provence, by M. Villars, who mentions having seen a drawing of the same plant, in the royal collection at Paris, marked R. lecitos palulis, opioophilus folio; Tourn. Cor. 20. The root is described by Villars as somewhat bulbous, or tuberous, with many whorls of fibres. Stem erect, a foot high. Leaves smooth, rather feathery. Flowers small, yellow, with thin petals. Seeds in a small round head. He conveys it somewhat allied to R. Flammula. The resemblance of the leaves, in his plate, to parnassifolius, seems to have induced Willdenow to range it here. We have seen no specimen.

11. R. amphicaricis. Plain-tailed Crowfoot. Linn. Sp. Pl. 774. Wildl. n. 9. Ait. n. 7. Curt. Mag. t. 266. (R. folio plantaginis; Ger. Em. 563.)—Leaves ovate, pointed, glaucous, clasping the many-flowered stem. Root fimbriated.—Native of the Alpines and Pyrenean mountains, but not, as far as we know, of the Swiss Alps, Haller having miltaken his n. 1179, which is parnassifolius, for this species. It is a hardy perennial in our gardens, not difficult of culture, yet not common, flowering in May. The berbage is glaucous. Stem erect, leafy, with two or fifteen inches high, branched above. Leaves generally more or less fringed with soft hairs. Calyx green, smooth, conclave, partly membranous and white at the edge. Petals of a pure and brilliant white. Anthers yellow, as in other species. We have never seen the ripe seeds.

12. R. heterophyllus. Various-leaved Slender Crowfoot. (R. bonariensis; Lamark Dict. n. 9.)—Leaves stalked, toothed, heart-shaped or ovato-lanceolate, with three central ribs. Stem erect. Flowers stalked, solitary, opposite to the leaves. Seeds obtuse, granulated.—Gathered by Commerson at Buenos Ayres, in marthy places. Root fibrous. Stem erect, a foot or more in height, slender, smooth, fimbriated, branched, leathery. Leaves alternate, on long stalks; the lower ones ovate, or heart-shaped; the upper lanceolate, or ovate; all obtuse, more or less crenate or toothed, about an inch long, smooth, furnished with three central ribs, and several lateral branching veins. Footstalks bordered at their base; the lowermost much the longest. Flowers very small, white, on solitary, leafy, simple, leafy stalks, an inch and a half long, opposite to the leaves. Fruit ovate. Seeds obtuse, or obovate, rough with minute points. The calyx is smooth and reflexed, often remaining till the seeds are ripe.

13. R. flageoliformis. Long-stalked Crowfoot. Leaves on long stalks, heart or kidney-shaped, wavy or crenate. Stem creeping, thread-shaped. Flowers stalked, solitary, opposite to the leaves. Petals ovate. Seeds obtuse, dotted. —Native of Chili and New Granada. We have specimens from Mutis and Cavanilles, but this species does not seem to be any where described. The stems are long, thread-shaped, much branched, prostrate, creeping or perhaps floating, sending out from each joint long fibrous radii, and one or more smooth, roundish, heart-shaped or kidney-shaped leaves, hardly an inch wide; their footstalks measuring from two to three inches. Flowers very small, white, solitary, opposite to the leaves, on slender stalks, rather shorter than those of the foliage. Stamens few. Fruit rather oblong. Seeds obovate, obtuse, compressed, minutely dotted. This Ranunculus is perhaps most nearly akin to our British bederaceus, hereafter described, though very certainly different, and as the species are at present arranged, they must remain...
at a distance. In habit and general resemblance they closely accord.

15. R. falcatifolius. Salt-marsh Crowfoot. "Pallas's Travels, small edition, v. 5. 1733." Willd. n. 11. (R. rhenanus; Jacq. Hort. Vind. v. 3. 19. t. 31. R. repens, flore in caulce singulary, foliis varie fecitis; Amm. Ruth. Sl. 1. t. 13. f. 2.) — Leaves ovate, somewhat heart-shaped; toothed at the extremity. Stem creeping, thread-shaped. Flower-flanks solitary, mostly single-flowered. Petals obovate. Fruit nearly globose. — Found by Gmelin, on the banks of the Neva; Aurniana; by Pallas in the salt plains of Siberia, beyond the lake Betac. The flowers are yellow, as big as our common Crowfoots, being more than ten times the size of the leaf. Their petals are about ten, obovate. The root sends out long runners, like a garden strawberry. Gmelin's specimen is much smaller than Jacquin's figure.

16. R. bullatus. Portugal Crowfoot. Linn. Sp. Pl. 777. Willd. n. 16. Ait. n. 5. (R. lactuaceus; Dod. Fempt. 429. R. austroamalis Cufi; Ger. Em. 954. R. lactuaceus Chufi; ib. 955.) — Leaves ovate, serrate. Flower-flanks radical, single-flowered, hairy. — Native of Portugal and the north of Africa. Crowfoot, in England before 1640, but now scarcely seen. It flowers in May and June, and has a perennial frous root, more like Gerarde's fig. 10 than 11. Leaves all radical, divided, ovate, ribbed and veiny, somewhat hairy, strongly and unequally serrate, about an inch or an inch and half long; sometimes, according to Clusius, bifurcated. Flowers yellow, on simple, hairy, upright, radical flanks, three or four inches long. Petals more than five, narrow-obovate. The old authors delineate two kinds, generally suppose to be varieties, but which may possibly be species. We have not seen either, except in a dried state.

17. R. Ficaria. Pilewort, or Lefler Celandine. Linn. Sp. Pl. 774. Willd. n. 12. Ait. n. 9. Fl. Brit. n. 4. Engl. Bot. t. 584. Curt. Lond. falc. 2. t. 39. Mart. Ruth. t. 21. Bulliard t. 43. (Chelidonium minus; Matth. Valgr. v. 1. 578. Fuchi. Hilt. 867. Ger. Em. 816.) — Leaves heart-shaped, angular, smooth, falcated. Petals numerous. — Native of the upper parts of Europe, in moor, shady, or by banks, flowering in the early spring. Dr. Sibthorp found it common in Greece; and there can be no doubt of its being, as all botanists have judged, polygonal in Cyprus, the Lefler Celandine, of Dioscorides. Root perennial, fibrous, with many fleshy, fear-shaped, annual knobs, whole appearance gave rise to the Latin, as well as English, name of this species, and to an idea that the plant might be serviceable in the piles, as those who believe, may consult Gerard for the mode of application. The flesa are leathery, and mostly single-flowered. Leaves smooth and shining. Flowers falcate; with three, sometimes five, leaves to the calyx; and eight, occasionally ten, elliptic-oblong, highly polished petals, which fade to white in bright sunshine.

18. R. frigida. Alpine Siberian Crowfoot. Willd. n. 13. — Radical leaves wedge-shaped, ovate, five-toothed at the extremity; some of the fleshy, palmate. — Native of the alps of Siberia. Wildenow says he received this by the name of gralla, meaning glacialis, with which it agrees in the size, and perhaps colour, of the flower, but is abundantly distinct in the leaves." Several Siberian unnamed species, in the Linnaean herbarium, answer exactly to Wildenow's description. The radical leaves are cellular, stalked, between half an inch and an inch in length, smooth; rounded and entire at the base; abrupt and variously cut into broad blunt teeth, we might almost say lobes, at the summit. Stem erect, usually single-flowered, with two or three, alternate, fleshy, more deeply lobed, or palmate, leaves. Calyx brown, hairy. Petals five, variously heart-shaped, apparently white. The flower is so like glacialis, that we cannot but suspect the difference of the leaves, however great, to be but casual. At any rate, they are sometimes so deeply cut, that this species might perhaps, without violence, have been placed in the following section, next to glacialis.

19. R. Thora. Kidney-leaved Crowfoot. Poison-root of the Swiss. Linn. Sp. Pl. 775. Willd. n. 14. Ait. n. 10. Jacq. Auctr. t. 442. Obs. falc. 25. t. 13. (Thora major et minor; Caner. Epit. 825. 826. Th. valdenis, et montis Baldi; Ger. Em. 966. Pfeudo acomium pardinianches; Matth. Valgr. v. 2. 430.) — Leaves kidney-shaped, abrupt, crenate, reticulated; the radical ones on long flanks. Stems with one or two flowers. Bracteae lanceolate. — Native of the alps of Switzerland, Auffrta, and Greece, as well as of mount Baldus, near Verona, flowering rather early in summer. It is said to have been formerly in the English gardens, but has never fallen under our observation. Root perennial, of thick, tapering, fleshy fibres or rather knobs. Stem smooth, fufficient, near a span high; terminating in one, rarely more, long-flaked golden flowers, about half an inch wide; its calyx-leaves lanceolate, coloured, smooth, like every other part of the plant. Leaves about two inches wide, and one long, rather coriaceous, strongly reticulated with veins, neatly crenate, terminating either abruptly, with a notch, or elongated into three acute, entire, triangular, central lobes; the uppermost, or floral, ones, lanceolate and entire; the radical ones only on long fleshy flanks. Fruit globular, of a few, large, tumbid, ovate seeds, with hooked points. The root of this plant is reported to be extremely acrid and poisonous, its juice having been used formerly, by the Swiss hunters of wild beasts, to envenom their darts, whose wound by that means becomes quickly fatal and incurable. Hence the name, from Τήπης, corruption, or υπόμενον. We can see no possible reason for distinguishing the greater and smaller kinds, even as permanent, or well-marked, varieties.

Section 2. Leaves divided and divided.

20. R. criticus. Critical Crowfoot. Linn. Sp. Pl. 775. Willd. n. 15. Ait. n. 11. (R. criticus latifolius; Chuf. Hilt. v. 1. 239. Ger. Em. 963.) — R. macrophyllus; Desfont. Atlant. v. 1. 437. Lamarck Dict. n. 19. — Radical leaves kidney-shaped, crenate, somewhat lobed; stem in three deep, lanceolate, entire segments. Stem many-flowered. — Native of Crete; cultivated in the Oxford garden in 1678, but perhaps now lost. The root is perennial, of many thick, tapering, fleshy fibres. Stem thick, moderately branched, eighteen inches, or more, in height, hairy as well as the root of the herbage. Radical leaves from two to four inches long, and more in breadth; kidney-shaped, reticulated with strong veins, light green, downy, unequally divided into about four; three-crested, or coarsely notched, shallow lobes; fleshy-leaves alternate, in three deep, oblong, obtuse, entire lobes; the base tapering or wedge-shaped. Flowers several, yellow, nearly as large as R. Linn. n. 3. Calyx reflexed, ovate, loosely hairy. Petals yellow; appears, by the account of M. Desfontaines, to differ merely in having the lower
lower leaves more deeply lobed than usual, and somewhat less hairy.

21. R. caffianus. Calabrian Crowfoot. Linn. Sp. Pl. 775. Willd. n. 16. Ait. n. 15. (R. aequifolius, folio rotundo, ad radicem praefolante; Loef. Pruff. 255. t. 72.)—Radical leaves roundish-heart-shaped, crenate, undivided; stem-leaves in several deep, lanceolate, toothed and jagged segments. Stem many-flowered. —Native of Prussia and Siberia, flowering in May. Met. Loddiges are said to have introduced it into England, in 1794. Though the character of this approaches the bulb, the two plants are very different. The radical leaves of the present, though heart-shaped, are almost orbicular, their two lobes meeting each other; their margin harshly crenate, but not at all divided; their surface minutely downy. Stem much branched; smooth below; downy above; bearing several fingered, veiny, smooth, fiddle leaves; the lower ones largest, many-lobed, and jagged; the upper with only three lanceolate, entire leaves. Flowers rather small, deep yellow. Calyx hairy towards the base. Fruit ovate. Seeds hairy, roundish, slightly compressed, each with a strongly revolute back.

22. R. auricula. Wood Crowfoot, or Goldlocks. Linn. Sp. Pl. 775. Willd. n. 17. Ait. n. 13. Pursh n. 9. Flor. Brit. n. 5. Eng. Bot. t. 624. Curt. Lond. falc. 2. t. 41. Flo. Dan. t. 665. Ger. Ed. 954. (R. prima species sylvetris; Fisch. Hilt. 156. Dalech. Hilt. v. 1. 1029.)—Radical leaves kidney-shaped, deeply three-lobed, crenate; stem-leaves divided to the base into linear segments. Stem many-flowered. Calyx coloured. —Native of woods and shady places, throughout Europe; also in Pennsylvania; flowering in April and May. Root fibrous, perennal. Herb of a pale pleasant green, and deftillate of the acrimony usual in this genus. Stems a foot high, erect, branched, scarcely downy, except near the top. Leaves generally a little downy; the radical ones on long stalks, deeply divided into three or five, wedge-shaped, crenate, or cut lobes; the rest in many linear, entire, or partially cut, spreading divisions. Flowers terminal, erect, solitary at the top of each branch, of a bright golden hue. Calyx pale yellow, hairy, scarcely at all reflexed. Nutlets a naked petal in each petal, not clove by any scale. In cold backward feasons the petals are sometimes wanting, or rather identified with the calyx, which is then dilated, and more coloured than usual.

23. R. abortivus. Small-flowered Virginian Crowfoot. Linn. Sp. Pl. 776. Willd. n. 18. Ait. n. 14. Pursh n. 6.—Radical leaves heart-shaped, undivided, crenate; lower stem-leaves pedate; upper in three deep linear segments. Calyx reflexed, coloured. Petals obtuse. —In wet places, by the sides of ponds and ditches, from New York to Carolina, flowering in July and August. Pursh. In ponds at Buenos Ayres. Commerson. This species appears to have been cultivated in Chelsea garden 100 years ago, but it has, long since, disappeared, nor has any author given a figure of the plant. Its habit is much like fcleratus, n. 26. Root perennial, of many long fibres. Herb smooth. Stem from six to eighteen inches high, branched, leafy. Radical leaves like those of a violet, not an inch long, crenate, smooth; their stalks two inches, or more, in length; lower stem-leaves ternate, their lateral leaflets deeply divided, all cut or crenate; uppermost leaves nearly sessile, in three deep, lanceolate, entire divisions. Flowers small; yellow, according to Pursh, but Commerson, in his MSS. calls them flesh-coloured; each hand on a simple foliate stalk, half an inch or an inch long, either from the forks of the branches, or at their summits. The calyx is reflexed, large, membranous and coloured. We find scarcely any certain traces of petals, but the plant may be variable in those parts, like ariocorous. Stamus few. German large, globose. —Linneas took his specific character, aucta fabriniflora, from specimens not fully grown; yet he had an authentic one by him, with above thirty flowers. In Commerson's the upper leaves are more flaked than usual.

25. R. trilobus. Three-lobed Barbary Crowfoot. Def. font. Atlant. v. 1. 437. t. 113. Willd. n. 19. Stem erect, much branched. Leaves smooth, deeply three-lobed, cut, uppermost linear, obtuse, undivided. Flower-stalks frayed. Seeds compressed, tuberculated. —Gathered by Desfontaines, in moist fields, near Mayave, in Barbary. He describes it as skin to R. parviflorus, except in its upright growth, and smooth, deeply three-lobed leaves. The lowest leaf of all is undivided and crenate. Flowers very small, yellow, situated as in the two last. Seeds in a round head, small, compressed, orbicular with a point, covered with tubercles on both sides. To us this species seems, by its seeds, allied to parvifloris of Linneas, which is a variety of bisnus, hereafter described.

27. R. aequifolius. Aconite-leaved White Crowfoot. Linn. Sp. Pl. 776. Willd. n. 21. Ait. n. 16. Curt. Mag. t. 204. (R. inontanus quartus; also R. pleno flor: albo; Claf. Hilt. v. 1. 236. R. coniti folio; Ger. Ed. 954. R. albus multiflorus; ib. 957. R. albus, flore denfo; Bauh. Hilt. v. 3. 844, not 860.)—Leaves veiny, smooth, in five deep, pointed, toothed lobes; the middle one three-lobed; floral leaves fiddle, fingered, lanceolate, cut. Stem branched, many-flowered. —Native of the Alps of Switzerland, France, Austria, &c.; a hardy and long- ettablished perennial in our gardens, flowering in May and June; generally in a double flate, as figured by Curtis. He remarks that it requires moisture, shade, and a pure air. The stem is one and a half or two feet high, partly purpuril, smooth, with spreading branches. Leaves dark green, with a glaucous hue beneath; the radical ones on long stalks; the rest nearly sessile; all composed of more or less distinctly separate, often flaked, leaflets, strongly veined and coarsely toothed; the uppermost smaller, more timple, quite felfile. Flower:
Flowers white, three-quarters of an inch in diameter, not very ornamental in their single wild state, but much admired when double, and formerly called Fair Maids of France. Their pearly whitecaps is enhanced by the violet calyx.

Said to have been introduced into the English gardens in 1769, by Messrs. Kennedy and Lee. This is very distinct from the last, with which Linnaeus originally confounded it. The leaves are larger, not divided quite to the base, though their lobes are more cut and jagged; the floral leaves are remarkably long, slender, and entire. Flowers twice as large, and rather more abundant. The radical leaves of both have occasionally seven or nine lobes, instead of five.

29. R. fiscatus. Spike-fruited Crowfoot. Desfont. Atlant. v. i. 438. t. 115. Willd. n. 23.—Leaves radical, five-lobed, toothed. Stem nearly simple, hairy. Fruit cylindrical, thrice as long as the calyx.—Gathered by Desfontaines in marshes at Algiers. Root perennial, of numerous, oblong, flabby, tapering knobs. Stems solitary, erect, a foot high, hairy, simple, except at the top, where it divides into three or five simple fingered-flowered flasks; sometimes accompanied by a few bracteas, in three or four deep linear segments; sometimes naked. Leaves all radical, on hairy flasks, heart-shaped, rounded, five-lobed, strongly toothed, villous, about an inch and a half broad. Calyx of five ovate-oblong, coloured, hairy, spreading leaves. Petals five, obavoate, yellow, the size of R. acris. Fruit cylindrical, slender, an inch and a half or two inches long. Seeds very numerous, ovate, compressed, bordered each with a hooked, prominent beak.

30. R. paludosus. Marsh Crowfoot. Poiret Voy. en Barb. v. 2. 184. Lamarck n. 22. Desfont. Atlant. v. i. 439.—"Downy. Lower leaves in three deep, many-cleft, fan-shaped segments; upper simple, linear, entire. Stem branched, many-flowered. Calyx erect."—Gathered by Poiret, in the borders of extensive marshes, near la Calle, and in some other parts of Barbary. Root fibrous, densely faciculated. Herb downy, with short, close-furred hairs. Stems several, eight or ten inches high, with spreading leafy branches, bearing abundance of widely-spread, deep-yellow flowers, the size of the foregoing, on slender flasks of various lengths. Radical leaves flaked; the earliest ones ovate, undivided, deeply toothed; the rest almost pinnate, with three long, narrow, deeply cut, fan-shaped segments; those on the lower part of the stem less compound: the uppermost linear, undivided, acute, entire. Fruit oval, or almost elliptical, obtuse. Seeds oblong, smooth, compressed, scarcely pointed.

31. R. illyricus. Illyrian Silky Crowfoot. Linn. Sp. Pl. 776. Willd. n. 24. Ait. n. 18. Jacq. Audr. t. 222. Ger. Dod. Pempt. 428. Em. 953. (R. grumofa radice quartus; Cluf. Hibl. v. i. 240.)—Leaves flabby with silky hairs, linear-awl-shaped, ternate, entire. Calyx silky, reflexed. Stem branched. Flower-flasks woolly.—Native of Hungary, France, Italy, Austria, Thrace, and of the Swedish isle of Oeland; cultivated here in Gerard's time. Clusius received his specimens, from a physician of Ferrara, with the name of R. illyricus, which has been retained, absurdly enough, for a plant found in so many different countries, and for which so many expressive apppellations might easily have been contrived. The root is perennial, composed of numerous, small, round granulations. Whole herb more or less clothed with snow-white, silky, or partly cottony, down. Stem a foot high, or more, somewhat branched, bearing several bright lemon-coloured flowers, nearly the size of R. lingua, their calyx-leaves ovate, reflexed, externally silky. Leaves all linear-lanceolate, entire, feldon divided; the radical ones on long flanks, ternate or pinnate; those about the middle of the stem ternate, almost fiddle; upper ones simple; the usual length of each leaf or leaflet is two or three inches. —Dodonaxeus takes this for the second Briza, or Ranauculus, of Dioecides, with whose description it in some measure appertains. That species is said to be extremely acid. Hence Dodonaxeus, who is copied by Gerard, supposes our plant may be the Gelotosphyus of Pliny, which cauafed those who took it to dye laughing. But this opinion depends on too many conjectures to deserve attention; even if any benefit could be obtained from it. The former authors thus Dr. Sibthorp thought the above Ranauculus of Dioecides to be our Lanugina, which is a common Greek plant, and answers better to his description.

32. R. dulcis. Fan-leaved Crowfoot. Desfont. Atlant. v. i. 438. t. 114. Willd. n. 25. Pl. Grac. 313. (R. dulcis: t. 253.)—Leaves ovate, three-cleft, fimbriate. Column. Esqr. 312. t. 313. —Leaves undivided or divided twice ternate, toothed or deeply cut, fimbriated; upper ones ternate or simple. Stem hairy, simple, below, few-flowered. Fruit elliptical.—Found by Desfontaines, near Algiers, on moist uncultivated hills, flowering in winter: by Sibthorp on the northern mountains of Greece. Root perennial, of many oblong, tapering, clustered fibres, rather than knobs. Stem a foot high, hairy, somewhat divided above, and bearing two or three yellow flowers, the size of our common R. bulbifera, accompanied by deeply two or three-cleft bracteas. Leaves chiefly radical, on longish flanks; several of the earliest undivided, fan-shaped, strongly toothed; the rest deeply three-cleft, and subdvided.

33. R. aflaticus. Perisan Crowfoot, or common Garden Ranauculus. Linn. Sp. Pl. 777. Willd. n. 26. Ait. n. 19. Mill. Ic. t. 216. Sm. Fl. Grac. Sibth. t. 518, unpublished. (R. aflaticus, grumofa radice; Cluf. Hibl. v. i. 240—243. Ranauculus vari; Ger. Em. 955—960. Btr. 932; Dioec. book 2. chap. 266.)—Leaves once or twice ternate; leaflets three-cleft, cut. Stem hairy, branched. Petals three as long as the calyx. Fruit cylindrical.—Found by Dr. Sibthorp wild in various parts of Asia Minor, but most plentifully in the isle of Cyprus, where it still retains one of its ancient names, mentioned by Dioecides, orPhysicae, or Wild Parley. In the gardens of Europe it has been cultivated, ever since the latter part of the sixteenth century, under the form of innumerable varieties, chiefly double, of every variegated hue. In a wild and flage flate the large and splendid petals are of a most vivid crimson, occasionally varying to yellow. The root is perennial, of numerous, brown, flabby, tapering knobs. Stem twelve or fifteen inches high, erect, round, downy, hoary, leafy, branched from the middle or lower part, and bearing from three to five large long-flaked flowers, whose calyx is brown, hairy, and reflexed, but one-third the length of the broad, obavoate, concave petals. Leaves rather hairy, mostly flaked, variously three-cleft and notched, more or less compound; the floral ones, as usual, narrower and more simple. Fruit cylindrical. Seeds oblong, with recurved points.

34. R. japonicus. Japan Crowfoot or Ranauculus. Thunb. Tr. of Linn. Soc. v. 2. 337. Willd. n. 27. (R. aflaticus;
RANUNCULUS.

afaticus; Thunb. J. p. 244.—“Leaves deeply three-cleft, cut and toothed, hairy as well as the stem.”—Common in ditches about Nagasaki, Jedo, and elsewhere in Japan, flowering from February to May. It is hairy in every part, except the corolla. The radical leaves are rounded; the uppermost divided into lanceolate segments; all three-cleft, their segments cut, toothed, acute, hairy on both sides. Flower-stalks from an inch to a foot in length. Stems branched, distinctly hairy, zigzag, branching into flower-stalks at the top. Thunberg. The above character and description are not sufficient to distinguish this species from the last, with which Thunberg originally confounded it. Something is necessary to be known respecting the calyx, and its relative proportion to the petals, as well as the form of the fruit and seeds.

35. R. rufulifer. Ruful-leaved Crowfoot. Linn. Sp. Pl. 757. Wildd. n. 28. Ait. n. 22. Jacq. Coll. v. 1. 185. t. 6, 7. AllIon. Pedem. v. 2. 49. t. 67. f. 1. (R. preceus rutaceus folio; Chuf. Hilt. v. 2. 232. Ger. Em. 965. R. rufulifer. Linn. non Conf.)—Leaves pinnate, ternate, many-cleft, glaucous, smooth; their segments elliptic-oblong. Stems nearly simple. Petals numerous. Calyx smooth. Seeds ovate, with straight points.—Native of the highest alps of Switzerland, Dauphiny, Austria, and the north of Italy, flowering early in July. The root is tuberous, with long, fleshy, stout fibres, perennial. Herb glaucous and smooth. Stem from two to five inches high, mostly simple and fingle-flowered, sometimes bearing two, rarely three, flowers. Leaves tufted, elaborately compounded; their leaflets wedge-shaped, many-cleft; the ultimate segments oblong, lightly elliptical, blunter. Flowers of a brilliant white, at first tinged with red, on long stalks. Calyx purplish, five-leaved, smooth. Petals eight or ten, very erroneously represented in the figure of Clusius and Gerardus, so as to look like a fingle-leaved flower. Seeds few, large, ovate, pitted, pointed, straight, spreading every way, falked, in a round head.

36. R. glacialis. Alpine Hairy-cupped Crowfoot. Linn. Sp. Pl. 757. Fl. Lapp. ed. 2. 195. t. 3. f. 2. Wildd. n. 29. Ait. n. 21. Fl. Dan. t. 19. (R. montanus purpureum, calyce villoso, Fiecalis Tienter; Bohl. Hilt. v. 2. 846. Scheuchz. Alp. v. 1. 399. and 129. t. 20. f. 1.)—Leaves ternate, three-cleft, cut; their segments elliptical. Stem nearly simple. Calyx very hairy. Native of the highest alps of Lapland, Switzerland, Dauphiny, Germany, &c. in the neighbourhood or ice and snow, flowering in June and July. Root perennial, with very long strong fibres. Stem from two to three inches high; fimple and nacked in its lower part; leafy near the top, bearing one or two, very rarely three, flowers, on long, smooth stalks. Leaves green, scarcely hairy, rather flessy; the radical ones more or less compound, on long stalks; their segments broader, more elliptical, and blunter than in the former. Flowers large and handsome, of five broad, roundish, white petals, rose-coloured or purple underneath; the calyx purplish-brown, sinuately rough, with shining tawny hairs. When we contemplate the great diversity of subdivision in the foliage of this species, we are disposed to believe our Frigidus, n. 18, may possibly be a mere variety. Their flowers precisely agree, as well as their general habit.

37. R. Seguieri. Sharp-leaved Alpine Crowfoot. Villars. Dauph. v. 3. 737. t. 49. Wildd. n. 30. (R. Columnus; Allion. Pedem. v. 2. 50. t. 67. f. 3, 4. Wulf. in Jacq. Coll. v. 4. 345. R. alpinus epilo folio, flore albo magnio; Pont. Comp. 117. Seguieri Veron. v. 1. 490. t. 12. f. 2, 3.)—Leaves ternate; segments wedge-shaped, subdivided, dentate, acute. Stem branched, about three-flowered. Calyx smooth.—Native of Mount Baldus, where it was first found by Pontedera; as well as of the mountains of Dauphiny, Piedmont, and Carniola; in flomy situations. This resembles some of the most luxuriant varieties of glacialis, but differs in the acute and decurrent segments of its leaves, as well as in its smooth pale calyx; for Villars is incorrect in describing that part “externally down.” It is quite smooth, in his own and Allioni’s figures; the hairs being confined to the top of the flower-stalk, where it is very dense and conspicuous; while the same part in glacialis is smooth, up to the base of the hairy calyx. The petals, and even the pedicel, are white. Villars is surely right in removing the synonym of Columna, cited by Allioni, which we refer, with hardly any scruple, to Frigidus, n. 32, a very different plant.

38. R. vialis. Palmate Alpine Crowfoot. Linn. Sp. Pl. 778. (Excluding the variety.)—Leaves palmate, five-cleft, spreading, entire; those of the stem fimple. Stems single-flowered, smooth. Calyx hairy, half the length of the petals.—Found by Linnaeus in Lapland, by the alpine rutilus on the snowy mountains of that country. Martens had previously gathered it at Spitzbergen. The root is fibrous, and slender. Stems single, erect or ascending, smooth, leafy, about six inches high. Radical leaves two or three, on long fider stalks, heart-shaped at the base, rather deeply palmate, in five broad, divaricated, obvate, entire lobes, very and quite smooth: Petals one or two, fefile, with five deeper, longer, more lanceolate lobes; the uppermost only three-cleft, or occasionally quite undivided. Flower solitary, on a long, terminal, hairy stalk. Calyx of five ovate yellowish leaves, rough with blackish hairs. Petals yellow, obvate, twice the length of the calyx.

39. R. pygmaeus. Dwarf Small-flowered Alpine Crowfoot. Pursh n. 10. (R. vialis pygmaeus; Linn. Fl. Lapp. ed. 2. 176. t. 3. f. 3. R. lapponicus; Fl. Dan. t. 14.)—Leaves palmate, somewhat pedate, five-cleft, spreading entire; the upper ones almost fefile. Stem single-flowered. Calyx nearly smooth, rather longer than the petals.—Native of Lapland and Labrador. Perennial, flowering in May and June. Much smaller than the foregoing. Middle lobe of the radical leaves very deeply separated. Petals less perfectly fefile, and with narrower segments, than in vialis. Flower not a quarter the size of that species; its petals yellow, roundish, scarcely so long as the calyx, which is likewise small, and very flightly hairy.

40. R. montanus. Yellow Mountain Crowfoot. Wildd. n. 32. Ait. n. 22. (R. vialis; Jacq. Aufr. t. 325. 326. Sibth. in Prodr. Fl. Grac. n. 1727 ? Villars Dauph. v. 3. 742. Crantz Aufr. f. 2. 92. t. 4. f. 3, 4. R. vialis; Hall. Hilt. v. 2. 71, excluding the references to Linnaeus. R. minimus alpinus lutesc; Bohl. Hilt. v. 2. 845, two upper figures.)—Leaves five-cleft, rounded, cut; those of the stem fefile, with deep, lanceolate, entire segments. Stem single-flowered, rough with ecref hairs. Calyx hairy. Very abundant on the alps of Switzerland, Dauphiny, and Germany; not of Lapland. It was one of those many alpine plants, introduced into the English gardens in 1775, by a person set on purpose to collect them, at the expense of Dr. Fothergill and Dr. Pitcairn. This species has been confused with the Linnaean vialis, by all writers previous to Willdenow; yet they are truly distinct. The montanus has remarkably long, subdivided, tuberous roots, with very long strong fibres. Stem hairy throughout, the hairs ecref; sometimes quite leaflets. Lobes of the radical leaves unequal.
equally cut and toothed, not entire. *Calyx-leaves* narrower, and leafs hairy. *Petals* larger, and of a deeper yellow. This is the *nivialis* of most botanists, few having seen the true Linnaean Lapland plant. The variety of montanus with a leafless *stem*, figured in Jacquin's t. 326, at the right hand, was taken for a new species, and called *alpina*, by Fawrod and Revnner, as appears by their dried specimens.

41. *R. Gouani.* Gouani's Pyrenean Crowfoot. Wild. n. 33. (R. pyrenaicus; Gouani Illust. t. 17. f. 1, 2.)—Leaves five-lobed, rounded, cut; those of the *stem* edified, deeply palinite; the uppermost with acute, entire lobes. Stem single-flowered, rough with defixed hairs. Calyx hairy.—Gathered by Gouani on the Pyrenees, where it flowers soon after the melting of the snow. We have a specimen from the late M. Bauflonnet. This is a larger plant than the preceding, especially in its *flowers*, and differs, as Willdenow remarks, in having the *stem* leaf toothed or cut; but that character applies only to the lower one. The upper *stem-leaves*, if there be more than one, confer of entire, acute lobes. The most decisive mark of distinction appears to us in the hairs of the *stem*, below the leaves, which in Gouani's plant are either widely extended or bent downwards; in the *montanus* the hairs of every part of the *stem* are edified, or close-preled. To this no peron has hitherto adverted.

42. *R. alpestris.* Alpine White Crowfoot. Linn. Sp. Pl. 778. Wild. n. 34. Ait. n. 23. Sm. Tr. of Linn. Soc. v. 1804. 343. Eng. Bot. t. 1390. Jacq. Nativ. t. 110. (R. n. 1167; Hall. Illust. v. 2. 71. R. montani species prima et secunda; Chur. Illust. v. 1. 234. R. montanus, flore minoro, & majore; Ger. Em. 964. R. minimum alpinus album; Buhl. Illust. v. 3. 845; two lower 7.)—Leaves very smooth; radical ones somewhat heart-shaped, obtuse, in three deep, lobed segments; *stem* leaf lanceolate, entire. Stem softly single-flowered. —Native of the highest alps of Austria and Switzerland, and of the mountain of Cloua, in Anguished, Scotland, in which last place it was discovered by the late Mr. George Don, by the sides of little rills, flowering, though sparingly, in the spring of 1800. The roots are perennials, with long fibres. Whole herb very smooth, and rather glaucous. Stem erect, from one to four inches high, almost always simple and single-flowered, naked, except one or two simple, linear-lanceolate, obtuse, entire leaves, apparently of the nature of bracteas. Radical leaves several, glabrous, in three deep, divided, acute lobes. *Calyx-leaves* ovate, smooth, edged with white. *Petals* of a pure and brilliant white. Haller says this is one of the most acute of its tribe, blustering the skin; and yet the alpine hunters chew it, by way of refreshment.

43. *R. lapponicus.* Long-stalked Lapland Crowfoot. Linn. Sp. Pl. 778. Fl. L. ed. 2. 1804. 3. f. 8. Lap-land Tour, v. 1. 156, 252.—Leaves smooth, in three very deep, dilated, blunt notched lobes. *Flowery-flarks* elongated, naked, single-flowered. Petals the length of the smooth calyx. —This rare species, not known out of the limits of Lapland, was discovered by Linnaeus in two or three different places, near the river Juchan, flowering in June. Professor Swartz also gathered it, many years after, near Luka. It grows in watery situations, and is very different from all others of this genus. The aspect of the plant, at first sight, recalls the idea of *Adonis Maschigallina*. The root is long, thread-shaped, and creeping, throwing up here and there, from its joints, a little, short, simple, solitary, smooth *stem*. petals, sometimes an inch or two high, sometimes scarcely distinguishable. *Leaves* one on the base, and another from the top, of the *stem*, on *flanks*, two or three inches in length; *each leaf* an inch or

an inch and half wide, smooth, veiny, rather fleshy, something kidney-shaped, in three very deep, almost distinct, broad wedge-shaped lobes, having a few broad and rounded, blunt notches, each tipped with a minute glandular point. *Flower-flarks* from three to five or six inches high, terminating the stem, solitary, simple, naked, smooth, each bearing a small yellow *flower*, scarcely half an inch in diameter. *Calyx* of three elliptical, concave, smooth, pale, reflexed leaves. *Petals* five or six, obvate, ribbed, about the length of the calyx; their sepal cut by a scale. *Stamens* from nine to twelve. Petals from fix to twelve. Petals in a round head, ovate, smooth, with strongly recurved points.

44. *R. hyparauicus.* Arctic Crowfoot. Retz. Scand. ed. 1. t. 11. "Wild. n. 36. "Rotth. in Copenh. Transf. v. 10. 1589. t. 4. f. 16." (R. Fl. Dan. t. 331, excluding the synonym of Amann, which belongs to *flosculiflorus*, n. 15. R. n. 50; Gmel. Sib. v. 4. 204. t. 83, b, excluding the Linnaean synonyms.)—Leaves smooth, in three deep divided lobes; the lateral ones clavate. Stem creeping, Flower-flarks the lengths of the leaves. Petals scarcely longer than the smooth calyx. —Native of Iceland, Greenland, Norway, and Siberia, in watery places. Gmelin and Linnaeus confounded this with *hederacea* hereafter mentioned; Gunner mistook it for *flosculiflorus*, which he called *R. Amannii*, Fl. Norv. n. 826. From both, as well as from *lapponicus*, it is very distinct. The *flanks* are long and creeping, or floating, throwing out from each joint, several simple, very long, fibrous radicles, with a falked leaf, not a quarter the size of *lapponicus*, whose leaves are by no means toothed or crenate, the lateral ones only being simply clavate. The *flowers* are small, pale yellow, solitary, each on a lateral, but not axillary, *flalk*, whose length is about equal to the adjoining leaf with its *foot-flalk*. *Calyx-leaves* only three or four, smooth, coloured. *Petals* about the same name, and scarcely longer, obvate. *Seeds* ovate, gibbous, with a hooked, but very short, beak.

45. *R. monticellus.* Montpellier Crowfoot. Linn. Sp. Pl. 778. Wild. n. 37. (R. saxatilis, magno flore; Buhl. Prodr. 96. Sauv. Monpl. 818.)—"Leaves in three deep crenate segments. Stem simple, villous, nearly naked, single-flowered."—Native of rocky places about Montpellier, according to Bauhin, who thus describes his plant. "Root composed of long capillary fibres. *Leaves* from the root several; on long, somewhat woolly, *flalks*, each leaf hardly so broad as the nall, in three small segments, which are again divided into two or three acute ones. The *flalk* is about three inches high, slender, woolly, bearing one large *flower*, of a brilliant golden yellow, composed of five petals, with many reddish *flaments*." We know no authentic specimen nor figure of this plant. Linnaeus has marked it as never seen by him; but a specimen sent him by Gouan, from the Pyrenees, marked *R. alpinus humilis, magno flore*, which we have been directed therefore to consider as *R. Gouani*, n. 41, answers very well to Bauhin's description, and it is not impossible that these supposes two species are one and the same. Yet Poiret, who professes to have gathered *R. monticellus* at Montpellier, and in Barbary, speaks of them as distinct, though, it must be confessed, his description is hardly sufficient to establish the point in dispute.

RANUNCULUS.

Cylindrical. Seeds compressed, with straight beaks.—Native of low meadows, from Canada to Pennsylvania, but rare, flowering in July and August. This species was sent by Professor Thunberg, in 1785, to Kew garden, from whence we procured a specimen the same year. Mr. Aiton makes it biennial; Jacquin and Pursh perennial. The stem, like the footstalks, is very hairy. Whole herb of a light green, two feet or more in height, branched, many-flowered. Leaflets one and a half or two inches long, strongly veined, with spreading segments. Flower-flakes terminal, long, furrowed, rough with close-prehired hairs. Flowers small, their little, round, yellow petals not so long as the calyx, which is smooth and bent downward. Seeds in a cylindrical head, numerous, ovate, gibbous, compressed, smooth, very minutely dotted, each tipped with a short, sharp, erect, or slightly inflexed beak. 

47. R. ternatus. Ternate-leaved Japanese Crowfoot. Thunb. Jap. 241. Willd. n. 39. —"Calyx reflexed. Leaves all ternate; leaflets three-cleft. Stem many-flowered."—Native of the Japanese island of Nipon, flowering in May. Nothing more is known of this species, concerning whole peculiar characters, or affinities, we can form no precise opinion.

48. R. bisternatus. Twice-ternate Magellanic Crowfoot.—Leaves smooth, twice ternate, cut; segments ovate, acute. Stem creeping. Stalks single-flowered, the length of the leaves. Petals obovate, the length of the smooth calyx.—Gathered by Commerson, in the fronds of Magellan. No author appears to have taken up this species, of which a specimen, from Commerson's herbarium, was given by Thouin to the younger Linneaus. The whole plant is smooth. The leaves bear a considerable resemblance to those of R. Seguiier, but are rather smaller, and distinctly twice-ternate. The habit of the plant more accords with lapponicus and hyperboreus, however unlike at first sight. The stem is thread-shaped and creeping, fending forth, from every joint, a few fibrous radicles; a pair of upright, flaked leaves, two or three inches in height, and one flower, whose white, naked stalk is about as tall as the leaves. This flower appears to be extremely like that of lapponicus, though scarcely more than half so large. The dried petals have the same opaque whitelessness as is observable in that species, and others, on their upper surface, and are probably yellow when fresh.

49. R. pedunculatis. Long-stalked Magellanic Crowfoot. —Leaves ternate, deeply cut, somewhat hairy. Stems hairy, taller than the leaves, two-flowered. Calyx reflexed, nearly smooth. Seeds globose, smooth, with recurved, hooked beaks.—Gathered by Commerson in the fronds of Magellan, with the preceding. This has a general likeness to several common European kinds, which we shall next describe, but is essentially distinct. The radical leaves are several, on hairy stalks, four inches long, their circumscipion roundish, measuring an inch, or inch and half, across; the leaflets almost always quite distinct, with short partial stalks, their form wedge-like, or fan-shaped, more or less deeply cut, seldom regularly three-cleft. Stems several, erect, filiform, rough, with spreading hairs; simple and naked to the height of four or six inches, then dividing into two upright, hairy, simple flake-stalks, greatly elongated, (from one to seven or eight inches), after flowering, and accompanied at their base by a solitary, flaked, deeply divided, palmate or fingered, leaf, an inch long. The flowers are much like those of bulbosus, or acris. Calyx leaves ovate, concave, reflexed, bearing a few external hairs.

Petal yellow, wedge-shaped, filiform, nearly twice as long as the calyx. Fruit globose. Seeds globose, tumid, keeled, even and smooth; their beaks rather spreading, hooked at the tip.

50. R. bulbosus. Bulbos Crowfoot, or Butter-cups. Linn. Sp. Pl. 778. Willd. n. 40. Ait. n. 25. Fl. Brit. n. 7. Engl. Bot. t. 515. Pursh n. 12. Curt. Lond. falc. t. 38. Mart. Ruff. t. 28. Gen. Em. 933. Lob. l. 666. —Leaves hairy, ternate, three-cleft, cut. Stem many-flowered. Calyx reflexed. Seeds compressed, smooth. Root bulbous. —Very common in Europe, as well as North America, in meadows and pastures, flowering throughout the summer. The root is a round, solid, perennial bulb, about an inch in diameter, increasing by offsets from the top, and sending out from its base many long stout fibres. Stems several, erect, a foot high, branched, leafy, round, hairy, many-flowered, deficate of trailing hoots or runners. Leaves flaked, variously cut, more or less hairy. Flowers terminal, solitary, on angular furrowed stalks, rough with erect, sharply hairy, Brithflakes. Calyx hairy, bent back to the flake. Petals nearly equal in size to R. Linguas, of a deep shining yellow. Nectary covered by a notched scale. Fruit globose. Seeds orbicular, greatly compressed, bordered, smooth, and even, tipped with a short blunt beak. This is one of the most acid, and even caudacious, species. Villars says the root may be used as a blitter, instead of cantharides, but not so fatally. It is most active in the spring, and must not then be left on the skin more than four or six hours, for fear of leaving a dangerous spreading sore.

Vol. XXIX.

3 H Lamarck)
Lamarck) describes them in his *R. agrarius*, cited above.—This species has been very little understood. It is remarkable that any botanist should confound it with *bulbus*, or with *federatus*, and that Mr. Curtis, in labouring to distinguish it, did not advert to the deceptive character of the tuberculated seeds, by which it approaches a very different tribe, hereafter described, consisting of *parviflorus*, *muricatus*, &c. Even Ehrhart has not noticed this circumstance.

We are obliged to Edward Forster, F.L.S. for tracing out the identity of *R. parvulus* and *bifurcatus*, and we cannot but prefer Curtis’s original name for the species, rather than Ehrhart’s pedantic one of later date. On the account of priority *federatus* perhaps ought to have been retained; but this name is founded on a very dubious opinion, that the plant of which we are speaking caused the Sardinian laugh. Valerius Cordus, indeed, says it grows copiously in Sardinia, and it has certainly the appearance of Smallage, *Aethion*, so far answering to the ancient history. But the account of Cordus seems taken from Dioscorides, whose "second Ranunculus" is more probably the Linnaean *laeinogina*, a still more general plant of the south of Europe than that of which we are speaking. After all, the famous Sardinian herb, compared to Smallage, may be actually wild Smallage or Celeria, *Aethion graminus*, which is sufficiently acid and poiseous to warrant our supposition, though it becomes sweet and wholesome by culture. In this uncertainty it is surely best to call our plant *R. bifurcatus*.

52. *R. polyglossa*. Oriental Marsh Crowfoot. Linn. MSS. (R. orientalis palustris, api folio, caule fimbriato; Tourn. Cor. 20.)—Leaves hairy, in three or five deep segments, bluntly notched, with rounded dilated sinuses. Stem erect, branched, almost leafless. Calyx spreading. Seeds ovate, compressed, very smooth, with a short recurved beak.—Native of the Levant. An oriental specimen, with Tournefort’s synonymy, is preferred in the Linnaean herbarium, and named *polyglossus*, but we cannot find mention of it elsewhere. This is certainly a most distinct species, though not taken up by any recent author. The root consists of many fleshy knobs, tapering into fibres, and resembling those of *R. aethiopicus*, though not so thick. Stem two feet or more in height; hairy below; much branched, and almost leafless above; the branches terminate. Leaves chiefly radical, on long hairy stalks; their outline somewhat pentagonal; heart-shaped at the base; hairy on both sides, about two inches wide; their three principal lobes spreading, deeply separated by wide rounded sinuses, and notched nearly at the extremity by broad, rounded, abrupt teeth; the upper or floral leaves are small, short, linear, undivided. Flowers, as far as we can judge, yellow, not large. Calyx hairy, spreading widely, but scarcely reflexed. Seeds in a rough head, brown, shining, quite smooth, compressed, most like those of *bulbus*, but more ovate, and with a longer, more recurved, and somewhat hooked, beak. Their edge is green, simple, not tri-radiated as in the last.

53. *R. polyrhiza*. Many-rooted Siberian Crowfoot. Wild. n. 42. Lamarck Díct. n. 38.—Radical leaves palmate, with wedge-shaped, three-toothed segments; flower-leaves sessile, tinged. Stems many-flowered. Root fasciculated. Calyx spreading. Seeds ovate, compressed, smooth, with a blunt beak.—Native of Siberia. Root fasciculated, perennial. Radical leaves like *R. federatus*, three-toothed; their lateral lobes two-lobed, wedge-shaped like the leaf itself, their segments bluntly three-toothed. Stem a finger’s length, simple, erect or ascending, two or three from one root. Stem-leaves sessile, tinged, wedge-shaped at the base; their segments linear, bluntish, entire. Flower-stalks two, three, or four, long, single-flowered, round, not furrowed, very finely downy like the stem. Calyx-leaves coloured, smooth, obtuse, spreading. Petals yellow, the size of *R. Flamula*. Fruit roundish. Seeds ovate, compressed, smooth, crowned with the permanent blunt stigma. Wildflower. By the above description this species appears related, in many points, to the last, though they can hardly be the same.

55. *R. prostratus*. Prostrate Crowfoot. Lamarck Díct. n. 35. Fl. Francof. n. 3. 197.—Leaves ternate, three-cleft, very hairy. Stems entirely prostrate, creeping, zig-zag. Calyx smooth.—Native of dry hilly places about Paris. Lamarck and Poiret esteem this a distinct species from the last, not only because its herbage is much smaller and more hairy, but because the *flames* are, even when in flower, entirely prostrate. We have never met with any thing answering to this description in England. The flowers are said to be Reliable *repens*, having likewise a smooth calyx. Our *repens* has hairs on that part.

56. *Q. intermedia*. Intermediate Crowfoot. Lamarck Díct. n. 44.—Lower leaves three-lobed, cut; upper somewhat fingered. Flower-stalks mostly solitary. Calyx reflexed. Seeds compressed, smooth. Root fibrous. Found at the borders of ponds in France, about Paris and at Fontainebleau. This plant, according to Poiret, is, as it were, intermediate between *bulbus* and *repens*, having besides, many characters in common with *prostratus*. The root is fibrous, fasciculated. Stems several, low, scarcely branched, almost leafless except at the bottom, weak, frilled, slightly downy, often forked above. Radial leaves on long stalks, almost smooth, in three rounded, often cut, lobes; the *flames* have three linear or lanceolate irregular lobes; the uppermost are very narrow, almost fingered. Flowers axillary, or terminal, two or three on each branch, on very long and slender, nearly smooth, stalks. Calyx-leaves reflexed at the time of flowering, as in *bulbus*, coloured, concave, bearing some very long hairs. Petals of a fine yellow, frilled, middle-sized. Fruit oval or globose. Seeds smooth, compressed, roundish, with a green border. We know nothing of this species but from the above description.

57. *R. lucidus*. Shining-leaved Crowfoot. Lamarck Díct. n. 36.—Leaves with three or five lobes, somewhat pinnatifid, shining, smooth. Stem erect, many-flowered. Calyx reflexed.—Supposed to be a native of the Levant; cultivated
in the botanic garden at Paris. Root perennial. Stems one
or two feet high, branched, leafy, very smooth, tender,
frayed. Leaves alternate, flat-topped, widely spreading, smooth,
shining as if varnished on their upper surface, divided into
three or five distantly dilated lobes, the two lowermost con-
tacted at their base, unequally cut, obtuse. Petals five-
flaked long, somewhat downy, dilated at their base into a broad
membranous expansion. Flowers numerous, situated at the ends,
as well as in the forks of the branches, on long, simple,
cylindrical, rather downy stalks. Calyx leaves coloured,
smooth, concave, reflexed after the flower expands. Petals
rather large, roundish, of a fine shining yellow. This plant
has some agreement with _Rappen_, from which it differs in
having entirely upright stems and a reflexed calyx, as well as
shorter more dilated lobes to the leaves. Such is Poiret's
account. This surely cannot be our _polysynthia_, n. 52, which
has hairy leaves, and no resemblance or affinity to _rappen_;
neither could the intelligent author have overlooked Turnei-
fort's synonym for that plant.

58. _R. polyanthemus_. Many-flowered Crowfoot. Linn.
28. Lamarck n. 41. Lob. 1c. 666. (R. fylveftris
fucundus; Dod. Pempt. 477. R. fylveftris caulis; Ger.
Em. 951, as to the figure. R. fylveftris; Tabern. Kreut-
terb. 107. 1c. 42. R. napellifolius; Crantz fef. 3. 90.
t. 4 f. 11. 13.) Leaves in five deep, repeatedly subdivided
lobes; segments all linear. Stem erect, many-flowered.
Flower-stalks furrowed. Calyx spreading. Seeds ovate,
bordered, comprefed, smooth.—Native of moor, elevated,
rich meadows, in Upland, and elsewhere in Sweden, but
rarely. _Linnaeus_. In Germany, and perhaps in Switzerland,
on the authority of various writers. Root perpendicular. Stem
erect, two or three feet high, branched, many-flowered;
leafy, clothed with upright, or somewhat spreading, hairs.
Radical and lower flower-leaves three inches wide, on long
very hairy stalks, divided to the very base into three lobes,
the lowermost ones nearly divided into the leaf, so that the
leaf may truly be called, in the strict sense, five-lobed;
each lobe is deeply, more or less repeatedly, cut, into three-
clut or alternate, linear, blunting, entire, single-rilled,
spreading segments, softly hairy on both sides, paler be-
neath: the uppermost leaves are nearly sessile, in about
three deep, linear, entire divisions. Flower-stalks long, ter-
mal, angular or furrowed, rough with upright hairs. Flowers
large, yellow, drooping, not closing, in wet weather,
according to _Linnaeus_. Calyx spreading, pale, ex-
ternally hairy. _Fruit globose_. Seeds ovate, short,
comprefed, smooth at the sides, bordered and roughish at the
edges, tipped with a broad, short, recurved beak. We
have described this from the authentic Linnaean specimen,
which seems distinct from the following, and anwers ex-
trmely well to the figure of _Tabernamontanus_ more espe-
cially, nor does it ill accord with that of _Dononcous_, re-
printed in Gerarde's herbal. The last-named author how-
ever certainly applies that figure to the common English _R.
acris_, which he says he found double. Hence some doubt
may arise whether the true _polyanthemus_ was ever cultivated
in England, as it seems to depend on Gerarde's authority
only for a place in Hort. Kew. We have never seen it
 alive. Possibly it may be found in a double state in some
old garden. The above description of the leaves, and the
greater size of the whole plant, will distinguish it from _acris._
The calyx is hairy in both, notwithstanding Willde-
now's remark to the contrary.

59. _R. acris_. Upright Meadow Crowfoot. Linn.
Curt. Mag. t. 215. (R. hortensis fucundus; Dod. Pempt.
426. R. pratensis, furcetis caulis; Lob. 1c. 665. R.
lentic; Trag. Hoff. 94.)—Leaves in three deep, wedge-
shaped, many-cleft, jagged; the lowermost ones deeply
divided. Stem erect, many-flowered. Flower-stalks round.
Calyx spreading. Seeds ovate, bordered, comprefed, smooth.

—Native of meadows and pastures in all the more northern
countries of Europe, very common in England, flowering
in June and July. The double-flowered variety is frequent
in gardens. The root is perennial, tuberous, with long
simple fibres. Stem erect, two feet high, round, frayed,
rough with spreading hairs below, and with close-prefted
ones above, branched, slightly leafy. Leaves hairy on the
leaves, less divided than in the leaf, and with broader, wedge-shaped,
by no means linear, segments: the upper ones linear, either
depthly three-clft, or simple. Flower-stalks round, not fur-
rowed. Calyx green, spreading, hairy. Petals bright shining
yellow. _Fruit globose_. Seeds much like the last.

A dwarf alpine variety was brought by Mr. Dawion
Turner from wet rocks, near the summit of Snowdon,
whose _fem_ is but three or four inches high, and bears but
one or two flowers. This when cultivated in a garden
gradually assumes the size and habit of the common kind.

60. _R. Breymius_. Woolly-furred Alpine Crowfoot.
Crantz Auctr, ffe. 2. 91 t. 4 f. 2. (R. Breymius, by
miife; Lamarck Dict. n. 59. n. 1170; Hall. Hoff.
v. 2. 72.)—Leaves deeply three-lobed, cut and toothed,
very hairy beneath. Stems spreading, few-flowered. Calyx
spreading. Seeds smooth. Receptacle woolly.—Native of
the Austrian and Swits Alps. Haller says it is the smallest
of all the species. The _fem_ is several, two or three inches
high, oblique, simple or somewhat branched, hairy, bear-
ing one or two flowers, which are of a varnished yellow.
_Radical leaves_ numerous, less deeply divided than in _acris_,
very hairy beneath. _Fruit globosum_. Seeds smooth, hooked.
Receptacle woolly, which Crantz says he had not observed
in other species, and by which we presume this is most effen-
tially distinguished, particularly from the above alpine
variety of _acris_. We have not met with a specimen, nor was
Mr. Davall acquainted with the plant of Haller.

61. _R. lappaceus_. Bur Crowfoot.—Leaves ternate; leaf-
lets falkked, three-lobed, sharply cut, hairy. Stem erect,
many-flowered. Calyx spreading. Seeds ovate, keeled, re-
ticulated, with elongated, revolute-pointed beaks.—Native of
Port Jackson, New South Wales; communicated by
Dr. White. This has much of the habit of _R. acris_, but
is very distinct. The _fem_ are a foot, or more, in height,
branched, roundish, rough with close-prefted hairs. _Radical
leaves_ numerous, on long hairy stalks, very hairy, about the
size of _acris_ or _reptus_, but remarkable for the partial stalks,
sometimes an inch or two long, that support the leaflets,
especially the terminal one; the _leaflets_ are broad, wedge-
shaped, more or less deeply three-lobed, coarfly and sharply
cut. The lower flower-leaves are narrower and less cut; the
upper entire and lanceolate; the uppermost all simple and
linear. Flowers larger than in _acris_, white in the dried
specimen, but perhaps yellow when fresh, finely veined, on
long, hairy, angular, terminal stalks. _Calyx spread-
ing_, clothed with long hairs. _Necros_ covered with a wedge-
shaped scale. _Fruit globose_. Seeds ovate, turgid, keeled,
reticulated with veins, smooth, each tipped with a prominent
angular beak, nearly its own length, whose point is strongly
recurred, and even revolute.

n. 46. Lamarck Dict. n. 39. (R. orientalis dulcis, doro-
nici radice; Tourn. Cor. 20.)—_Calyx spreading._ Flower-
stalk
RANUNCULUS.

Doronicum. Perennial. Leaves heart-shaped, three-lobed, toothed."—Native of Cappadocia. Root perennial, hard, the thickest of a goose-quill, and resembling the root of Döric umie. Radical leaves roundish-heart-shaped, with three very short lobes, all pointed, furnished with a few coarse teeth, and clothed on both sides with scented clove-preened hairs. Stem-leaf solitary,2 3, as well as the radical ones; and in the middle of the flower-flalk is a small, f-fife, lanceolate, entire leaf. Stem a span high, clothed with clove-preened hairs, either simple, or divided above the leaf, each flalk fingered. Crowfoot, the fize of R. polyanthemum. Fruit roundish. Seeds, comprised, hooked. Willdenow, from a dried specimen.

Calx spreading. Seeds ovate, comprised, with elongated, revolute-pointed beaks.—Native of Germany, France, Switzerland, Carniola, Greece, and North America. Mr. Pursh observed it in old fields and meadows, from Pennsylvania to Carolina, flowering from June to October. Dr. Sibthorp found it in shady wetter situations in the Peloponnesus, but most plentifully in the north of Greece, and with great reason concluded it to be the second R. lanuginosus of Dioscorides, with whose description it sufficiently agrees, except being mild, rather than very acrid, in febile qualities, if we may trust modern authors. Limneas distinguishes two varieties, between which we can discover no difference, and Haller unites them. The opinion of this great Swite botanist however loses some of its weight, by the doubt he expresses whether this plant be distinct from R. repens, n. 54, to which it has indeed a slight general resemblance, though differing totally in its upright stem, distinct of runners; its very soft silky leaves, by which this plant is known at once from every other European R. lanuginosus; and the revolute tapetor points of its seeds, which nearly agree with lapaccus in that respect; but the seeds themselves are comprised, and, as far as we can see, distinct of reticulated veins. The root is perennial, with many long, stout, cylindrical, f-fihy fibres, or perhaps slender knobs, intermingled with capillary branched radicles. Stem 12 or 18 inches high, branched, leafy, round, clothed with long, spreading, or deflexed, hairs; its base purplish, as are also the long hairy flower-flalks of the radical leaves. These and the lower flower-flalks are three inches wide, divided all half way down into five or seven broad, sharply notched lobes, whose close limits have a pale spot, with a purple vein, adjoining to their termination. The upper leaves are deeply three-leaf, with ovate and toothed, or lanceolate and entire, lobes. Flowers yellow, much like those of acris. Calyx hairy, spreading. Fruit globose. Seeds with awl-shaped, strongly revolute beaks, by which this species is clearly distinguishable from repens, polyanthemum, acris, if such a mark were necessary, and by which it forms a chain of affinity between those species and our lapaccus. It is somewhat remarkable that R. lanuginosus has not been found in Britain, and still more so, that any obscurity should envelope the botanical history of so distinct a species.

64. R. sericus. Silky Crowfoot. Lamarck Dict. n. 26.—Leaves ternate, very silky; leaflets wedge-shaped, deeply three-leaf, jagged and toothed. Stem erect, many-flowered, silky. Calyx spreading. Seeds ovate, comprised, with short erect beaks.—Gathered in the Isle of Bourbon by Commeron, from whom we have specimens. Roots, as well as the general habit and size of the plant, like the last, but the whole herb is much more densely clothed with hairy silky hairs. The leaves are ternate, some of them almost twice ternate; their lobes deeply and repeatedly cut, in a radiant manner, with sharp teeth. Flowers like the last. Fruit ovate. Seeds with broad straight beaks, longer, and not so much curved or hooked, as even those of acris.

65. R. tomentosus. Shaggy Crowfoot. Lamarck Dict. n. 70. Pursh n. 17.—Leaves downy, three-lobed or notched; the uppermost oval, entire. Stem reclining, somewhat creeping, shaggy, one or two-flowered. Calyx hipped, slightly reflexed.—Gathered in North Carolina, by M. Bofc. A small, almoost creeping, very hairy plant, with fibrous roots. The flesms are very low, and nearly prostrate, ascending at their extremities, two or three inches long, tender, covered with whitish tufted hairs, divided in two rows. Leaves falked, thick, downy, generally with three lobes, which are either distinct or confluent; some leaves are merely crumate and rounded. Footflalks long and hairy. The uppermost flem-leaf is fihile, oval, acute, entire. Flowers one or two, on terminal, unequal, simple falks, clothed with two rows of hairs. Calyx hipped, a little reflexed. Petals white or yellowish, rounded at the end. Poiret. We have seen no specime, nor did Mr. Pursh meet with the plant himself.

66. R. marylinscas. Maryland Crowfoot. Lamarck Dict. n. 69. Pursh n. 18. Leaves ternate, three-lobed, acute, cut, pale and nearly smooth beneath. Stem simple, almost naked, downy. Calyx smooth, reflexed. Found in shady woods, from Pennsylvania to Virginia, flowering from May to July. Pursh. Root fibrous, perennial. Stems simple, erect, downy, slender, about ten inches high; Poiret by mistake, as prelume, says ten feet. Leaves radical, on long downy falks, ternate; the two lateral ones opposite, falked; all with three confluent, lancolate, acute, cut lobes; their upper surface green; the under paler and whitish, almost smooth. There are no other flen-leaves than what fland almost fihile, at the base of the flower-flalks, and either have three or five fihile irregular lobes, or are simply cut. Flowers two or three, terminal, on short, fcarly downy falks. Calyx fihile, reflexed. Petals rather large, oval, rounded at the end, pale yellow. Poiret.

67. R. recurvatus. Curved Crowfoot. Lamarck Dict. n. 65. Pursh n. 19.—Leaves in three deep, acute, cut, wedge-shaped lobes. Stem many-flowered. Calyx and corolla reflexed. Petals nearly linear. Seeds comprised, dotted, with revolute, awl-shaped beaks.—Native of shady woods, from New York to Carolina, flowering from June to August. Pursh. We received specimens from the Rev. Dr. Muhlenberg, of Lancaster, Pennsylvania. The root is perennial. Stems a span high, very hairy; branched and leafy at the upper part. Leaves two or three inches wide, rather hairy, on very hairy falks; their fide-lobes for the most part deeply cloven. Flowers flalked, small. Calyx pale-purplish, ribbed, clothed with fine long hairs. Petals small, narrow, almost white. Fruit globose. Seeds ovate, lenticular, minutely dotted, smooth, with fnder, revolute-pointed beaks.

68. R. septentrionalis. Smooth North-American Crowfoot. Lamarck Dict. n. 64. Pursh n. 20.—Leaves ternate, membraneous, smooth, deeply lobed, acute, cut. Stem two-flowered, hairy, like the base of the footflalks. Calyx reflexed.
RANUNCULUS.

reflexed. — Native of North America. Described by Poiret from Lamarck's herbarium, and adopted by Pursh. Root perennial, fibrous, falcate curled. Stems nearly simple, hollow, eight or ten inches high, almost leafless; downy in their lower part. Leaves falcate, thin, smooth, composed of three falcate leaflets, the central one having three deep spreading lobes, the others often but two; all sharp, cut and toothed. There is usually but one stem-leaf, which is nearly sessile, serrate, with narrower segments. Footstalks long, slender, more hairy towards their base. Footstalks two, terminal, unequal, very slender, smooth, each bearing, about half way up, one small linear leaf. Calyx reflexed, coloured, smooth, except a few terminal hairs, deciduous. Petals pale yellow, rounded; Fruit small, globular. Seeds nearly orbicular, lenticular, with sharp straight beaks. Poiret.

69. R. bifidus. Hifpid American Crowfoot. Michaux Boreal-Amcr. v. 1. 321. Lamarck Dict. n. 27. Pursh n. 21.— Very hairy, erect. Leaves ternate, sharply lobed. Stems few-leafed; leaflets below. Calyx cleft-preliced. Seeds obovate, with awl-shaped, inflexed beaks. — Found in wet fields, and on the banks of ditches, from Virginia to Carolina, flowering from June to August. Root perennial. Flowers small, pale yellow. Pursh. — A specimen liner to Sibthorpe, as akin to his langeineus, but distinct, answers very well to the characters of Michaux, and we have taken from that specimen the above account of the seeds. The flower is nearly as big as acris. Whole herbage, especially the footstalks, very hairy.

71. R. multifidus. Many-leaf Araban Crowfoot. Forsk. Ægypt.-Arab. 102. Lamarck Dict. n. 67. — "Leaves many-leafed; the lower ones pinnated. Stem many-flowered. Calyx the length of the corolla. Seeds ovate, acute." — Gathered by Forskall, in ditches near the town of Taes. He describes the stem two feet high, erect; round in the lower part; falcate; above; hairy. Fruit oval. We have no other authority, than the authors quoted, for this species or the lait.

72. R. pedatifidus. Radiating-leaved Crowfoot. — Leaves deeply pedatifid, with linear, obtuse, divided or three-leafed, radiating, entire segments. Stem one or two-flowered. Seeds ovate, hairy, with small recurved beaks.— Native of Siberia. Four specimens from that country are in the Linnaean herbarium, but the species, though very distinct, appears never to have been described. Root perennial, of many long, cylindrical, fleshy fibres, and crowned with numerous capillary remains of old footstalks. Stem a span high, erect, round, falcate, leafy, fimbriate, or divided, clothed with long, soft, lax hairs. Radial leaves on long hairy stalks, deeply cut, in a pedate manner, into five, seven, or more, narrow, linear, obtuse, elegantly radiating segments, some of which are deeply three-leafed, and their lobes again cleft, others merely divided, and others undivided; all entire at the edges, and somewhat hairy on both sides, with long, lax, white hairs. The stem-leaves are mostly fimbriate, fimbriate, divided; the uppermost in three, rarely more, deep, linear, simple segments. Flowers apparently yellow, the size of R. acris. Calyx woolly at the base; its segments partly dilated and coloured, all shorter than the petals, and closely preliced to their under side. Fruit ovate. Seeds not very numerous, ovate, hairy, with short, awl-shaped, reflexed beaks.

73. R. echrophyllus. Chervil Crowfoot. Linn. Sp. Pl. 782. Willd. n. 48. Lamarck Dict. n. 32. (R. tenifolius luteus, grumofa radice, foracterinis feu italicus; Bar. t. 581? bad.) — Leaves thrice compound, with linear segments. Stem silky, with few flowers. Calyx reflexed, hairy. Root with tapering fleshy fibres.—Native of the south of Europe. The only certain specimen of this plant, that has ever come under our observation, exists in the Linnean herbarium. The root consists of numerous, long, fleshy, gradually tapering, downy fibres. Stem erect, about 1 span high, slender, fimbriate, slightly leafy, branched, bearing three or four flowers. Radical leaves several, falcate, repeatedly ternate, with numerous linear, or somewhat lanceolate, entire segments, hairy beneath. Footstalks an inch and half long, hairy; dilated, membranous, and ribbed at the base. Stem-leaves few, much leps compound, and often nearly fimbriate. Flowers solitary, on long, terminal, simple, hairy, quadrangular footstalks. Calyx strongly reflexed, coloured; externally hairy. Petals yellow. Fruit not sufficiently advanced to be described. At the back of this specimen Linneus has written Ranunculus lycicus, pulsatillifolio, T. Cor.; but there is no such pellage in Turnfort's Corolla, nor any thing to which it can refer, except R. lycicus, pulsatillifolio, flor evaro, a species unknown to us.

A very different plant from the true R. echrophyllus, was given by the abbe Parreurt to the younger Linneus, under that name. It seems rather to be flabellinus, n. 52, a species allied, in many points, to what we are describing.

74. R. milfoil. Milfoil Crowfoot. Vahl. Symb. v. 2. 63. t. 37. Desfont. Atlant. v. 1. 441. t. 1. Wild. n. 49. Lamarck Dict. n. 33. Sm. Fl. Grec. Sibth. t. 521, unpublished. (R. montanus leptomiphyllon, aphodeli radice; Columna. Ecphr. 312. t. 311.) — Leaves thrice compound, with elliptic-linear segments. Stem silky, with few flowers. Calyx erect, somewhat hairy. Root with ovate knobs.— Native of Italy, Greece, Syria, and Barbary. The root, in Dr. Sibthorp's specimens, consists of many oval fleshy knobs, scarcely half an inch long, intermixed with fibres. Columna describes and delineates the fibres as terminating the knobs; a very material difference. The floem, in the Greek and Italian specimens, is simple and fleshy-vascular; in the more luxuriant ones from Aleppo and Tunis, somewhat branched, bearing two or three flowers. The stem-leaves are more numerous, as well as more compound, than in the last. Flowers large. Calyx closely preliced to the corolla; sometimes nearly fimbriate. Fruit oblong. Seeds with small recurved beaks. We can scarcely doubt, notwithstanding the above-mentioned dive-fity respecting the root, that the synonym of Columna belongs to the present, rather than the foregoing, species.

75. R. oxyterpus. Sharp-leafed Crowfoot. Willd. n. 51. Lamarck Dict. n. 37. — "Radical leaves oblong, obtuse, deeply and unequally toothed; stem-leaves fimbriate, fingered, cut. Seeds awned." — Native of Siberia, near the river Terek. Root apparently annual. Radical leaves falcate, ovate, obtuse, with unequal deep teeth; hairy, like their footstalks, on both sides. Stem erect, branched, hairy, a foot or more in height. Stem-leaves dilated; the segments of the lower ones unequally pinnatifid; of the upper linear and entire. Calyx reflexed. Corolla yellow, the size of R. bulbiv. Fruit elliptical. Seeds rather compressed, acute,
acute, with upright, awl-shaped, brilly points. Willdenow.

77. R. muricatus. Spreading prickly-Crowfoot. Linna. Sp. Pl. 780. Wild. n. 53. Lamarck Dict. n. 75. Ait. n. 53. Pursh n. 24. Sm. Fl. Grac. Sibth. t. 522, unpublished. (R. cicutaeus echinatus latifolius; Alpin. Exot. 263. t. 265. R. Apulei queubidum; Cluf. Hift. v. 1. 233. R. parvis echinatus; Ger. Em. 965. R. paullus echinatus; Bauh. Hift. v. 3. 846. Penf. Peruv. 58. t. 18. f. 1.)—Leaves simple, three-lobed, notched, blunt-tipped, smooth. Stipulae dillantly fringed. Seeds prickly at each side. Stem diffuse. Native of water places in various parts of the south of Europe; frequent in Greece. It occurs also in North America, in old fields, from Virginia to Carolina, flowering in June and July, according to Mr. Pursh. The root is annual, consisting of numerous long fibres. Herb smooth and succulent, bright green. Stems several, various in length, spreading, and mostly procumbent, leafy, round, fibrous; pubescent in the lower part. Leaves an inch and a half to three inches wide, with three rather deep lobes, broadly and irregularly notched. Flowers from one to four inches, or more, in length, with a concaue spreading base, bordered with a membraneous stipula, whose edges are regularly fringed with dillant hairs. Flowers the size of the last, yellow, solitary, on auxiliary flasks, rather shorter than the leaves. Calyx reflexed, nearly, or quite, smooth. Petals ovate, almost twice as long as the calyx, at least in the European specimens, though they appear to be but of the same length in American ones. Fruit capitata. Seeds large, ovate, compressed, with broad, awl-shaped, angular, somewhat recurved beaks; their sides covered with smaller, more uniform prickles, than in R. arvensis. Commision gathered, by the sea-shore at Monte Video, a variety of this with more luxuriant herbage, and smaller flowers, of which Ventenat makes a species of the name of ventriculifolium, founding its character on the inflated bases of the footstalks, of which, however, we can see nothing, in our original specimens from Thouin's herbarium. Its stipulae are fringed precisely as in our European muricatus, to which we agree with Poiret in referring it, though we can scarcely do the fame by the following.

78. R. echinatus. Dwarf Prickly-feeding Crowfoot. Venten. Jard. de Cels t. 73. Pursh n. 25. (R. muricatus; Lamarck Dict. n. 75.)—Leaves simple, three-lobed, notched, smooth. Stipulae bearded at the summit. Seeds prickly at each side. Stem erect, branched. Found by M. Bœé, near Charlestown, South Carolina. This seems to differ from the last, in its short, stilted, upright stem; but more especially, if Ventenat's plate and description is correct, which we cannot doubt, in having each footstalk crowned with a tuft of hairs, instead of being dillantly fringed throughout. The petals are said to be larger than those of the American variety, at least, of muricatus; but that circumstance is of small moment here, as to a specific distinction.

80. R. orientalis. Spinous Oriental Crowfoot. Linna. Sp. Pl. 781. Wild. n. 55. Lamarck Dict. n. 71. (R. lebisch, pulatifolium folio, flore magnio; Tourne. Cor. 20.)—Leaves deeply laciniate, acute; all stilted. Stem branched. Calyx reflexed. Fruit cylindrical. Seeds dotted; their beaks recurved and spinous.—Native of the Levant. Root annual. Stem various in luxuriance, filky, leafy; in the Linnaean specimen much branched and divaricated, with many flowers, most of which, when half opened, composed in general of three deeply laciniate, often pinnate, acut, hairy leaflets. Flowers large, pale yellow, on long, stout, simple, lateral or terminal, solitary, spreading stalks. Flowerstalks reflexed that decidually reflexed, nearly smooth. Fruit three quarters of an inch long, slightly elliptical, obstate. Seeds in many rows, compressed, minutely dotted at each side, gibbous at the base, each terminating in a very broad, rather short, compressed, recurved, spinous-pointed beak. We know of no figure of this or the following.

81. R. grandiflorus. Large-flowered Oriental Crowfoot. Linna. Sp. Pl. 781. Wild. n. 56. Lamarck Dict. n. 63. (R. orientalis, acorni folio, flore luteo maximio; Tour. Cor. 20.)—" Stem erect, two-leaved. Leaves many-cleft; those of the stem alternate, sessile."—Gathered by Tournefort in the Levant. We have seen no specimen. Willkewen marks this as a perennial species, and indicates his having seen it in a dried state. We regret that he did not subjoin a description of the plant, the Linnaean specific character being very insufficient. What Poiret has given is evidently compiled from the short materials furnished by Linnaeus and Tournefort. The Abbé Sclímini is said to have gathered R. grandiflorus near Conflantimpole; on whose authority it finds a place in Prodr. Fl. Grac. v. 1. 385.

(Melampyrum latum; Ger. Em. 90. Lob. t. 37.)—
Leaves linear-wedge-shaped, in three deep many-lobed
loves. Seeds with fleshy-leaved beaks. Stalks radical, single-
flowered. Native of corn-fields in the south of Europe, and
the Levant; cultivated by Miller at Chelsea in 1739.
A small annual, flowering in the early part of summer.

83. R. polyphyllus. Many-leaved Water Crowfoot.
"Waldl. et Kitaib. Hang." Willd. n. 58. "Leaves
under water oblong, flanked, capillary; floating ones wedge-
shaped, three-lobed; those above the water elliptical.
Stem erect."—Native of the waters of Hungary. Annual. Stem
nine inches high, erect; branched in the upper part. Leaves
that are under water very numerous, entirely covering that
part of the stem, the length of the nail, each supported by
a capillary footstalk an inch long; the floating
leaves small, wedge-shaped, three-lobed, entire, as long
as the former, their footstalks thicker and shorter. Branches
an inch long, erect, rising above the water, and bearing
elliptical obtuse leaves, tapering each way, from four to
six lines long, on short footstalks. Flowers extremely small,
yellow. Willdenow.

Dalech. Hist. 1031—(R. bderacae rivulorum in exten-
da, atrum mollis notatus; Bumel. Hist. v. 3. 774.)—Leaves
smooth, roundish, kidney-shaped, with three or five entire
loves. Stem branching. Stamens from five to ten. Seeds
corrugated.—Native of watery places, on a sandy or gravel-
ly soil, in England, Germany, France, &c. flowering
from May to August. Roots fibrous, perennial. Stems
either creeping or floating, prostrate, branched, round,
smooth, and succulent. Leaves flanked, smooth, and
shining, nearly uniform; often blackish in the disk. Flowers
very small, on simple, axillary or lateral, stalks. Petals
linear-oblong, rather exceeding the calyx in length, white,
with yellow claws. Stamens scarcely ever more than ten.
Fruit globose. Seeds ovate, incurved, somewhat compressed,
with a very small indented beak, and numerous, lateral,
corrugated or reticulated veins.

Engl. Bot. t. 101. Ger. Em. 829.—Leaves capillary un-
der water; above somewhat petalate. Stamens numerous.
Seeds corrugated.—Native of pools, ditches, and rivers,
thoroughout Europe, mantling the surface with its copious
white blossoms, in the early part of summer. The roots
are long, fibrous, and perennial. Stems floating under
water, long, round, branched, leafy. Leaves flanked,
smooth; the uppermost floating, usually petalate, with
various blunt notches; the next deeply three-lobed, or even
ternate; the lowermost immered, repeatedly three-elft,
with innumerable capillary segments. Flowers floating on
long simple stalks, opposite to the leaves. Petals obvate,
much longer than the calyx, white, with yellow claws. 
Nectary tubular. Stamens thirty or more. Fruit like the
leaf, but the seeds more numerous, and generally bluntly,
somewhat obvate.

Varieties, as we deem them, of this species are, 1st, that
whose leaves are all immered, and entirely capillary,
figured in Ger. Em. 827. f. 3; 2dly, the circinatus of Sillth.
Oxon. 175, figured in Phyt. t. 55. f. 2, whose
leaves are all likewise in capillary division, but finer and
smaller than the former: 3dly, the fluitatis of Willdenow,
n. 61, puncelalobus of Desfont. Atlant. v. 1. 444, figured
in Fl. Dan. t. 376, whose leaves are not only in capillary
segments, but considerably elongated, by the influence,
as we conceive, of the running water, in which this fort is
always found. The seeds indeed are not truly, in our
specimens of this last variety, but naked, as in bderacae,
which species agrees with every variety of aquatilis, in
the corrugations of the seeds, as above described.

We have thus added twenty-four species to Willdenow's
number, following his arrangement, for the present at least;
not only for the convenience of our readers, but because
it would be very difficult to make a perfect one on any
known principles; the several species being allied by so
many characters, and so dissimilar in others, that nothing
could be more precarious than to seek the clue of nature
through such a labyrinth. The seeds perhaps ought to
form the basis of a specific arrangement, if they might not
even lead to generic distinctions.

No small curiosity in the history of this genus is the
R. olurus, of Poiret in Lamarrack's Dict. n. 72; which, by
his description, proves to be no other than Gymnostyle pen-
roperma of Jullieu. (See Gymnostyle.) The pulicis of
Poiret, n. 82, appears to us a variety of aquatilis, growing
in shallow, and perhaps fluctuating, waters; whence,
tho might its leaves are all deeply cut, their segments are
not quite capillary, but linear and obtuse. We have Swifs
specimens answering to this author's description.

Ranunculus, in Gardening, contains plants of the hardy,
herbaceous, perennial kind, of which the species cultivated
are, the Perian crowfoot, or garden ranunculus, (R. aflat-
us); the aconit-leaved crowfoot (R. aconitifolius); the
upright meadow crowfoot (R. ocris); the creeping
crowfoot (R. repens); and the embracing-leaved crowfoot
(R. amplexicaulis). But there are other species that may
be cultivated for variety.

Of the first species the varieties are exceedingly
numerous, being sometimes divided into two clades, as tho old
Turkey-kinds, and the Perian kinds, the varieties of the
latter amounting to many hundreds, and being considerably
more various, rich, and beautiful in colour than tho of the
others.

But in the former of these sorts they rise with a strong
generally unbranching stalk a foot high, terminated by one
double flower, sometimes emitting one or two smaller
ones from its sides, and of which there are red-flowered,
scarlet-flowered, yellow-flowered, and scarlet turban-flower-
ed, &c.; but being seldom tinged with different colours, as
in the Perian kinds.

And in the latter kind the plants rise eight or nine inches
high, generally branching from the bottom, producing
from five to ten to twenty or more flowers on each root,
and of which there are single-flowered, semi-double-flowered,
full-double-flowered, large and full like a double rose, being
generally filled with petals to the very centre, forming a
regular globular body, of admirable elegance, of all sorts of
the most beautiful colours in different varieties, and of
numerous degrees of deeper and lighter shades, tinges, and
tings in the several colours. Indeed Martyn observes,
that the varieties produced of late years from the seeds of
semi-double flowers are unbounded; and that Mr. Mad-
dock remarks that they are more numerous than any
other
other flower. Accordingly his catalogue, he says, boasts nearly eight hundred, all with their proper names; ranged under the heads of—dark and dark purple; light purple and grey, &c.; crimson, &c.; reds, &c.; roly, &c.; orange, &c.; yellow and yellow spotted, &c.; white and white spotted, &c.; olive, &c.; purple and coffee-striped, &c.; red and yellow-striped; red and white striped.

And according to the above flower gardener a fine ranunculus should have a strong bright stem from eight to twelve inches high. The flower should be of an hemispherical form, at least two inches in diameter, consisting of numerous petals gradually diminishing in size to the centre, lying ever near to each other, so as neither to be too close nor too much separated, but having more of a perpendicular than horizontal direction, in order to display the colours with better effect. The petals should be broad, with entire well-rounded edges; their colours dark, clear, rich or brilliant, either of one colour or variously diversified, on a white, sulphur or fire-coloured ground, or else regularly striped, spotted or mottled, in an elegant manner.

In the second species there is a variety with double flowers, which has been obtained by seeds, and is preferred in many curious gardens for the beauty of its flowers. It is by some gardeners called the Fair Maid of France. The root is perennial, and composed of many strong fibres: the leaves are divided into fine lanceolate lobes: the four side-lobes are upon footstalks coming from the side of the principal stalk, and the middle one terminates it; they are deeply serrate, and have several longitudinal veins. The flanks rise a foot and half high, and branch out at the top into three or four divisions, at each of which there is one leaf, of the same shape with the lower, but smaller. The flowers are pure white, and very double, each standing upon a short foot-stalk. The flowers come forth in May.

In the third sort there is also a variety with double flowers, which is the most generally cultivated in the garden. It is frequently among other herbaceous perennials, under the name of Yellow Bachelor's Buttons.

And in the fourth species there is a variety with double flowers, which is the root cultivated in the gardens for its ornamental effects.

Method of Culture. — The first sort and different varieties may be readily increased by the off-shears taken from the root, and new varieties may be raised from seeds. In the fright of these methods the off-shears should be separated from the roots in dry weather, in the latter end of summer, when the flowering is over, and the stems and leaves are declining, being placed in bags or boxes, in a dry place, till the autumn, when they should be planted out in rows six or eight inches apart, and six of them to each, in separate beds, prepared with light sandy earthy compost, to the depth of two or three feet; taking care to protect them carefully from the frost during the winter. When the buds begin to break through the ground they should be kept perfectly clear from weeds, protecting them from frosts; and when they have flowered and the stems are decayed, the root should be taken up; cleared from dirt, and placed in bags or boxes till the autumn, when they must be planted again.

But in the second mode, the seed should be collected from the best plants of the semi-double kinds, and be sown in flat pans or boxes, filled with light rich earth, in August, covering it in about a quarter of an inch thick with the same of earth, placing them in a shady situation, so as to have little of the morning sun. The pots should remain here till the beginning of October, when the plants sometimes appear, though it is often later before this happens, when they should have a more open exposure with the full sun, but when frost is apprehended, they should be removed under a common hot-bed frame, being only covered in the nights and bad weather with the glasse, guarding them well against rains and frost. In the spring following they should be exposed to the open air, being very lightly refreshed with water, having a situation to enjoy the morning sun; and when their leaves and stems begin to decay, the roots may be taken up, dried in a proper place, and then put up in bags to be planted out in the same manner as the old roots in October.

In the following summer they will produce flowers; when such as are good should be marked, and the others removed from them. The plants intended to flower should not be suffered to run to seed, as roots which have produced seeds seldom furnish fine flowers afterwards. The disappointments experienced in purchasing these roots, chiefly depend upon this circumstance.

It may be noticed that the roots intended for the borders should be planted towards the spring in little clumps or patches, three, four, or five roots in each, putting them in either with a dibble or trowel, about two inches deep, and three or four inches in each patch, and the patches from about three to five or ten feet distance, placing them in a varied manner in the borders.

And in regard to their general culture after planting, the forward autumnal-plantet roots of the choice sorts in beds as have shot above ground, should in winter, where convenient, have occasional shelter from hard frosts, by mats supported on low hoop arches; or in very severe weather be covered close with dry long litter, removing all covering in open weather; and in the spring, when the flower-buds begin first to advance, shelter them in frothy nights with supported mats, suffering them, however, to be open to the full air every day; but the latter plantings, that do not come up in winter, or very early in spring, while frothy nights prevail, will not require any protection, and all those distributed in patches about the borders must also take their chance in all weathers: those of the different feasons of planting will succeed one another in flowering from the beginning of April until the middle of June, though the May blow generally thaws to the greatest perfection. After the blow is past, and the leaves and stalks withered, the roots should be taken up and dried in the shade; then cleared from all off-shears and adhering mould, putting them up in bags or boxes till next planting season, when they must be planted again, as directed above.

But in each season of planting, it is highly necessary, in the principal fine varieties, to put them either in entire new beds, or the old ones refreshed with some fresh rich earth or compost, working the old and new well together, in order to invigorate the growth of the plants.

All the other species are capable of being easily raised by the roots, which should be flipped or parted in autumn when past flowering, or in the spring before they begin to shoot, and the slips be either planted at once, where they are to remain, or in nursery-rows for a season, then planted out finally. They succeed in any common soil and situation, and may be dispersed about the different flower-borders and clumps, where they constantly remain, only trimming them occasionally; and once in a year or two, or when they have increased to large bunches, taking them up in autumn or spring, to divide them for further increase, replanting them again directly.

In saving seed for raising new varieties, it must be suffered to continue on the plant till it becomes brown and dry,
dry, then be cut off, with the heads, and spread upon paper, in a dry room, exposed to the sun, and when quite dry, be put into a bag, and hung in a dry place till it is wanted.

All these plants are highly ornamental; the frits ftort in beds and pots, and the other in the borders, clumps, and other parts of pleasure-grounds.

**Ranunculus Viridis**, in Zoology, the name of an animal common in many parts of the world, and usually known by the name of the tree-frog, or rana arborea.

The creature is easily distinguished from the common frog, by its being much smaller, and of a green colour. It usually fits upon the leaves of trees and shrubs, and makes a great noise in an evening; but that is rather like the finging of a small bird than the croaking of a frog.

These creatures have been kept alive many years together in glass vessels, giving them flies and other small insects; and in winter, when these are scarce, they usually become very lean and feeble; but in summer, when they are plentiful, they will grow fat again, as if at their liberty. This is esteemed a poisonous creature. Ray. See Rana.

**Ranz des Faches**, a celebrated air among the Swifts, played upon the bagpipe by the young cow-keepers on the mountains. The air will be found on our music-plates. In the article Music, the powerful effects of this tune are mentioned, from Rouleau's Dict. de Mufique.

**Raocondna**, in Geography, the site of a diamond-mine in Hindooftan, placed in Mr. Montreuer's map about 15 geographical miles to the west of Ralicotte, and 12 from the north bank of the Kilttnah, but Mr. Rennell does not know what authority he has for this position. Tavernier, who visited Racondna, gives its distance from Golconda at 17 gos, of 4 French leagues each. He crossed a river that formed the common boundary of Golconda and Vishnapur, about four gos, or more, before he came to Racondna; and this river can be no other than the Beemah, which to this day forms the eastern boundary of Vi-shipour, and paffes about 80 or 82 miles to the west of Golconda, crossing the road from it to Ralicotte. If we reckon the 82 miles at 13 gos, that is, forming a fcale from the distance between Golconda and the river Beemah, each gos will be 6.3 geographical miles in horizontal distance (or nearer three than four French leagues); and Racondna will be placed about 25 geographical miles on the W. of the Beemah, or 11 E. of Ralicotte.

**Raon l'Etapp**, a town of France, in the department of the Vosges, and chief place of a canton, in the district of St. Die, on the Meurte; 7 miles N. of St. Die. The place contains 2528, and the canton 5300 inhabitants, on a territory of 70 Kilometres, in 5 communes.

**Rouda**, or Roudd, denoting garden, an island of Egypt, in the Nile, in front of Old Cairo, about 500 yards in breadth, where is built the Mekiia, signifying measure, or Nolometer, a pillar, by the gradations on which the rife of the Nile is measured.

This island is called Roud, or gardens, because it is laid out in gardens, and inhabited only by gardeners.

**Rauttiy**, a town of Hindooftan, in Malwa; 20 miles N.N.E. of Tanda.

**Rapa**, in Botany, (an ancient name, of whose etymology no plausible account has come to our knowledge,) the Turnip. See Brassica, species 7.

**Rapapao**, in Geography, a town of America, in New Jersey; 30 miles S. of Woodbury.

**Rapacious Animals**, in the general, are such as live upon prey.

Vol. XXIX.

---

Naturalists divide birds into rapacious, carnivorous, and frugivorous.

The characteristic notes of rapacious birds, which are the Accipitres of Linnaeus, are, that they have a great head, and a short neck; hooked, strong, and sharp-pointed beak and talons, fitted for tearing flesh; strong and brawny thighs, for striking down their prey; a broad thick fleshy tongue, like that of man; twelve feathers in their train; and twenty-four flag-feathers in each wing, and the two appendices, or blind guts, are always very short.

Rapacious birds have a membranous stomach; and not a malleable one, or a gizzard, such as birds which have live on grain.

They are very sharp-fighted, and gather not in flocks; but, generally speaking, are solitary; though vultures will fly fifty or sixty in a company.

**Rapakivi**, in Mineralogy, a name given to the aggregate of felspar and mica: its colour is brown, or brownish-red; it moulders by exposure to the air, but that is only when the mica is in excess. When the felspar exceeds, it forms a durable stone, called in Italy "Granitone." Kirwan.

**Rapallo**, in Geography, a town of the Ligurian republic, situated on a bay to which it gives name; 12 miles E.S.E. of Genoa.

Gen. Ch. Col. Periandth inferior, minute, of one leaf, with five or six teeth, permanent. Cor. of one petal; tube very short; limb in five or six deep roundish segments. Stam. Filaments five or six, inserted into the tube at the base of each lobe of the limb; anthers oblong, quadrangular, of two cells. Pet. Germin superior, roundish, of five or six cells; style very short; stigma obtuse. Peric. Drupa globular, of one cell. Seed solitary, globulo.

1. R. guianensis. Aubl. Guian. t. 46. (Samara flori- bunda; Willd. Sp. Pl. v. 1. 665.)—Native of thickets, in the skirts of meadows, in Cayenne and Guiana, bearing flowers and fruit in December. A small tree, whole trunk is five or six feet high, and four or five inches thick, crowned with branches; the wood white, not very compact. Leaves alternate, on short flanks, obovate, bluntish, entire, smooth, two or three inches long, with one rib, and many transverse veins feebly visible when fresh. Flowers capiuous, small, white, in dense lateral tufts. Fruit violet-coloured.—Mr. Brown, in his Prodromus Nov. Holl. v. 1. 533, speaks of this shrub as belonging to the genus Myrsine, see that article; consequently Jullieu was most correct in hinting its affinity to its Sapota, an order from which Ventenat and Brown have separated their more recent one of Myrsine, to which we refer the reader.

**Rapax**, in Ichthyology, a name given by Schoneveldt to the corvus pitis of some writers, a species of chub or cyprinus, called rafpe by the Germans, and by Gfener and others capito fluvilirius rafpe.

**Rape**, Rapius, in Law, a ravishing; or the having carnal knowledge of a woman by force, and against her will.
RAP

If the woman conceived, the law formerly esteemed it no rape; from an opinion, that she cannot conceive, unless she confented. But this opinion has since quizzed. Coke on Litt. lib. ii. cap. 11.

This crime, by the Jewish law, Deut. xxii. 25. was punished with death, in case the damsel was betrothed to another man; and in case she was not betrothed, then a heavy fine of fifty shekels was to be paid to the damsel's father, and she was to be the wife of the ravisher all the days of his life; without that power of divorce, which was in general permitted by the Mosaic law.

The civil law (cod. 9. tit. 13.) punishes the crime of ravishment with death and confiscation of goods; including under this crime both the offence of forcible abduction, and also that of forcibly dishonouring; either of which, without the other, is in that law sufficient to constitute a capital crime. And the fleeing away a woman from her parents or guardians, and debauching her, is equally penal by the emperor's edict, whether the consent, or is forced.

Rape was punished by the Saxon laws, particularly those of king Athelstan, with death; which was also agreeable to the old Greeks or Scandinavian constitution. Instead of this, another punishment was instituted by William the Conqueror, viz. castration and loss of eyes, which continued till after Bredon wrote in the reign of Henry III. But it was then the law, and still continues in appeals of rape, that the woman should immediately after go to the next town, and there make discovery to some credible persons of the injury she has suffered; and afterwards should acquaint the high constable of the hundred, the coroners and the sheriff, with the outrage; the time of limitation for this purpose was by flat. Welfm. 1. cap. 13. extended to forty days. But there is now no time fixed; for as it is now usually punished by indictment at the suit of the king, the maxim of law takes place, nullum tempus occurrat regi: however, the jury will rarely give credit to a flat complaint. During the former period it was also held for law, that the woman (by consent of the judge and her parents) might redeem the offender from the execution of his sentence, by accepting him for her husband, if he also was willing to agree to the exchange, but not otherwise.

In the 3 Edw. I. by the flat. Welfm. 1. cap. 15., the punishment of rape was much mitigated: the offence being reduced to a trespass; if not prosecuted by the woman within forty days; and subjecting the offender only to two years imprisonment, and a fine at the king's will. But in the 13 Edw. I. it was found necessary to make the offence of rape felony, by flat. Welfm. 2. cap. 34. And by 18 Eliz. cap. 7. it was made felony without benefit of clergy; as also the abominable wickedness of carnally knowing or abusing any woman-child, under the age of ten years; in which case the consent or non-consent is immaterial, as, by reason of her tender years, she is incapable of judgment and discretion. Sir Matthew Hale is indeed of opinion, that such prodigal actions committed on an infant under the age of twelve years, the age of female discretion by the common law, either with or without consent, amount to rape and felony, as well fines, as before the nativity of queen Elizabeth; but the law has in general been held only to extend to infants under ten. A male infant, under the age of fourteen years, is professed by law incapable of committing a rape; and, therefore, cannot be found guilty of it.

The civil law seems to suppute a prostitute incapable of any injuries of this kind; not allowing any punishment for violating the chastity of her who hath indeed no chastity at all, or at least hath no regard to it. But the law of England holds it to be felony to force even a concubine or harlot; because the woman may have forsworn that unlawful course of life.

As to the material facts requisite to be given in evidence and proved upon an indictment of rape, we shall here only observe, that the party ravished may give evidence upon oath, and is in law a competent witness; but the credibility of her testimony must be left to the jury, upon the circumstances of fact that concur in that testimony: e. g. if the witnesses be of good fame; if the presently discovered the offence and made search for the offender; if the party accused fled for it: these and the like are concurrence circumstances, which give greater probability to her evidence. But, on the other side, if the be of evil fame, and stands unsupported by others; if the concealed the injury for any considerable time after she had opportunity to complain; if the place, where the fact was alleged to be committed, was where it was possible she might have been heard, and the woman made no outcry; these and the like circumstances carry a strong, but not conclusive, presumption, that her testimony is false or feigned. Moreover, if the rape be charged to be committed on an infant under twelve years of age, she may still be a competent witness, if the hath sense and understanding to know the nature and obligation of an oath; and, even if she hath not, it is thought by Sir Matthew Hale that the ought to be heard, without oath, to give the court information; though that alone will not be sufficient to convict the offender. And, indeed, it is now settled, that infants of any age are to be heard; and if they have any idea of an oath, to be also sworn: it being found by experience, that infants of very tender years often give the clearest and truest testimony. Blackf. Com. book iv.

The civilians make another kind of rape, called subornatio, rape of subornation, or seduction; which is, when a person seduces or entices a maid to uncleanness, or even marriage, and that by gentle means; provided there be a considerable dilpary in age or condition between the parties. In this case, the father and mother intend their action reciprocally for the crimina raptus, or subornationis.

The French laws make no difference between the rape of violence and that of solicitation, or subornation; they make both capital. This kind of rape our laws call Rapeishment; which fee.

RAPe of the Forest, is a trespass committed in the forest by violence.

This is mentioned in the laws of Henry I. as one of the crimes cognizable alone by the king.

Rape is also a name given to the wood or flanks of the clusters of grapes, when dried, and freed from the fruit.

The rape is used in making vinegar, serving to heat and spicing the wine: but it is first put into a place to four itself, before it be cast into the vinegar vell; to which end, presently after the vintage, it is carefully put up in barrels, baskets, or in a willow box, otherwise it would heat itself and be spoilt. There is no other way of keeping rape hitherto discovered, but to fill the vessel, in which it is contained, with wine or vinegar.

Rape, Rapea, is also used for a part or division of a county; signifying as much as a hundred.

Though sometimes rape is taken for a division containing several hundreds. Thus Suffex is divided into six rapses, viz. those of Chichester, Arundel, Bramber, Lewes, Pevensey, and Hastings: every one of which, besides its hundreds, has a castle, a river, and forest belonging to it.

The like parts in other counties are called Rokings, Bloats, or waertakes.

Rape, in Botany. See NAPUS.

Rape, Broom. (See Orchanche.) It frequently grows to
to the roots of genista or broom, whence it is called *rapum genista*, or broom rape; it is also found among corn. The herb preferred, or its syrup, is said to be of excellent use in splenetic or hypochondriac distempers, and an ointment prepared of it with ivy’s fat, is good for hard and febrifugous tumours.

**Rape, Wild.** See MUSTARD.

**Rape, in Gardening,** the common name of a plant of the cabbage kind. The variety called the French turnip, or *Brassica rapax*, has been long cultivated upon the continent, and preferred to the common turnip as a culinary vegetable. And it has been lately noticed in the “Transactions of the Horticultural Society,” that it has been brought to the principal London markets for more than twelve years past by one person only, and fold chiefly to foreigners, though, when once fully known, it will be found a very useful and acceptable root in most families, as being more delicate in its flavour than the common turnip. It is used in much the same manner. It enriches soups, and there is not any necessity for cutting away the outer skin or rind, but only to scrape it, as it is a great deal thinner than that of the turnip. When stewed with gravy it forms an excellent dish, and being white and shaped like the carrot, when laid alternately with those on a dish, they become very ornamental. The French drefs them somwhat in this manner.

The roots are to be washed quite clean by means of a brush; then scraped, cutting a thin slice away from the top and bottom parts, so as to make them all of equal lengths: after which boil them in water, with a little salt, until they are tender; then put them into a stew-pan, with a gill of sweet gravy, two spoonsful of lemon pickle, one of mushroom ketchup, a little mace, and salt, letting them simmer, but by no means boil, for a quarter of an hour; afterwards thicken the gravy with flour and butter, serving the whole up quite hot. Some add a few spoonsful of cream mixed with yolk of egg to this, just before dishing up; and others dress them in a similar manner to theabove, iced rather thinly, with Madeira, or other wines, after they have been fried to a brownish colour. See Brassica.

**Rape, in Agriculture,** the name of a plant much cultivated for its seed, and also as a green food for cattle and sheep. The methods of culture and management that are necessary in rearing crops of this sort, have been already described and explained. (See Cole.) It may, however, be here necessary to detail a few of the experiments that were made under the direction of the Dublin Society, by Mr. Whyn Baker, about the years 1769 and 1770, as they tend to throw additional light on the nature of the plant, as well as its cultivation, though the soil was not the most suitable for it. It was a shallow soil, of a strong adhesive nature when wet, and when perfectly dry, in lumps, almost impregnable; but between wet and dry, reducible. It lies upon a bed of lime-flour quarry, and has a natural declivity to the north-west; naturally very poor, and, he believes, never received any manure until he dressed it. Three acres of this land were, in 1768, under potatoes, in the ordinary method of the country, in seven-feet beds, and four-feet trenches. In 1769 they were under drilled turnips.

The frost, snow, hail, and rain which they had this year in the months of March and April, rendered it impossible to get the ground in any tolerable condition for the rape-feed before the 28th day of April. On that day twenty broad hills were sown, with twelve ounces of rape-feed to each hill or ridge. He intended to have sown it earlier; but the event will shew, that, as it was, he sowed it too early, at least upon this ground.

It was slow in coming up, and made but a poor figure until July. After which it shot forward; but instead of affording a plentiful mowing crop for the purpose of foddering cattle, it soon began to run up very fast; broke out into branches, with few and small leaves, like rape in blossom from the autumn sowing, but with strong branches and few leaves; and, in a short time after, began to grow hard, pipey, and the feed to form.

It was just in September he began to sow it for cattle, and they ate it with great celerity; but every day it became worse, by growing harder; insomuch, that before it was gathered, there was very great waste, as to the object of fodder, but it wonderfully raised the dung-hill, which, in his mind, is of the first moment to the farmer: for if he has manure in plenty, and dipposies of it judiciously, there is hardly any thing he need to fear, except climate.

It was pretty far in October before all his rape was cut, (and the seed coming forward very fast,) although it was brought home in great perfection. It was so strong, that the mowing of it could not be accomplished with a common scythe; it would have broken an hundred; but he had by him a short scythe scythe, with a thick back, intended to mow bushes and other rubbish; with this instrument he got it mowed, but not so close to the ground as he wished, it being next to impossible to mow such strong plants as these were close to the ground; and he became the less formidable about it, as from the strength of the rape flumps and roots, and the weeds which were upon the ground, owing to the rape shooting up in tall stems, he gave up his intention of mowing the ground with wheat, as was originally intended. Hence he concludes, that the rape was found much too early.

On the 16th of July he transplanted some of this rape in rows upon ridges four feet wide; these plants flourished much better than the former, and were at least four times the size of any of those left in the ground where they were sown. Nevertheless, these also ran to feed; but the cold nights coming on prevented their forming their feed like the former. They were vastly more fappy, and much better food for cattle.

On the 24th of July, he dressed rape-feed upon the same ground.

**No. 1.** Six ridges four feet wide, and thirty-two perches long in single rows.

**No. 2.** Six ridges the fame length and breadth, in double rows, ten inches asunder.

It is observed, that the double and single rows were dressed alternately on the same ground, on the 18th day of July.

**No. 3.** Six ridges four feet wide, and thirty-two perches long, dressed in single rows.

**No. 4.** Six ridges the same length and breadth, in double rows, ten inches asunder.

He remarks, that these were sown in alternate rows, on the same ground, on the 24th of July. And that the several rows were thinned the latter end of August, and twice horse-lodged during the summer. On the third of April 1771, he had a row of each of these cut and weighed, and the produce was as follows:

RAP

On the whole, it is stated, that the last sowing in July afforded considerably greater produce than the first, for the plainest reason, that the earlier we sow this seed, the sooner it runs; and consequently affords the less produce for the purpose of foddering cattle in the yards for making dung, and seems to account very strongly for the fate of the first experiment.

And the double rows produced uniformly more than the single rows; and indicate that the double are to be preferred in drilling rape for foddering cattle.

The following trials are on sowing rape-feed broad-cast. On the 24th of July two acres were sown broad-cast, with ten pounds of seed per acre, in the same field where the other experiments were carried on; but the soil not so flabby by a good deal, has abundantly fewer loose stones in it, and is very flillary, and poor, to an incapability of producing anything to profit, without great assistance of manure.

In July he manured it with the dung of his yard, consisting of that of horned cattle, horses, and swine. The dressing was indeed very high; about two smart one-horse cart-loads to a perch. He having ever found that one acre, highly improved, is much more valuable than five imperfectly handled, was the reason why he gave this poor piece to liberal a dressing.

The rape came up but slowly for a time, as he finds to be the nature of the plant, but at length it flourished, and flourished away: but in winter it met with a fate which he was not aware of, nor did he expect. The wood-pigeons lay upon it prodigiously, and did it great damage. Some plants he observed in the frost to appear as if they had been fingered; whether that was owing to the wounds given by the birds, and thereby giving the frost the greater force, or whether it was owing entirely to the severity of the frost, is not in his power to determine. However, very early in the spring this rape flourished, and as the days lengthened the visits of the pigeons were less frequent, until they totally left it.

From this rape breaking out into blossom sooner than he expected, he is inclined to believe that the 24th of July is too early to sow it for the purpose of foddering cattle in the yard.

However, early in April he began to sow this rape for the horned cattle, such as cows, plough bullocks, young cattle, calves, and swine. They all ate it with the greatest eagerness, and were foddered with it every evening, until the 19th of May inclusive, and wheat straw in a morning, five four calves of the preceding year; and they were foddered twice a day with rape, and had straw before them also, and threw upon it vastly better than the other cattle; for no other reason, he believes, than because they were allowed more than the others: in short, they were in such order, that he dares believe the butchers would have been glad to have had them for killing.

He observes, that he need not tell the farmer how necessary it is to be frugal of provender in an arid dry spring, as the last was, when we were like to be hard run with forty head of cattle, many of which he should actually have been obliged to sell at so improper a feason, had he not been poissed of these two acres of rape. He adds, that there is yet another circumstance which renders this a truly valuable fodder. The milk of the cows increased prodigiously; and the milk and butter were as good, sweet, and well-flavoured, he thinks, in every particular, as ever he tasted in June. Even the cream for the tea appeared to be perfectly free from any foreign flavour. The cows got hay every day, in the same manner as he has in former years mentioned them to have, when feeding upon cabbages.

The simplicity of the culture for rape, for the purpose of feeding cattle, he cannot but think a particular recommendation to the farmer, and the cheapness of the feed in purchase, or the cafe with which he may raise it, are objects which cannot fail, he thinks, of being persuasive to him. And all persons, who have annexed to their farms any bog, or other waste ground, the improvement of which can be executed by burning, might surely raise such quantities of rape for the purpose of mowing pasture, as would enable them to keep almost any number of cattle; by which they would not only be bringing in the waste land, but making that the foundation of improvement to their found land, by the immense quantities of dung they might raise by this means from the waste land. Here the advantage to the cultivator would be double.

On the first day of May he had four perches of this rape measured out for weighing. It was mowed, immediately drawn home, and weighed. The four perches afforded seven hundred and two quarters: multiplying this by forty, shews the acreable produce to be fifteen tons. The quantity indeed but small. However, the season in which it is to be had renders it more than ordinarily valuable, and, he thinks, bids fair to make it an object of husbandry, as a pasture for cattle.

This year, 1770, Mr. Baker ploughed up fix acres of wheat stubble, as soon as the wheat came off, harrowed it down the 12th, 13th, 14th, and 15th of September, then sowed rape-feed over the whole field, and gave it a light bush harrowing. The rape came up very thin, and made so poor an appearance in the spring, that he ploughed up the field, and sowed spring corn. This is a strong indication that but little is to be expected from sowing rape upon wheat stubble; because after the wheat comes off it seems to be too late in the year to sow rape. But something may be charged, as he observes, to the natural moisture of the soil. See Cole.

The following is the recapitulation of his experiments on rape, as pasture for cattle.

Rape is a great deal cultivated in some districts in the county of Essex for the feed. The system is very profitable, but this sort of crop is found to draw or exhaust the land a good deal. It is thought by some to prepare well for wheat, especially when fed off upon the land. In some places they, however, consider it more beneficial to till, after this crop has been fedded for spring corn, than to put in wheat, which, however, is still the most common practice. Clover would certainly be better than either method.

In other places they conceive that feeding rape is much on the decline, from the general experience, that it leaves the soil prepared land in an unfavourable state for oats and clover,
RAP
clover, and is consequently prejudicial to the next succeeding winter crop. Other districts think very differently on this point. In feeding the crop, the produce is here considered to be in general from twenty-nine to thirty-four bushels the acre. In the greatest crops and best seasons, in particular parts it is supposed to rise even so high as five and six quarters the acre.

In Berkshire this fort of crop is not so much cultivated as it should be, as it will succeed well on soil where turnips will not, and with equally beneficial effects to the future crops, when fed off the ground. When employed it is usually sown and managed so as to come into a high state of luxuriance in the early spring months, when sheep feed is mostly scarce. It is grown by some to supply the deficiency, and found remarkably useful, one acre of it affording more feed than two of turnips.

This fort of crop is still less grown in Oxfordshire, though occasionally had recourse to, especially on the rich red land about Banbury. Some few it in mixture with the tankard turnip feed, for the purpose of weaning lambs upon; they begin with the rape, and it teaches them to eat the turnips: it is found to be a very good food for this fort of flock.

In the county of Suffolk, the South Down sheep farmers hold it in great estimation, sowing it either alone or in mixture with tares as a food for their sheep; very rarely for the purpose of feeding. The ewes and lambs are wattled upon it in the spring, and it is very generally allowed to be more efficacious, and highly nutritious to the young lambs. Some, at the lambing season, hardly allow their ewes any other food but this, as the rape is found to produce a larger supply of milk than turnips; which it is supposed, has the effect of extending the udder, without affording any considerable flow of milk. This crop is conjectured, however, in some cases, to have the effect of causing the flapping of the lambs, where the ewes are fed upon it. But such an effect is very improbable to arise in this way; other causes may have been overlooked. In some cases on Down land ray-grafs is sown with the rape for sheep feed, one gallon of rape-feed and two of ray-grafs to the acre. The rape is first fed off; and after that the ray-grafs ripes and affords a bite for the spring seafon. The rape crop is usually put in about June, or the following month, one gallon to the acre. When folded off, a rood and a half is a sufficient daily consumption for a flock of fix hundred sheep, or rather more.

As it has been found in the improving of peat boggy morally lands, that what is principally wanted is a crop which can be sown and reaped in thesummer months; and which may require neither labour nor attendance during the moist seafons of autumn, winter, and spring; the writer of the "Treatise on Landed Property" has suggested that fortunately, such a crop is natural to, and has long been inured to the climate of this island, as one of the most profitable in the agriculture of it; and that this is rape: which is not only sown, but reaped, in the very height of summer; and which is known to delight in a foil of this nature. It has, however, only lately been found capable of being raised with advantage on crude moyst ground, as a first crop after draining, from some recent trials made in the north, after the above operation, levelling, paring and burning, and turning the ashes in. The result of which was, though the crop was too late in being put in, and the land laid in an improper manner, such as to prove clearly that rape-feed may be raised with profit as a first crop on drained moyst soils. And it is thought highly probable that many extensive tracts of land, which now lie entirely waste, and as nuisances in their neightbourhoods, may through this means be improved with immense profit to their proprietors. The experiment may be tried at a small expence. The cost of the labour and feed required for a sufficient trial are incomconsiderable. The proof, it is supposed, is not whether rape will thrive as herbage, but whether it will mature its feed, on the given foil, in the given situation.

After being recompensed for the previous expences, in one or more rape crops, as there is here no danger of the exhaustion of the foil.—of impoverishing, perhaps, ten feet depth of vegetable mould, it remains to lay the foundation of more permanent profits, which is to be done by sowing grasses feeds either with or over the rape crop, or by light cautious jockeying after removing the flanks, as may be necessary, until there is a firmness of surface and a tinctura for mixed cultivation, which may be much hastened by the use of heavy calcareous and earthy furnaces in any time during the process of improvement.

Rape Cake, the refuse or cake remaining after the oil has been expressed from rape-feed. It is said to be useful as a manure. See MANURE.

This variety is found by chemical trials to contain a large quantity of mucilage, some albuminous matter, and a small quantity of oil, which should be kept as dry as possible before it is applied to the foil, and be employed in that way while it is in a fresh state. It is successfully applied in several ways and intentions, and affords an excellent dressing for turnips. See the next article.

Rape Dust, the small reduced parts of the dried refuse of rape-feed, or the rape cake, after the oil has been obtained from it. This variety has been found useful as a top-dressing for crops of different kinds.

The rape cake, when reduced into powder or dust by means of a machine, has been extensively used in Norfolk; and when for turnip crops, it has been the custom to sow it some weeks before the feed of that root is put into the ground. In the practice of Mr. Coke of that district, it has, however, been found, that by having it brought into a fine powder it may be drilled from the same machine, at the same time with the turnip feed; and that, by thus delivering the manure and the seed from the same pipes and hares of the drill machine, a ton of dust does fix acres in the place of three. See TURNIP.

In Lancashire some farmers use it with great advantage as a manure for potatoes, putting it in with the fets in the proportion of about thirty-two bushels to the statute acre; but if the ground were well prepared, and the dust carefully deposited for the reception of the fets, it is supposd, a much smaller quantity would be sufficient. It produces much luxuriance in the crops, and a very fine produce.

Rape OIl, the oil obtained by means of expression from the seeds of this plant, in mills constructed for the purpose. The refuse oily substance of this kind may be employed as manure in mixture with rich earthy matters, with great advantage, wherever it can be procured in any quantity at a reasonable price.

RAPEL, in Geography, a river of Chili, which runs into the Pacific ocean, S. lat. 34° 8'.—Alfo, a town of Chili, on the beforementioned river; 70 miles S. of Valparayo.

RAPERLAH, a town of Hindooolfan, in the Carnatic; 13 miles N.E. of Oogole.

RAPHA, in Anatomy. See RAPHE.

RAPHAEL, one of the seven archangels, who are said to be continually before the throne of God, and ready to perform his commands. We have no such name in the Old
RAPHAEL.

or New Testament; but his history occurs in the book of Tobit, c. xii.

If the story of Tobit be true, it is not improbable that the angels, both good and bad, whose names do not appear to have been known before the Babylonish captivity, are figural protecting agencies of divine providence, to dispose events so as to produce a happy issue.

RAPHAEL SANZIO, DA URBINO, in Biography, during whole life, and by the exertion of his talents, in conjunction with those of Leonardo da Vinci, Titian, Michael Angelo, and some few others, the art of painting reached its acme in modern times, was born in the city of Urbino, on the morning of Good Friday, in the year 1483. He was descended from a respectable family, and many of his ancestors had been painters; as was his father Giovanni Sanzio, whose talents, however, did not elevate him to the first rank. He cultivated with care the inclination which his son Raphael exhibited, at an early age, for painting; and was soon repaid by the affiance he acquired from him, in several of the pictures he was employed to paint in his native city of Urbino. But finding that the taste of Raphael merited more filial guidance than he was able to give it, he placed him under the tuition of Corradini, better known by the name of Carneval, for a short time, till he could be received as a pupil by Pietro Perugino, at Perugia.

This master was then in very high esteem, though his style was dry and meagre, in comparison with that of Masaccio, and others of the Florentine school. It is not surprising that Raphael, endowed as he was by nature, and trained as he had been in art, should soon become the rival, rather than the pupil, of such an artist. Accordingly we find, that his aptitude for the practice of art enabled him quickly to acquire his master's manner, and that in so perfect a degree, that connoisseurs were puzzled in their judgments upon the works which proceeded from Perugino's studio; and ordinary observers completely deceived. Vafari speaks of an Assumption of the Virgin, crowned by her Son, and the twelve apostles below, round her tomb, contemplating the celestial glories; with three small pictures in the same frame below it, of the Annunciation, the Adoration of the Magi, and Simon embracing the Saviour, painted at this period by Raphael, as being wrought with extreme beauty, and precisely like the work of Perugino.

We have to lament that we are left ignorant of the time when Raphael went as a pupil to Pietro, how long he remained with him, or when he left him, or rather was left by him; as that master returned to Florence, to finish some pictures he had begun there some time before. He must certainly have been very young, from the number of pictures which he subsequently executed, previous to his going to Rome in his 25th year, and probably not more than 16 or 17, when he acquired his liberty by the departure of Perugino.

From Perugia he went to Citta di Castello, where he painted a St. Nicola crowned by the Virgin and St. Augulfina, for the church of St. Augulfina; and for that of St. Dominico, a picture of the Crucifixion of Christ, accompanied by angels, the Virgin, St. John, &c.; which would certainly have been considered as Perugino's, if Raphael had not felt his name to them. But he was considered to have much surpassed him in another work, representing the marriage of the Virgin and St. Francesco, for the church of St. Francesco, in the same city. He acquired by these productions a great and deserved extent of fame, and thus early entered with success that course, which conducted him to the highest pinnacle of renown as an artist.

Attached to his person by friendship, and attracted by his skill as a designer, Pinturicchio, then employed by pope Pius II. to adorn the library of the Duomo at Sienna, sought the affiance of Raphael, and engaged him to compose designs for his work. This he undertook, but proceeded only to the preparation of some of the cartoons, when his ambition and curiosity were stimulated, and his work interrupted by the renown spread through the country of the cartoons painted by those great rivals, Leonardo da Vinci and M. Angelo, for the council-hall at Florence. He immediately determined, in conjunction with almost all his brother artists of the day, upon going to see and form his judgment upon them for himself; and consequently left his engagement with Pinturicchio, and proceeded to Florence.

In this city he found many attractive beauties, both of nature and art, that he resolved to fix his residence there for some time. His agreeable person and manners, combined with the extraordinary talents he had manifested, infused him with friendship: and he became intimate with several artists of celebrity, among whom were Ghirlandajo, St. Gallo, and Taddeo Taddei; the latter of them, a learned man, and friend of cardinal Bembo, took the youthful painter to his house and table, and thus afforded him the best introduction to the world, while he pursued his more immediate studies. This kindled the gentle heart of Raphael accepted with grateful emotion; and as he painted several pictures during his residence in that city, he prefented two of them to Taddei. One of these pictures, a Madonna with the Child, and St. John bringing a little bird to him, the heirs of Taddei fold to the archduke Ferdinand Charles of Austria at a great price: the other is lost sight of. He also presented a picture to his friend Lorenzo Nati, which afterwards found a place in the Medicean gallery, and a duplicate in that of the monastery of Valomirofa.

From Florence Raphael was recalled to Urbino, by the death of both his father and mother; and there, when he had arranged his private affairs, he was engaged by Grinobaldo de Montefeltro, and several others, to paint religious subjects for the altars of their chapels; and among those he painted at this time, were the two little St. Georges, now in the gallery of the Louvre. These commissioned works he executed with great taste and delicacy; and Vafari, who enumerates them, more particularly speaks of one of Christ praying in the garden, painted for Francesco Maria, duke of Urbino, as being finished with all the neatness of a miniature. What is become of most of these pictures, it is not easy to ascertain; but it is a curious fact, that not one of them remains at this time to adorn the native city of this great artist.

Thence he returned to Perugia, and painted several pictures. For the church of the Frati de Servi, one of the Virgin, with St. John Baptist, and St. Nicholas. For that of St. Stevens, in the chapel of our Lady, he painted in fresco a picture of Christ in glory, with God the Father, surrounded by angels and six saints, three on each side. Upon this picture he wrote his name in large letters of gold, and very conspicuously, as if he himself were pleased with the performance of it. He also painted here a picture for the nuns of St. Antonio da Padua, of our Lady with the Infant upon her lap clothed, and near her St. Peter, St. Paul, Sta. Cecilia, and Sta. Catherine. The air and attire of the two female heads were regarded as the most tasteful work of the time, wrought with the greatest degree of beauty and grace. Above the picture, in a medallion, was represented
represented the Almighty Father; and at the foot of it, in three compartments, were the scenes of our Lord's sufferings, viz. his agony in the garden, carrying his croos, and dead upon the lap of the Virgin. It is not known what is become of the centre picture, or the uppermost compartment; the lower ones formed a part of the Orleans collection. The execution of these works was performed in a style much improved upon that of Perugino; with more breadth, more loftiness, and more freedom and variety of action; proving that he had not ill spent the time he had devoted at Florence to the study of the works of other painters. Hence we may date the commencement of what is termed his second manner, from his first visit to that city.

Soon after he had produced these works at Perugia, that zeal for cultivation, which always accompanies true genius, led him to determine upon again visiting Florence, at that time the emporium of science and of art. Though the native strength and purity of his mind were such as to conduct him, under favourable circumstances, to his future prominent station; yet he does not appear to have been so extraordinary and original an inventor in the art itself as M. Angelo, or his great predecessor and rival, Lionardo da Vinci. He knew how to take a hint of what was offered to his view, and to cultivate and improve it to his purpose; but it yet remains a problem, whether Raphael, alone, and without the leading aid of those great and original artists, would have ever seen the sublime of painting. His power may rather be said to have conferred in ability to employ the materials furnished by their invention, viz. the style of Michael Angelo, in form; and of Lionardo da Vinci, in chiaro-tenuto and colour; in beautiful conceptions, illustrative of the character and passions of man; and in an admirable feleotion of subject, and mode of conveying it.

He himself appears to have been conscious of this; for we find him in the midst of honourable employment, leaving the prosecution of it, to study and improve himself by a constant observation of the works of other renowned artists, and again repairing to Florence, where alone he could find the true source of found cultivation, and in which he made so good use of his time, as to fit him in great measure for the glorious field of exertion which awaited him.

On his return to the renowned abode of those great artists, from whose works he sought improvement, he had a letter of recommendation and introduction from the dukes of Urbino to Pietro Soderini Gonfaloniere of the city; and was thus introduced to the best circle of improvement and information.

It would have been highly gratifying to have been enabled to trace the steps of a man so distinghu hed in the art, from the earliest commencement of his studies; but the neglect of dates, by his historians, counteracts every wish to follow them more closely; and the record of facts leaves us only the means of conjecture. That he began to paint original pictures very soon after he was placed with Perugino is evident, and he must then have been very young, for it is on record, that the pictures by Pinturicchio, for which he made the cartoons at Siena, were completed in 1503, at which time he was 20. If we allow, as we reasonably may, two years for their execution, it will place his first visit to Florence in 1501, at the age of 18; and it certainly cannot have been far from that period. In every part of his life, modesty, ingenuity, and the ardour of a mind entirely devoted to his art, characterized his conduct. His industry and ingenuity seem to have kept equal pace; and the rapidity and certainty with which he must have painted, to produce so many pictures in so short a space of time as he lived, are not the least extraordinary part of his history.

On this, his second abode at Florence, he studied deeply the works of Mafaccio, and the cartoons of Angelo and Da Vinci; and attached himself in friendship to Baccio della Porta, better known by the name of Fra. Bartolommeo; than whom no one was better qualified to direct him rightly in whatever was grand and dignified, and from whole judicious information in the art of calling draperies and of colouring, Raphael evidently improved exceedingly; while he had the pleasure, in return, of communicating to his friend the principles of perspective. Yet notwithstanding these helps, he did not entirely free himself from the formal and dry manner of his master, though he painted affably both in portrait and history. In the former he produced the portraits of Angelo Doni and his lady Maddalena Strozzi; and in the latter he painted for Dominico Caneggianni, a Madonna, with the Infant playing with St. John brought by Elizabeth, who regards St. Joseph as he flings near, leaning both his hands upon a stick, and inclining his head towards her. This picture appears to have been re-touched, or possibly completed only in 1516, as the name of Raphael, with that date, in letters of gold, is written upon the drapery of the Virgin. He also made a cartoon during his residence in Florence for a picture which he had previously engaged to paint for the Baglioni family at Perugia, and left the city to go and paint it in the church of St. Francesco in that place. The subject of it was our Saviour carried to the sepulchre, accompanied by the Virgin, St. John, &c.; and it was exceedingly admired for the beauty and expression of the figures, and the skill and perfection of the draperies. This picture was removed from Perugia by pope Paul V., and a copy, by Cefare d'Arpino, placed in its stead: it afterwards found a station in the Borghese palace at Rome.

When Raphael had completed this work, he returned to renew his studies at Florence, and was employed by the family of Dei, to paint a picture for their altar in Santo Spirito, which he began, and conducted through the preparatory parts; and in the mean time painted another for the city of Siena, of the Madonna in an open country, with the Child standing by her, and St. John kneeling before him, but was interrupted, in its execution, by a summons from pope Julius II. to Rome, and left it in the hands of his friend Ghirlandaio, to finish a piece of blue drapery which it wanted. This picture was afterwards sold to Francis, king of France, and is at present in the French collection, known by the name of the Belle Jardiniere. The unfinished sketch of the picture begun for the Dei family, was bought, after the death of Raphael, from his heirs, by Baldufino Turini, and placed by him, in its original state, at the altar of his country church; it afterwards came into possession of the house of Buonvicini di Pecchi, and was sold, by that family, to the grand duke Ferdinand, who, on removing it, placed a copy by Carlo Sacconi in its stead. This was done at night, and with the utmost secrecy, for fear of a disturbance among the populace, by whom it was highly prized.

Raphael was indebted for the high patronage of the pope, which placed him in the proper sphere for the exercise of talents such as he peffessed, to the friendship of his relation Bramante d'Urbino the architect; and never was recommendation better supported by ability. Upon his arrival in Rome, in 1508, he was received with great courtesy by Julius, and the Camera della Segnatura, in the Vatican, assigned to him. He immediately began the preparation for his first picture, which was the School of Theology, better known by the name of the Dispute of the Sacrament, and in observing which, it is worthy
worthy of remark how his mind enlarged, in regard to style in the art, as he became accustomed to consider largely of his work; and according to the field of employment which he found before him. The difference in style between one part of the picture, and that of the other, evidently points out where he began it; viz. on the right of the upper part, where the remains of the school of Perugino appears, and is spread through the centre, where the glory which surrounds our Saviour is represented in the Gothic manner, by rays of gold. As he proceeded, his style enlarged, and the lower part of the picture exhibits an immense improvement, and is almost equal to any of his subsequent productions.

In the same room are the pictures of the School of Athens, the Parnassus, painted in 1512, (where, surrounding Apollo and the Muses, he has introduced portraits of the great poets, both of antiquity and of his own time,) and the Jurisprudence, comprising two subjects, one of the emperor Julian delivering the digest of his code of laws to Tribonian, and another of pope Gregory IV. giving the decretal to a member of the conclave. Over each of these subjects, respectively, are painted circular ones of single figures, representing Theology, Philosophy, Poetry, and Justice.

When pope Julius saw the superior taste and talent with which Raphael produced the former of these works, he immediately ordered the whole of the Stanze, or chambers, which it was intended to decorate, to be entrusted to him; and all that had previously been done by Perugino, Pietro del Borgo, II. Sodoma, and Bramante di Milano, to be removed. But of this order Raphael made only a partial use; preferring entire the work of his firft matter, and, partially, the ornamental labours of II. Sodoma.

While he was engaged upon these great works, he was not altogether indifferent to the more agreeable exercise of the pencil, and he painted for the church of the Augustines, the pictures of the prophet Isaiah, and the Sibyls who are supposed to have predicted the coming of Christ. He also painted the portrait of his great patron, Julius, now in the Louvre, and several smaller cafe pictures of Madonnas, and other religious subjects. By these labours he acquired the renown they so well merited, and his manners appear to have been in perfect accordance with the beauties of his mind. His person also was handsome, and he was beloved, esteemed, and admired. Yet he continued to study, and to improve his talents, employing personæ to collect specimens and make drawings from Grecian remains. Full of taste and feeling, he spared no pains to perfect his powers by a thorough knowledge of all that had been done in art, both ancient and modern.

In consequence, however, the fact, related by Vasari, may be doubted, of his being admitted, while Michael Angelo was absent, to see the work of that great artist in the chapel of Sixtus IV.; the taste in which he wrought became aggranized, and similar to that introduced by M. Angelo. About this time he painted the Galatea for Agostini Gligi, and the Madonna di Foligno, at the desire of Sigimundo Conti, secretary of pope Julius II., for the great altar of the church at Araceli, and which is now at the Louvre.

In another chamber of the Vatican he painted four other large pictures, the subjects of which are the miracle of Bolsena, when the officiating priest, who doubted of the real presence in the Eucharist, is offering up the host, and perceiving, with allomiment, that it dittils drops of blood; the release of St. Peter from prison; the Heloudorus; and Attila arraigned, in his journey to Rome, by a vision of St. Peter and St. Paul; these were completed in 1512, 13, and 14.

In these pictures his great improvement in colouring and style is most evident, and he continued to carry it still further into practice in another room, for which also he had composed four other subjects, known as the Incendio del Borgo; the coronation of Charlemagne by Leo III.; the fame pope defending his conduct to the army pope; and the defeat of the Saracens at the port of Olija.

While Raphael was engaged on the Heloudorus, his first great patron, Julius II., died; but fortunately for the arts, if not for the tiara, he was succeeded by another, Leo X., who was even more attached to them, and more fond of the renown arising from the cultivation of whatever adorns society. By him, therefore, Raphael was ardently encouraged to proceed with his labours, and he continued to make designs for other apartments, particularly for the great hall of Constanitine, as it is now called; but he did not live to execute them. The Incendio del Borgo was the last upon which he himself wrought; the rest were completed by Julio Romano. He was also employed by Leo to make the cartoons now at Hampton Court, as exemplars for works in tapestry, to be executed in Flanders, and which were completed at the expense of 100,000 crowns. Fortunately for us the originals were never returned to Rome, and were purchased afterwards by Charles I.

Upon the death of Bramante, in 1514, the superintendence of the architectural concerns of the Vatican was entrusted to Raphael, who had already exhibited his knowledge and taste in that art, by the introduction he had made of it in his pictures. He invented and began a palace for himself, and made several designs for others.

Notwithstanding the immense application necessary for the invention and completion of these important labours, together with the designs he composed for the ornamental parts, and the scriptural subjects on the ceilings and the covings of the loggia and Stanze of the Vatican, he found time to execute in fresco the designs which adorn the palace of Agostino Giigi; the capital portrait of his great friend Leo X., with the cardinals de Medici and Roffi, now in the Louvre; the St. Michael, and the vision of Ezekiel, both in the famous grand depôt; a Madonna, Child, and St. Anne, for Florence; and a large picture of Christ bearing his Cross, for the monastery of St. Maria della Spalma, at Palermo. Of this picture it is reported, that being lent on shipboard to go to Sicily, the vessel was beaten from its course by a tempest, and the mariners lost; when it drifted to Genoa, and of course its preservation was attributed to the divine influence of this great work. The Genoese chuse also to suppose that the hand of God had thus pointed out their city as the proper place for its residence; and would not relinquish it for a length of time, till the papal influence interfered, when it was configned to its original definition. He also painted the picture of St. John, which adorned the Orleau collection; and last of all, the Transfiguration; which indeed he had not quite finished when the unrelenting hand of death sent a period to his labours, and deprived the world of further benefit from his talents, when he had only attained an age at which most other men are but beginning to be useful.

The immediate cause of his death is allowed to have been brought on by too great an indulgence in gallantry, and, Vasari adds, by mismanagement of his physicians, who bled him when they ought to have administered restoratives. On his death bed he made his will, leaving his favourite pupils, Julio Romano and II. Fattore, his heirs, and ordering his burial
RAP

burial to take place in the Pantheon (the church of Santa Maria Rotunda), where a monument still remains to his honour. He died on the same day of the year on which he was born, Good Friday, in 1520, at the age of 37, deeply lamented by all who knew his value. His body lay for a while in state, in one of the rooms wherein he had displayed the powers of his mind, and he was honoured by a public funeral; his last produce, the Transfiguration, being carried before him in the procession; and, that Rome might not be deprived of so noble a memorial of this extraordinary man, it was placed by the cardinal de Medici in the church of St. Pietro a Montorio, instead of being sent to France, as was originally intended.

Mr. Fufeli, in his edition of Pilkington, has given so discriminating and just an idea of the peculiar excellencies of Raphael, that we shall conclude our history of him by quoting it. "The general opinion has placed Raphael at the head of his art, not because he possessed a decided superiority over every other painter in every branch, but because no other artist ever arrived at unity with his own peculiar excellence all the other parts of the art in an equal degree with him."

"The drama, or in other words the representation of character in conflict with passion, was his sphere; to represent this, his invention in the choice of the moment, his composition in the arrangement of his actors, and his expression in the delineation of their emotions, were, and are, and perhaps will be unrivalled. And to this he added a style of design dictated by the subject itself, a colour suited to the subject, all the grace which propriety permitted, or sentiment suggested, and as much chiaro-fcuro as was compatible with his supreme defile of pertinacity and evidence. It is therefore only when he forgoes the drama, to make excursions into the pure epic or sublime, that his forms become inadequate, and were inferior to those of M. Angelo; it is only in subjects where colour from a vehicle becomes the ruling principle, that he is excelled by Titian; he yields to Correggio only in that grace and that chiaro-fcuro which is the minifter of propriety and sentiment, than its charming abufe, or voluptuous excess; and which facribes to the eye what was claimed in vain by the mind."

"Michael Angelo appears to have had no infancy; if he had, we are not acquainted with it; his earliest works equal in principle and elements of style the vigorous offsprings of his virility: Raphael we fee in his cradle, we hear him hammer; but propriety rocked the cradle, and character formed his lips. Even the trammels of Pietro Perugino, dry and servile in his style of design, formal and gothic in his composition, he traced what was essential, and separated it from what was accidental, in figure and subject. The works of Lionardo, and the cartoon of Piola, invigorated his eye, but it was the antique that completed the sylen which he had begun to establish on nature. From the antique he learned discrimination and propriety of form. He found that in the construction of the body, the articulation of the bones was the true cause of grace and grace in the action of the limbs, and that the knowledge of this was the true cause of the superiority of the ancients. He discovered that certain features were fitt for certain expressions, and peculiar to certain characters: that such a head, such hands, and such feet, are the flamen or the growth of such a body, and on phrynognosy established uniformity of parts. When he designed, his attention was immediately directed to the primary intention and motive of his figure, next to its general measure, then to the bones and their articulation, from them to the principal muscles of those eminently wanted, to their attendant nerves, and at last to the more or less essential

RAP

minute; but the character part of the subject is infallibly the characteristic part of his design, whether it be a rapid sketch, or a more finished drawing. The strokes of his pen or pencil themselves are characteristic: they follow the direction and texture of the part; flesh in their rounding, tendons in straight, bones in angular lines.

"Such was the felicity and propriety of Raphael, when employed in the dramatic evolutions of character! both suffered when he attempted to abstract the forms of sublimity and beauty; the painter of humanity, not often wielded with successfully super-human weapons. His gods never rose above prophetic or patriarchal forms; if the finger of Michael Angelo impressed the divine countenance oftener with human than with divinity, the gods of Raphael are sometimes too feeble or mild, like him who speaks to Jacob, in a ceiling of the Vatican; or too violent, like him who separates light from darkness, in the loggia of the same place. But though, to speak with things, he was chiefly made to walk with dignity on earth, he feared above it in the conception of Chrift on Tabor, and still more in the frown of the angelic countenance which withdraws the strength of Heliodorus.

"Of ideal female beauty, though himself, in his letter to count Calvin the, tells us, that from its scarcity in life, he made attempts to reach it by an idea formed in his own mind, he certainly wanted that standard which guided him in character: his deities and mythologic females are no more than aggravations of the generic forms of Michael Angelo. When the drama inspired Raphael, his women became definitions of grace and paths at once. Such is the exquisite line and turn of the half-averted kneeling female with two children, among the spectators of the punishment inflicted on Heliodorus; her attitude, the turn of her neck, supplies all face, and intimation more than he ever expressed by features."

RAPHAEL in Geography, a fertile and healthy district, being the well-ermenoff in the Spanish part of St. Domingo. Its northern boundary is found in part of the French parish Gonfaves. The air round St. Raphael is very fabulous, but the town, which is in a hollow, is very hot; to leagues S. of Cape Francois.

RAPHAEL, St. Cape, lies at the S. end of St. Domingo, and is the S.E. limit of Samana bay.

RAPHAEL, in Ancient Geography, a city of Syria, between which and Apia, or Aras, a city of Judea belonging to the kingdom of Agrippa, the Sambatic river flowed. Joseph. de Bell. i. vii. c. 24. Raphane is, perhaps, the Arpal of scripture. 2 Kings, xviii. 34. xix. 13. II. x. 9. xxxvi. 19. xxxvii. 13. Jerem. xxix. 23.

RAPHANIA, in Medical, an appellation given by Linnaeus, and afterwards by Dr. Cullen and others, to a fever and fatal disease, which has been desribed as epidemic in Sweden at particular feasons, and imputed to the use of the raphanus raphanifrum of Linnaeus as food.

It is not necessary to describe the symptoms of this disease in this place; since it is, in fact, the fame malady which has been epidemic in various other countries of Europe, during feasons of scarcity, and has been attributed to various other species of unwholesome grain, but more especially to diseased rye, afflicted with the ergot, to the lolium temulentum, to charlock, &c. We have already entered at great length into the history of the symptoms and imputed causes of this formidable malady, which has been more commonly denominated ergot, from one of its supposed sources. (See ERGOT.) We have endeavoured also to shew, that it constituted one of the varieties of epidemic disease, described by the ancients, under the appellation of Ignis Saeter (which see); and that, instead of being properly imputed to the
admixture of any of these substanices with the corn used for food, the disease is to be ascribed, with more probability to the insufficient nourishment afforded by damaged corn, or the actual death of it, which usually occur together; especially as these diseases have commonly been epidemic in years of scarcity, which is the only circumstance that can be observed in common to all the epidemics described by authors. In addition to the works on ergot and ergot in general referred to, consult, for an account of raphanus, Pultney's View of the Writings of Linnaeus; Rothman's Paper, in the Annates Academ. of Sweden; Tiffot. Epitome Med. Pract.

RAPHANUS, in Botany, the name by which the Atties, among the Greeks, called the radish; for the word raphane, or raphanus, with them, does not express the radish, but the cabbage. The Greek of all other places occurred in calling the radish raphanum, and the cabbage raphana; and it is owing to this that we have many authors who confounded together these two plants, though, to very unlike one another in appearance and use. It is generally to be understood, that wherever Theophrastus mentions the word raphana, he means by it the cabbage; and the same being observed, in regard to all the other Attic writers, the whole danger of confusion and error will cease.

RAPHANISTRUM, a name given by botanists to the wild radish, and designed to express its affinity to the cultivated one. See Raphanus.

Gen. Ch. Caly. Perianth inferior, erect, of four oblong, parallel, converging, deciduous leaves, gibbous at the base. Cor. cruciferae, of four inerely heart-shaped, spreading petals, whose claws are rather longer than the calyx. Nectariferous glands four; one at each side, between the broader flamen and the pilil; and one at each of the opposite sides between the longer flamines and the calyx. Stam. Filaments filis, awl-shaped, erect; two opposite ones the length of the calyx; the rest as long as the claws of the corolla; anthers fimply. Pil. Germin oblong, tumid, tapering, the length of the flamines; tyle fimply; stigmas capitato, undivided. Peric. Pod oblong, pointed, swelling here and there, imperfectly jointed, without valves. Seeds roundish, smooth.

Ofb. Raphanus of Tournefort and Gaertner has a spagyric fruit, of two cells, not burrowing. Raphaniforum of the same family has a jointed fruit, separating at the joints.

Raphanus of Tournefort and Gaertner has a spagyric fruit, of two cells, not burrowing. Raphaniforum of the same family has a jointed fruit, separating at the joints.

1. R. farinus. Common Garden Radish. Linn. Sp. Pl. 955. Willd. n. 1. Ait. n. 1. Ger. Emn. 247. (R. primus; Matth. Valgr. v. 1. 399.)—Leaves veiny. Pod roundish, tumid, of two cells. —The native country of this well-known plant, so commonly cultivated in gardens, is not ascertained. Linnaeus mentions China; but his authority does not appear. Its chief value with us consists in the root, esteemed for its grateful pungency, mixed with a watery cokeleton. The shape of this part varies, from its natural spindly-like figure, to a globular one, and the colour of the skin from purple to white. We doubt much whether the R. niger of Bauhin, commonly called the Black Spanish Radish, which Linnaeus marks , can belong to this species. Its firmness, and black rugged coat, seem to indicate more, than a mere variety. We have not examined the herbage. The leaves of R. farinus are lyrata, notched, and rough, especially the lower ones; the upper part of the herb is smooth, and somewhat glaucescent. Stem branched. Flowers purple, corombole; fruit racemose. Pods erect, tumbid, juicy, pale, glaucous, smooth, slightly fimbriated, various in length and thickness, tipped with an awl-shaped beak. Linnaeus cultivated at Upsal a Chinese variety, or possibly species, whose leaves are broader and smoother, and its whole habit more lax. The oil of the seeds is said to be used in China.

2. R. caudatus. Long-tailed Radish. Linn. Mant. 95. Linn. fl. Plant. Rar. fæc. i. 19. t. 10. Willd. n. 2.—Leaves lyrata. Pod compressed, of one cell, wavy, longer than the whole plant.—Native of Java; where, according to the younger Linnaeus, it is cultivated, and the pickled pods known by the name of Mourgi. In Sweden, as well as in England, it may be treated as a hardy annual, like the foregoing; but the present species does not occur in Hort. Kew., though Mr. Lambert met with it last year in a country garden in Wiltshire. The appearance of the plant, weighed down to the ground by its immoderately long perigitate pods, is altogether extraordinary. The lobes and indentations of the leaves are sharper than in the Common Radish, but the flowers and other parts, except the pods, scarcely betray any difference.

3. R. Raphanistrum. Wild Radish, or Jointed Charlock. Linn. Sp. Pl. 935. Willd. n. 3. Ait. n. 2. Fl. Brit. n. 1, a, d. Eng. Bot. t. 856. Curt. Lond. fæc. t. 46. Mart. Rüht. t. 71. Fl. Dan. t. 678. (R. syylefræus; Ger. Emn. 242.)—Leaves大大提高. Pod round, jointed, even, of one cell. —A troublesome weed in the cornfields of Europe, flowering in June and July. The root is annual, small, and tapering. Stem branched, round, glaucous, rough with prominent bristles, leafy. Leaves rough, lyrata; the upper ones oblong, simply toothed. Flowers numerous, lemon-coloured, changing to white in decay, with purplish veins; sometimes the petals are white from the first. Pods cylindrical, or rather tapering, beaked, knobbed or imperfectly jointed, smooth, becoming fimbriated as they ripen. In a young state they are divided into two cells, but the partition is obliterated, and confounded in one spungy mass, as they ripen. Linnaeus was of opinion that the seeds of this plant caused a convulsive diætæ, thence termed by him Raphania, of which he has given a history in Aeneas. Acad. v. 6. 450, with a figure, and elaborate synonymy of the plant. We have never met with any circumstance to corroborate this hypothesis.

4. R. maritimus. Sea Radish. Sm. Engl. Bot. t. 1643. Ait. n. 3. (R. Raphanistrum; Fl. Brit. 723. R. maritimus, flos lateo, foliaquis articulis, secundum longitudinem eminenter frutis; Ræi Syn. 296. Raphanistrum folio articulata frutis maximis; Færæ. v. 2. 266. Ræi Hih. t. 1. 866.)—Radical leaves interruptedly lyrata. Pod round, jointed, smooth, deeply furrowed, of one cell. —Found on the sea-flora in various parts of Britain, flowering in May. The late Rev. Dr. Walker, and Mr. J. Mackay, observed it on the western coasts of Scotland; and the former cultivated this plant, till his death, as an excellent root, preferable to horde radish; he also found that cattle were very fond of the leaves. Mr. Turner and Mr. W. Borrer gathered the same on rocks, near Beachy Head, Sussex. The root is large and succulent, lating two or three
three years. Stems three or four feet high, round, roughscented at the base. Leaves all rough, and rather sharply toothed; the radicles one: interruptedly spiral, which we have never observed in the last-described species. Flowers of a deeper yellow, and less veiny. Pods strongly jointed, and very deeply furrowed longitudinally, delinute of hairs or other roughnesses. There can be no doubt of this being a distinct species from the former, though generally confounded therewith.

5. R. fabicurus. Siberian Radish. Linn. Sp. Pl. 935. Murray Comment. Gott. for 1775. 48. t. 11. (R. n. 26; Gmel. Sib. v. 3. 266.)—Leaves pinnatifid, somewhat toothed. Pod round, beaked, downy, of one cell.—Native of Siberia. The seeds were sent by Professor Pallas to the Gottingen garden, where the plant flowered in June. Root annual, long, and slender. Stems from three to six inches high; or more, as the seeds ripen, ascending, leafy, hairy, simple or branched. Leaves sometimes elegantly and neatly pinnatifid, almost entire, either in a simple or interrupted manner, roughish at the edge only, sometimes more dilated, with denticulate and branched lobes. Flowers large, yellow, sweet-scented in an evening, their petals strongly enervate. Pods inflexed, copiously and neatly beaded in appearance, rather than distinctly jointed, downy, each with a sharp taper beak.

6. R. tenellus. Slender Purple Radish. Pallas Trav. v. 3. append. 745. t. L f. 5. Willd. n. 5. Ehrh. Sel. n. 38. (Chorispermum tenellum; Brown in Ait. H. Kew. v. 4. 129.)—Leaves smooth, oblong, toothed; the lowermost pinnatifid. Pod awl-shaped, jointed, smooth, of two cells.—Native of defects near the Caspian sea. A hardy annual in our gardens, flowering in June and July. Root long, simple, tapering, and slender. Herb smooth, scarcely branched, leafy. Leaves elliptic-oblong, toothed or pinnatifid, tapering down into longish footstalks. Flowers small, purple. Beak of the pod very long and slender. The ingenious Mr. Brown separates this from Raphanus chiefly, as it seems, because the cotyledons are flat, not folded.

8. R. lanceolatus. Lanceolate Radish. Willd. n. 7.—"Leaves oblong-lanceolate, somewhat toothed at the apex. Pod tumid, smooth, two-celled, with a squarish beak."—Native of the West Indies. Stem a foot and half high, erect, zigzag, with short branches, smooth like every other part of the plant. Leaves flat, oblong-lanceolate; the uppermost lanceolate, narrow, entire; the lower ones bluntly toothed at the extremity. Flowers of a middling size, yellow, in a terminal cluster, six inches long. Pods half an inch long, with a long, obtuse, obscurely quadrangular beak. Willdenow.

9. R. pilosus. Hairy-awl-podded Radish. Willd. n. 8.—"Leaves lanceolate-linear, pinnatifid at the base. Stem rough with bristly hairs. Pod round, smooth, jointed, of one cell."—Native of Guinea. Stem two feet, or perhaps more, in height, branched, divaricated. Leaves three inches long, narrow, smooth, pointed; pinnatifid at the base; toothed in the middle; entire at the extremity. Clyfes; axillary from every leaf, of few flowers. Pods an inch and half long, round, jointed, of one cell, with a short beak, all of them turned one way. Willdenow.

R. erucoides, Linn. Suppl. 299, is rightly referred by Mr. Brown, in Ait. H. Kew. v. 4. 126, to Sinapis Aliniem, Jaq. Hort. Ind. v. 2. t. 168. Willd. Sp. Pl. v. 3. 557. (See Sinapis.) Willdenow cites it, doubtfully, under Brachia Cebratorum of Villars, a very different plant; for which he also by mistake quotes Barcel. t. 1016, a synonym properly belonging to Sisyphrium Barcellieri.

Linnens once referred Bunias Cakite to this genus of Raphanus.

Raphanus, in Gardening, contains plants of the herbaceous, annual, eululent kind, of which the species cultivated is, the common garden radish (R. fatiusus).

There are several varieties; some of which have the appearance of different species, from their shape, size, and colour of the roots; as the long-rooted, which is commonly cultivated in kitchen-gardens for its roots. Of this there are several subordinate variations: as the small-rooted, and the long-rooted crisp-rooted. The small-rooted is most commonly preferred by the gardeners near London, as they require much less room than those with large tops; for as forward radishes are what produce the greatest profit to the gardener, and these are commonly sown upon borders near hedges, walls, or walks, the large-topped roots would be apt to grow more at top, and not swell so much in the root as the other, especially if the plants should be left pretty close.

The small round-rooted, which is not very common here, but in many parts of Italy it is the only one cultivated; the roots of this are very white, round, small, and very sweet. It is now frequently brought to the London markets in the spring, generally in bunches, and is sometimes mistaken there for young turnips, when eaten young, it is crisp, mild, and pleasant.

The large turnip-rooted, or white Spanijs, which has a moderately large, spheroidal white root, and is esteemed chiefly for eating in autumn and the early part of winter. Both these sorts are commonly called indiscriminately turnip radishes.

The black turnip-rooted Spanijs, which has a root like the preceding, white within, but with a black skin; and is greatly esteemed by many for autumn and winter eating. There are likewise some other subvarieties of the radish noticed by gardeners, as the common salmon radish, and the short-topped early salmon radish. Also the small red turnip-rooted radish. Gardeners, too, often call the long-topped fat the fallad radish.

Method of Culture.—These are raised from seed by different sowings from the end of October till April, or the following month. They should have a light fine mould, and the more early sowings be made on borders, under warm walls, or other similar places, and in frames covered by glasses. The common spindle-rooted, short-topped sorts are mostly made use of in these early sowings, the seed being sown broadcast over the beds after they have been prepared by digging over and raking the surface even, being covered in with a light raking. Some few carrots with the early crops of radishes.

It is usual to protect the early sown crops in the borders, during frothy nights and bad weather, by mats or dry wheat straw, which should be carefully removed every mild day. By this means they are brought more forward, as well as form better roots. When mats are used, and supported by pegs or hoops, they are readily applied and removed.

A second
A second more general sowing should be made in January or February. When the crops have got their rough leaf, they should be thinned out, where they are too thick, to the distance of two inches, as there will be constantly more thinning by the daily drawing of the young radishes.

When the weather is dry in March, or the following month, the crops should be occasionally well watered, which not only forwards the growth of the crops, but increases the size of the roots, and renders them more mild and crisp in eating.

And the sowings should be continued at the distance of a fortnight, till the latter end of March, when they should be performed every ten days, until the end of April or beginning of the following month. In sowing these later crops, it is the practice of some gardeners to sow coals-lettues and spinach with them, in order to have the two crops coming forward at the same time, but the practice is not to be much recommended, where there is sufficient room.

But in sowing the main general crops in the open quarters, the market-gardeners generally put them in on the same ground where they plant out their main crops of cauliflowers and cabbages, mixing spinach with the radish-feed as above, sowing the seeds first, and raising them in, then planting the cauliflowers or cabbages; the radishes and spinach come in for use before the other plants begin to spread much, and as soon as these small crops are all cleared off for use, hoe the ground all over to kill weeds and loosen the soil, drawing earth about the stems of cauliflowers and cabbages.

The turnip radish should not be sown till the beginning of March, the plants being allowed a greater distance than for the common spindle-rooted sort. The seeds of this sort are apt to degenerate, unless they are let at a distance from that kind.

The white and black Spanish radishes are usually sown about the middle of July, or a little earlier, and are fit for the table by the end of August, or the beginning of September, continuing good till fruit spoils them. These should be thinned to a greater distance than the common sort, as their roots grow as large as turnips, and should not be left nearer than six inches.

To have these roots in winter, they should be drawn before hard frost comes on, and laid in dry sand, as practised for carrots, carefully guarding them from wet and frost; as in this way they may be kept till the spring.

In regard to the culture of the general crops, they require very little, except occasional thinning where they are too thick, when the plants are come into the rough leaf, either by hoeing or drawing them out by hand: though for large quantities, small hoeing is the most expeditious mode of thinning, as well as most beneficial to the crop by loosening the ground; in either method thinning the plants to about two or three inches distance, clearing out the weakest, and leaving the strongest to form the crop.

In order to save the seed, about the beginning of May some ground should be prepared by digging and levelling; then drawing some of the flaxhight and well-coloured radishes, plant them in rows three feet distant, and two feet another in the rows; observing, if the scion be dry, to water them until they have taken root: after which they will only require to have the weeds hoed down between them, until they are advanced so high as to overspread the ground.

When the seed begins to ripen, it should be carefully guarded against the birds. When it is ripe, the pods will turn brown: then it must be cut, and spread in the sun to dry; after which it must be thrashed, and laid up for use where no mice can come at it.

Method of Culture on Hot-beds.—This method is sometimes practised in order to have the roots early, as in January or the following month. They should have eighteen inches depth of dung to bring them up, and fix or seven inches depth of light rich mould. The seed should be sown moderately thick, covering it in half an inch thick, and putting on the lights: the plants usually come up in a week or two; and when they appear, the lights should be lifted or taken off occasionally, according to the weather; and in a fortnight till the plants to the distance of an inch thick or half two inches, when in six weeks they will be fit to draw. Where there are no frames to spare, the beds may be covered with mats over hoops, and the sides secured by boards and straw-bands. And when in want of dung, if the beds be covered with frames, and the lights put on at night and in bad weather, the plants may be raised for use a fortnight sooner than in the open borders.

RAPHE, in Anatomy, a Greek term, signifying future, applied to some parts of the body; thus we have the raphe corporis calli in the brain (see Brain); raphe penius, feri, and penis. See GENERATION.

RAPHELENGIUS, sometimes called RAPHAELIUS, in Francis, in Geography, a learned orientalist, was born in 1539 at Louny, near Lille, in Flanders. He had the early part of his education at Ghent, but on the death of his father, it was intended to bring him up to trade, and for that purpose he was sent to Nuremberg. Here he had access to books, refined his studies, and took an opportunity of going to Paris, where he made great progress in the Greek and Hebrew languages. The civil wars obliged him to quit France, and he came to England, where, for some time, he taught Greek in the university of Cambridge. After this he returned to the Low Countries, and became a corrector of the press to the celebrated printer Plantin, whose daughter he married in the year 1565. He made himself very serviceable in the printing office, especially with respect to the famous Antwerp Polyglot Bible, printed in 1571, by order of Philip II. of Spain. When Plantin removed to Leyden, he left his business to Antwerp under the care of Raphaelengius, and upon his return the latter went to Leyden. The curators of the university of that place conferred upon him the professorship of Hebrew, to which was added that of Arabic. He died in 1597.

His literary works were "Variae Lectiones et Emendationes in Chaldæicum Bibliorum Paraphrasin," "Grammatica Hebræa," "Dictionarium Chaldæicum," and "Lexicon Arabicum." He had a son of the same name, a man of talents and learning, who published "Notes upon Seneca's Tragedies," and "Eulogies, in Verse, of fifty Perfous, with their Portraits."

RAPHIA, in Botany, from jas. a point or needle, so that it ought to have been Raphis, a genus of Palms, with a very pointed fruit, established by Palliot Beauvois, in his Florid d'Ozanne et de Beain, Tafe. 8.

RAPHIA, in Ancient Geography, a famous city in the Mediterranean, between Gaza and Rhinocorura. This was perhaps Gath of the Rephaim. Raphia is famous for the victory of Philopator, king of Egypt, over Antiochus the Great, king of Syria. (3 Maccab. i. 11.) Josephus says (Antiq. i. xiii. c. 21.) that Raphia was taken by Alexander Janneus, and after being ruined in the wars, was repaired by Gabinius. There are extant some ancient medals struck at Raphia, and some buildings of this city are found in the list of the Jewish councils.

RAPHIDIA, in Entomology, a genus of insects of the order Neuroptera, of which there are two species. The generic character is as follows: Mouth with a curved toothed
RAPER has 1621. the Italy, infruing, 1

however, He the his fou 1553. the Father long has ancient. He the elongated 1646, it and mud There 1544. youger of the chiefly 107 a long Biography, in It Languedoc, Bayle.

RAPHOED, in Geography, a bishopric of Ireland, in the ecclesiastical province of Armagh, which comprises: the greater part of the county of Downeg, being 44 miles in length from north to south, and 32 in breadth, comprehending 515,250 Irish acres. It contains 31 parishes, in which are 32 churches. The dean, archdeacon, and four prebendaries, compose the chapter. The patronage of 6 parishes, which form the corps of the deanery, is in the crown; of 15 others, in the bishop; of 7, in the university of Dublin; and 3, in lay hands. It is not precisely known at what time this fee was founded, but it must have been as early as the ninth century, since bishops of Raphoe are mentioned at that time. Beaufort.

RAPHE, a small post-town of Ireland, the parish church of which serves as a cathedral, where is the bishop's palace. It is 107 miles N. by W. from Dublin.

RAPHE, a township in Lancaster county, Pennsylvania, containing 2814 inhabitants.

RAPHON, in Ancient Geography, a city beyond Jordan, on a brook, not far from Caraim.

RAPICIO, GROVITA, in Biography, an Italian man of letters, was born about the year 1480, at Chiari, in the territory of Brescia. Devoting himself to the instruction of youth in literature, he first opened a school at Bergamo, where he wrote a Latin treatise on the education of youth, which was afterwards printed at Venice. He next taught at Vicenza, and various other cities in Italy, and was for many years employed at Venice in instructing, in polite literature, the youths destined for public life, and among others, the care and instruction of the sons of cardinal Bembo were devolved upon him. Cardinal Pole, in one of his letters, speaks of Rapioc in high terms of commendation. He died at Venice in 1553. He was author of various harangues, poems, and epistles, but his chief work was entitled "De numero Oratorio," in five books, printed at Venice in 1544. "In this," says his biographer, "he minutely investigates the principles of writing the Latin language with sweetness and harmony, and he replies to Melanchthon's affection, that rules of this kind are rendered useless by our ignorance of the ancient pronunciation. Moreri."

RAPID AXN, in Geography, a small river of Virginia, which runs into the Rappahannock, about 10 miles above Fredericksburg.

RAPID PLAT, Ile av, a small island of Upper Canada, in the river St. Lawrence, in front of the township of Matilda, containing about 200 acres.

RAPID RIVER, a river which runs into Hudson's Bay.

RAPIDES, a county of the territory of Orleans, containing three parishes, viz. Rapides, including 2200 inhabitants, Catahoula 1164, and Avoyelles 1209.

RAPIER, properly denotes a long, ordinary, old-fashioned cutting sword, such as those worn by the common soldiers.

The word is formed from the French rapier, of the Greek παρα, eider, to finite, or strike.

In this sense do the French still use the term; so that among them, to take the rapier, is to enter in the army.

RAPIER, in a modern sense among us, usually denotes a small sword, as contradistinguishing from a back-sword, or cutting-sword.

RAPILLO, in Mineralogy, the name given by the Italians to the sand or powders (improperly called ashes) thrown from the craters of volcanoes in immense quantities, towards the conclusion of an eruption. See Volcano, and Volcanic Products.

RAPIN, RENÉ, in Biography, a Jesuit, was born at Tours in 1621. He entered the society in 1639, and was a teacher of the belles lettres in it during nine years. He became eminent by several publications in the Latin and French, and obtained a high rank among the literary characters of his time. It is, however, as a Latin poet that he is chiefly known: his didactic poem on Gardens, entitled "Hortorum, lib. iv." first printed in 1665, has passed through many editions, and has been regarded as one of the most elegant and classical pieces of modern Latin verse. By others it has been thought a work of art and study, rather than an effusion of poetical feeling and fancy, and treats on gardening more as a branch of rural economy than as one of the fine arts. His other Latin poems are sacred elegies, heroic, elegiac, and lyric poems. Father Rapin died at Paris in 1687. He was no less esteemed for his virtues and amiable qualities, than admired for his talents; and he polished all that polished and instructed for the society of the great world, which have distinguished this order from other religious communities. His works were collected and published, in 3 vols. 12mo. 1681. There is a fine edition of his "Hortorum," published by Brotier at Paris, in 1780. Rapin was great as a critic, in which line he is known by his "Réflexions sur l'Eloquence, sur la Poésie, sur l'Histoire, et sur la Philosophie," and also by his "Comparaisons de Virgil et d'Homcre," printed in 2 vols. 4to. Bayle. Moreri.

RAPIN DE THOYRAS, PAUL, well known as the historian of England, was born at Calais, in Languedoc, in 1601. He was descended from a noble family of Savoy, which came into France in the reign of Francis I., for the sake of professing the reformed religion. The subject of this article, after having received his education, went to his father, who was an advocate in the chamber of the edict at Nantes, for the purpose of studying the law. He was in due time admitted an advocate, but the chamber being suppressed in the same year, he went with his father to Toulouse. On the revocation of the edict of Nantes, in 1685, he withdrew to England, after which he went to Holland, and entered into a company of French cadets at Utrecht. In 1686 he followed the prince of Orange into England, and obtained an enligency in lord Kingston's regiment, which went to Ireland. He was engaged in several battles, particularly at the siege of Carrickfergus and Limerick, and at the battle of the Boyne, and so much distinguished himself, that he obtained a captain's commission. In 1693 he was nominated governor to the son of the earl of Portland, resigned his commission to a younger brother, and received from the crown, for his part services, 100l. a-year. He travelled to different countries in company with his pupil, and resided with him some time at the Hague. By the death of king William he was deprived of his pension, and his engagement as private tutor being over, he retired, in 1707, to Wefel, in the duchy of
of Cleve, where he devoted himself to the composition of the history of England. Here he died in 1725. He had, previously to his decease, published in the year 1717, "Dissertation sur les Whigs et Tories," which was translated into English. His great work, "L'Histoire deAngleterre," was printed at the Hague in 9 Rolls, 410, in the years 1725-6. It commences with the remotest periods, and is brought down to the proclamation of William and Mary. It has been twice translated into our own language, and was, till the appearance of Hume, the most popular history of England, and Tindal's, or rather Birch's, and other continuations, have been adapted to it. It is written in a prose and unadorned style, but deferves the praise of much solid information. "His work," says an excellent writer, "is of great authority, on account of his perpetual references to original documents, and the ample quotations which he frequently makes from important late papers, confer upon it additional value. He has so copiously detailed the matters which were agitated in the turbulent, but prudent parliament of Charles I., as to give a clear view of the rife of those parties which to this day divide the people of England. On the dark and horrible transfigurations of the reign of Charles II. he perhaps throws as much light as it is now possible to obtain. In reference to that important period, he has treated historical difficulties with candour, and in dissecting the merits and demerits of parties, he has weighed evidence with laudable scrupulousness." (See Shepherd's "Systematic Education"). Rapin, during the collection of his materials, undertook the useful labour of making an "Abridgement of Rymer's Foedera," which was published in Le Clerc's "Bibliotheque Choix," and translated into the English by Mr. Stephen Whatley, and published in 1742, under the title of "Acta Regia," and in folio.

Rapine, Rapina, in Law. To take a thing in private; against the owner's will, is properly theft; but to take it openly or by violence, is rapine, or robbery.

Rapinia, in Botany, was so called by Loureiro, Fl. Cochinch. 127, after father Rene Rapin, a French Jesuit, author of an elegant Latin poem on gardens, who died in 1687, aged 66. If this writer contributed nothing to improve the science of botany, he has, doubtless, helped to promote a love of plants, and may therefore claim a botanical wreath. A Jesuit of his day was doubly entitled to respect, for having, like the good Loureiro, turned his mind to an elegant and improving pursuit, from these two corruptors of the human heart and understanding, political intrigue, and scholastic divinity; in which most of his brethren fought their temporal, and ofteningly their eternal, good. The Rapinia of Loureiro however, proved, on the examination of his specimens by the late Mr. Dryander, to be the Sphene-calea of other authors; and this last-mentioned name is now generally adopted. See that article.

Rapino, in Geography, a town of Naples, in Abruzzo Citra; nine miles S. of Civita di Chieti.

Gen. Ch. Cal. Parietian inferior, of four oblong, spreading, deciduous leaves, gibbous at the base. Cor. cruciform, of four obvate, entire, spreading petals, whose claws are shorter than the calyx. Stam. Filaments fix, about the length of the calyx, the four opposite ones rather the longest; anthers simple. Pfyl. German oblong; style awl-shaped, the length of the calyx; stigma obtuse. Peric. Pouch lenticular, pointed, corrugated, of two cells, and two cohering, not spontaneously separating, coriaceous valves; partition membranous. Seeds roundish, solitary in each cell; cotyledons flat.

Eff. Ch. Calyx spreading. Pouch of two cells, and two convex valves, not curving.

1. R. paniculatum. Panicked Rapistrum. Ait. n. 2. (R. arvenae, folio auriculato acuto; Tourn. Infl. 211. Myagrum paniculatum; Linn. Sp. Pl. 894. Wildl. Sp. v. 3. 409. Fl. Dan. t. 204. Myagro similis, filgue rotundata; Bauld. Prodr. 52.)—Native of cultivated fields in various parts of Europe, from Sweden to Greece, but not, as yet, observed in Britain. Root annual, tapering. Stem about two feet high, erect, round, roughish, leafy, branched. Leaves oblong, acute, undivided, rough, somewhat toothed, clasping the stem with their arrow-shaped base. Flowers small, yellow, in numerous clusters, which become greatly elongated when in fruit. Pouch scarcely bigger than mustard; a little abrupt, finely reticulated. One of the seeds is often, but not always, abortive. Mr. Brown refers to this genus the Bunius egyptianus of Linnæus, which agrees with our R. paniculatum in having flat, not spiral, cotyledons, but has otherwise the characters of Bunius.

Rapistrum is also a species of the fæt-cabbages, or crambs.

Rapolla, in Geography, a town of Naples, in Baflicata, the seat of a bishop, united to Melfi; six miles W. of Venosa. N. lat. 45° 58'. E. long. 15° 44'.

Rapore, a town of Naples, in Principato Ultra; 9 miles E. of Conza.

Raposo, a town of South America, in the country of Popayan.—Also, a river of Popayan, which runs into the Pacific ocean, N. lat. 3° 48'. E. long. 84°.

Rappa-Nanco, a large navigable river of Virginia, which rises in the Blue Ridge, and runs about 150 miles from N.W. to S.E., and enters into Chesapeake bay, between Westmill and Stingray points. It waters, in its course, the towns of Falmouth, Frederickburg, Port-Royal, Leeds, Tappahannock, and Urbonne.

Rappe, in Commerce, a money of account in Switzerland, 10 of which are equal to a good batze; and 6 are equal to a plappert, shilling, or esculin. This is the cafe at Basil, but at Lucern the plappert is only 3 rappen, and the Zurich esculin = 32 rappen.

Rappe, in Ichthyology, a name given by some to the capito flexuilla rapo of Gfner, more frequently known by the name of the corpus pleis.

Rapperschweit, in Geography, a town of Switzerland, and capital of a district to which it gives name; situated on the N. side of the lake of Zurich, over which there is a bridge, 1852 paces in length, built in 1538 by the counts of Habsburg. The town was founded in 1091, and formerly had its own counts. In 1538 it was sold to the fons of Albert, archduke of Austria. In 1464 it put itself under the cantons of Uri, Schwitz, Unterwalden, and Glarus, with a reference of its liberties; but the cantons gradually made themselves masters of it. At the peace of Aarau in 1712, its liberties were restored, though the country remains subject to the sovereignty of Zurich and Berne; 15 miles S.E. of Zurich.

Rappin, a town of Anterior Pomerania; 7 miles N. of Bergen.
R A R

RAPPO, a bay on the coast of Mowee, one of the Sandwich islands.

RAPPOLTSKIRCHEN, a town of Austria; five miles S. of Tuln.

RAPPORT, Fr. in Mykie, is sometimes used for proportion, and sometimes for relation, words which will be explained in their places.

RAPPS, in Geography, a town of Austria, on the river Taya; four miles S.W. of Drosendorf.

RAPSO, a town of Iliria; 52 miles S.E. of Capo d'Illiria.

RAPTEC, a river of Hindoostan, which runs into the Dewith, five miles S.W. of Selkempour.

RAPTU HEREDIT, in Law, an ancient writ which lies for taking away an heir, holding in loco; of which there are two forts; one when the heir is married, the other when not. See Ravishment.

RAPTURE, RAPTURA, an extacy, or transport of mind. See Extasy, Extremity, Rhapsody, &c.

RAPUNCULUS, in Botany, the Rampion, owes its name to a resemblance in the root to a Rape, or oblong Turnip. This root, Campanula Rapunculus of Linnaeus, is biennial, scarcely larger than a radish, which it resembles also in shape, but the colour is white. Its flavour is sweet and mild, notwithstanding some degree of milkiness in the juices, in which it accords with other, usually bitter and acrid, species of its genus. The Rampion is now much less cultivated than formerly, and almost a stranger at our tables.

RAPUNTUM, a name used by Tournafort and Morison for some plants referred to Lobelia by Linnæus. (See Lobelia.) Gertner, having adopted Plu mière's Lobelia, the Linnæian Scævola, renders Rapuntum; but such a measure could now lead to inconvenience only.

RAPUTIA, so called by Aublet, because the plant grows in the forests of Oropus in Guiana. Jullien and Lamaraek have retained this curious name. Schreber has changed it for Scœnia; see that article hereafter.

RARAKIT, in Geography, a town of the island of Ceram, at the foot of a mountain covered with trees, which serves as a harbour for pirates.

RARE, in Physis, denotes a body that is very porous, whose parts are at a great distance from one another, and which contains but little matter under a great deal of bulk. In this sense rare flaments opposed to dense.

The corpuscular philosophers, viz., the Epicureans, Gæfendits, Newtonians, &c. affirm that bodies are rarer some than others, in virtue of a greater quantity of void included between their pores. The Cartesians hold, that a greater rarity only consists in a greater quantity of matter subtilis included in the pores. Lastly, the Peripatetics contend, that rarity is a new quality superinduced upon a body without any dependence, either on vacuity, or subtile matter.

RARECOURT, in Geography, a town of France, in the department of the Meule; 10 miles S.W. of Verdun.

RAREE, a town of Hindoostan, in Conce; 20 miles N.N.W. of Goa.—Also, a town of Hindoostan, in Bahar; 11 miles N.N.W. of Durbangh.

RAREFACTION, Rarefactio, in Physis, the act by which a body is rendered rare; that is, is brought to pollens more room, or appear under a larger bulk, without accession of any new matter.

Rarefaction is opposed to condensation.

Our more accurate writers restrain rarefaction to that expansion of a mass into a larger bulk, which is effected by means of heat. All expansion from other causes they call dilatation.

The Cartesians deny any such thing as absolute rarefaction: extension, with them, constituting the effence of matter, they are obliged to hold all extension equally full.

Hence, they make rarefaction to be no other than an accession of freth, subtle, and ineffible matter, which, entering the parts of the body, sensibly dilates them. See this disproved under Vacuüm.

It is by rarefaction that gunpowder has its effect; and to the same principle also we owe our æolipiles, thermometers, &c.

The degree to which the air is rarefiable exceeds all imagination: Merlennus, long ago, by means of an intense heat, found that air might be rarefied to as to pollens more than seventy times its former space.

Mr. Boyle afterwards found, that air, by its own elasticity, and without the help of any heat, would dilate itself so as to take up nine times its former space; then 31 times; then 60; then 150: at length, by many degrees, he found it would reach to 8000 times; then 10,000, and finally to 15,679.

Such is the rarefaction of common air, from its own principle of elasticity, and without any previous condensation, but if it be compressèd, the same author found its greatest space when most rarefied, is to its least when most condensed, as 55,000 to 1.

Such an immense rarefaction, for Isaac Newton shows, is inconceivable on any other principle than that of a repelling force inherent in the air, by which its particles mutually fly from one another.

This repelling force, he observes, is much more considerable in air than in other bodies, as being generated from the moat first bodies, and that with much difficulty, and scarcely without fermentation; those particles being always found to fly from each other with the moat force, which, when in contact, cohere the matter firmly. See Air.

The members of the French Royal Academy have bestowed much attention on the different rarefactions, or rather the different rarities of the air at different heights. M. Mariotte established this as a principle, from experiments, that the different rarefactions, or condensations, of the air, follow the proportion of the weights with which it is pressed.

Hence, supposing the mercury in the level of the sea suspended to twenty-eight inches, which is the weight of the whole atmosphere, and that fifty feet height of air are equivalent to a line, or one-twelfth of an inch of mercury; so that the barometer, at the height of fifty feet from the sea, would fall a line; it is easy finding what height of air would be equal to a second, or any line of mercury: for as twenty-eight inches of mercury one-twelfth are to twenty-eight inches, so is the height of fifty feet of air to a fourth term, which is the height of air corresponding to a second line of mercury.

And after the same manner may the height of air corresponding to each line be found; which will make a geometrical progression, the sum of which will be the whole height of the Atmosphère (which fec); and, of course, a certain part of that sum will be the height of a mountain, at what top the barometer shall have sunk a certain quantity.

Meffrs. Cuffini and Maraldi, upon measuring the heights of several mountains, found, that this progression of M. Mariotte was defective; that it always gave the height of the mountains, and consequently the rarefactions, less than they really were; and from some further experiments, M. Aon-
M. Amontons found, that the principle will only hold in the mean rarefactions, not in the extremes. See Barometer.

RAREN, or Raron, in Geography, a town of the Valais, and capital of a tithing; 21 miles E. of Sion.

RARGIARA, a town of Hindooftan, in Bahar; 32 miles S.W. of Bahar.

RARRTON, a river of America, in New Jersey, formed by two considerable streams, called the north and south branches; the one rises in Morris county and the other in the county of Hunterdon. This river passes by Brunswick and Amboy, and, uniting with the waters of the Arthur Kull found, helps to form the fine harbour of Amboy. At Rariton town, through which this river passes, is a small cascadel, with a full of water from fifteen to twenty feet, romantically situated between two rocks. Copper ore has been found upon the upper part of this river.

RATITON, a town of New Jersey, situated between the mouth of the N. branch of the above river and Roundbrook; 12 miles N.W. of Brunswick.

RARO, a town of Hungary; 8 miles E.S.E. of Altenburg.

RARONGHAKON, a large lake of Thibet. N. lat. 31° 4'. E. long. 83° 52'.

RARUM, Non-Spiffam, in the Ancient Muses. See Apyccon.

RAS, in Geography, a town of Syria, newly called "Conna," situated near the source of the Orontes; 24 miles N. of Balbec.

Ras Abd, or Baba, a cape on the coast of Arabia, in the Red sea; 10 miles S.S.W. of Jiddah.

RAS-Acon-natter. See CAXINES.

Ras Adder. See Cape Bon.

Ras Abyssab, a cape on the coast of Arabia, in the Red sea. N. lat. 18° 19'. E. long. 37° 48'.

Ras Ain, or Ain Verbeh, a town of Ahsatic Turkey, in the province of Diarbekir; 80 miles S. of Diarbekir. N. lat. 35° 34'. E. long. 39° 48'.

Ras el Amouf, a cape of Africa, on the coast of Algiers; 42 miles E. of cape Tennes. N. lat. 36° 41'. E. long. 2° 48'.

Ras Affab, a cape on the coast of Abyssinia, in the Red sea. N. lat. 13° 8'. E. long. 43° 10'.

Ras el Camir or Kasfar, or cape of the wild bear, a town of Syria, in the pachalic of Aleppo, near a cape on the sea-coast; 16 miles W. of Alexandria.

Ras el Daor, a cape on the coast of Nubia, in the Red sea. N. lat. 21° 21'. E. long. 36° 9'.

Ras el An if or Enf, i.e. cape of the Roffe, on the coast of Egypt, in the Red sea; without tree or herb; in the front of the point are the remains of a large temple. N. lat. 23° 57'.

Ras Fortach. See FARTACH.

Ras Filliam, a cape on the coast of Arabia; 18 miles S.E. of cape Mozendum. N. lat. 20° 65'.

Ras Ibrabim, a cape of Arabia, in the Red sea; 6 miles S. of Guinea.

Ras Igudid, or Ras el Jidid, a cape of Nubia, in the Red sea; near which is a harbour, resembling a caledron, and round the arch of a circle; the entrance is formed by two points, N. and S. of each other, with 18 fathoms of water, and in the harbour 13. This port is subject to no inconvenience, except from the caff. N. lat. 22° 15'. E. long. 36°.

Ras al Mabbet, a cape of Africa, on the coast of Tripoli. N. lat. 32° 18'. E. long. 11° 49'.

Ras Mohammed, a cape on the coast of Arabia, in the Red sea. N. lat. 25° 54'.

Ras al Mary, a town of Peria, in the province of Segelgn; 200 miles S.W. of Zareng.

Ras al Najf, a cape of Egypt, in the Red sea. N. lat. 23° 18'.

Ras Roz, a cape on the E. coast of Arabia. N. lat. 21° 55'.

Ras Virda, or Ras el Zafra, a cape on the coast of Arabia, forming the S. point of the gulf of Curia Muria. N. lat. 17° 65'.

Ras Zafra, a cape on the coast of Egypt, in the Red sea; 32 miles S.E.S. of Suez. N. lat. 29° 14'.

RASA, a small island in the Indian sea, near the coast of Africa. S. lat. 17° 8'.

RASAIN, a town of Peria, in the province of Fars or Farsian; 110 miles N.W. of Schiras or Shiraz.

RASAL, or Rasal-sem, Cape, a cape of Africa, on the coast of Tripoli. N. lat. 32° 36'. E. long. 21° 10'.

RASALEMA, a river of Africa, which waters the city of Fez.

RASALGATA, Cape, or Ras Rouf, a cape on the E. coast of Arabia. N. lat. 22° 25'. E. long. 58° 15'.

RASANT, or RAZANT, blank, in Fortification. See FLANK.

The defence of the baflion is rafant.

RASANT Fare. See FIRE.

RASCA, in Geography, a river of Servia, which joins the Ibar; 16 miles N.E. of Jembafl.

RASCETA, a word used by the Arabian physicians to express the writ or ankle.

RASCH, in Geography, a town of Bavaria, in the territory of Nuremberg; two miles S.E. of Altorf.

RASCHNA, or RIZANA, a town of Servia; in eight miles S. of Parkin.

RASCOWITZ, a town of Bohemia, in the circle of Letmertz; four miles E. of Auiche.

RASCIA, a port of Servia, watered by the Rafea.

RASCINES, a town of Spain, in the province of Biscay; 21 miles S.E. of Santander.

RASE, RASARIUM, in our Old Writers, feems to have been a meafure of corn now difputed; toll shall be taken by the rafe, and not by the heap or cantel.

RASE, in the Manege. To rafe, or glance upon the ground, called in French rafez le lapas, is to gallop near the ground, as our English horses do.

RASEB, AL, in Geography, a fortified pafs in the mountains of Grand Bucharia; 60 miles N. of Vaflagonal.

RASEBOURG, a fea-port town of Sweden, in the gulf of Finland; 30 miles S.E. of Abo.

RASEC, a town of Peria, in the province of Segelgan; 60 miles S.W. of Zareng.

RASGRAD, or RANGHAT. See HIRASGRAD.

RASH, in Clock-Work. See RATCH.

RASH, in Medicine, an eruption or efflorescence upon the skin, thrown out in fevers, or furfeits.

RASHAUA, in Geography. See RASSAGU.

RASHD, a town of Nubia, in Sennaar; 15 miles N. of Gieflim.

RASCUILMO, Cape, a cape on the N. coast of Sicily. N. lat. 38° 18'. E. long. 12° 49'.

RASIREE, or RAZIEREE, in Commerce, a meafure of corn in Dunkirk and Flanders. At Dunkirk, they have the fee rafeere, and the land rafer; 8 of the former being = 9 of the latter; 54 fee rafeere or 60 land raferes answer to 31 English quarters. Each fee rafeere contains 9884 inches, and each land rafer contains 8786 inches; 1740 of the former, and 19.57 of the latter, are equal (each) to 10 English
RAS

English quarters. At Dixmude 29.51 raifers are equal to 10 English quarters, and each raifer contains 582.1 inches. At Gravelines 21.29 raifers are equal to 10 English quarters, and each contains 8880 inches. At Nieuport 16.93 raifers are equal to 10 English quarters, and each raifer contains 10177 cubic inches. At Olfend 16.02 raifers are equal to 10 English quarters, and each of them contains 10733 inches. At St. Omer 21.77 raifers = 10 English quarters, and each quarter contains 7500 cubic inches. At Life or Lille, the raifer is divided into 8 parts; of these there are two forts, one, used for wheat or rye, the other, called raifer de Mars, for oats or beans; of the former, and 40 of the latter, are reckoned for one half. The raifer of wheat weighs about 128 lbs., and 4 of these are equal to 19 feet, Paris measure, or about 107 English quarters; 39.64 raifers of Life are equal to 10 English quarters, and each contains 4339 cubic inches.

RASILIS ERUGO, in the Materia Medica of the Ancients, one of their kinds of verdigris. It was prepared in the following manner; they set some sharp vinegar over the fire in a strong earthen vessel, and covered it with a brass pot inverted, well cleaned, and without any vent-hole. And after some time the vessels were to be separated; and the verdigris, which was found concreted on the inner side of the brass pot, was scraped off, and put up for use.

RASILITA, in Geography, a town of Italy, in Friuli; 26 miles S.S.E. of Friuli.

RASIN, a town of Hindoostan, in Dowlatabad; 18 miles W.S.W. of Carmuliah.

RASINTA, a town of Italy, in Friuli; 14 miles N. of Udina.

RASKOW, a town of Poland, in the patinate of Bialowieza; 54 miles S. of Bracław.

RASMAN, an island in the Red Sea. N. lat. 13° 58'.

RASMEND, a mountain of Peria, in the province of Irak; 60 miles N.E. of Nahevan.

RASNO, an island in the Adriatic. N. lat. 44° 6'. E. long. 15° 25'.

RASOR, or Ell of Turin, in Commerce, is equal to 22 Genoese palmi, or 23 English inches; the foot 143.2 French lines, or 3.17 English inches; hence 180 Piedmontese rafi are equal to 100 English yards, and 33 Piedmontese feet = 35 English feet. At Cagliari, 166.7 rafi = 100 English yards, and each of them equal to 21.6 English inches. At Chambery 195.5 rafi = 100 English yards, and each = 22.7 English inches. At Nice, 166.7 rafi = 100 English yards, and each = 21.6 English inches; 154.5 rafi of Turin = 100 English yards, and each = 23.3 English inches.

RASP, a coarse fort of tile.

RASPERCH, in Geography, a town of Austria; eight miles E. of Zvetl.

RASPERATORIUM, (from rado, to scrape,) a surgical instrument with which the peritonitis was, by the old practitioners, scraped from the bones, and the bones themselves sometimes rasped.

RASPBERRY BUSH, in Botany. See RUBUS.

For the dietetic and medicinal use of raspberries, see Summer Fruits.

RASPECON, in Ichthyology, a name given by fome to the uranocope, or itar-gazer.

RASPENBURG, in Geography, a town of Germany, in the principality of Weimar, near which are some medicinal springs; 12 miles N. of Weimar. N. lat. 51° 13'; E. long. 11° 35'.

RASPHEYS, or Raps-houses, a celebrated work-house, or house of correction, at Amsterdam. See Work-house. Vol. XXIX.

RASPUGLY, in Geography, a town of Bengal; four miles S. of Calcutta.

RASSADRES, a cluster of small islands, in the river St. Lawrence. N. lat. 48° 15'. W. long. 68° 48'.

RASSAGU, one of the Katur or Karilsky islands, lying 40 verfs from Mutova, and in extent about 30 verfs measured either way. It has lofty mountains and steep rocky shores, with very few sandy bogs. On the mountains, here and there, is a good foreif of birch, alders, and the nut-bearing pine; the vales and flats abound in herbs. On the land is no other animal besides the fox, but the cliffs of the rock afford nesting-places for all kinds of sea-birds; and the beavers and seals lie feated on several parts of the island. Here are no trees that yield fish. The Kurils on this island are not numerous, and some of them are baptized.

N. lat. 48° 20'. E. long. 15° 4° 13'.

RASSE, in Natural History, a name given by the Ceylonese to a particularly fine kind of cinnamon, which is the bark of a tree, growing no where but in that island. The name they give it signifies foarp or blying cinnaia. This choice kind was formerly exported annually, in considerable quantity, by the Dutch East India company, who prohibited the mixing any other kind of cinnamon with it, under a very severe penalty. Phil. Trans. 1749.

RASSOULPOUR, in Geography, a town of Hindoostan, in the cirque of Nagore; 22 miles N.W. of Didwana.—Alfo, a town of Hindoostan, in the cirque of Gohud, on the Jumna; 40 miles E. of Gohud.

RASSOVAT, or AXPOOT, a town of European Turkey, in Bulgaria; 24 miles N. of Dristra. N. lat. 44° 25'. E. long. 27° 37'.

RASTEFIT, a town of the duchy of Baden, situated on a large plain on the river Mers; the town is new, and regularly built, and the principal street is broad and handsome; 16 miles S.W. of Durlach. N. lat. 48° 52'. E. long. 8° 15'.—Alfo, a town of Bavaria, in the bishoipric of Bamberg; five miles N.W. of Bamberg.—Alfo, a town of the duchy of Wurzburg; three miles S. of Melrichstadt.

RASTAGARA, a town of Egypt; 90 miles E. of Cairo.

RASTEDE, a town of Germany, in the country of Oldenburg; 11 miles N. of Oldenburg.

RASTENBURG, a town of Prufia, in the province of Na-ting, founded in 1329, and after having been defended by the Lithuanians in 1348, was rebuilt, together with its faif, and put into a better state of defence; it is enclosed by a wall, and, in 1665, surrounded by a rampart. The burghers, most of whom are Lutherans, are about 200. The inhabitants derive their subsistence from a little commerce, brewing, agriculture, and mechanic trades; 46 miles S.E. of Königsberg. N. lat. 53° 58'. E. long. 11° 27'.

RASTICO HARBOR, Grand, a bay in the gulf of St. Lawrence, on the N. coast of the island of St. John. N. lat. 46° 25'. W. long. 62° 50'.

RASTORFF, a town of Austria; seven miles E. of Ehringsbrunn.

RASTOWICA, a river of Poland, which runs into the Dnieper, on the borders of Russia.

RASURA, a word used by the pharmacie writers to express the shavings of woods, or other hard substanfes, to make them readily yield their virtues by decoction. Physicians alo use it to express the corfonation of acid humour.

RASURE IN A DEED, in Law. See DEED.

RASZNA, in Geography, a town of Servia; 24 miles N. of Niha.

RAT, in Zoology. See Mus.
It has been observed that this country was formerly infested with two kinds of rats, the house-rat and the water-rat; but that it is believed that the latter, within this last half century, has destroyed the former. This is probably, however, only imaginary, since it is well known that the house-rats are frequently brought, in great abundance, into the different sea-ports of the kingdom, in corn, and other vessels. It seems not improbable, but that these different varieties of rats may intercropulate, and by that means the latter become house-rats, as there is considerable diversity in the colour of the house-rats, some approaching to nearly black, which is the natural colour of the water-rat, while the genuine house-rat is always of a darkish or dapple brown. In their habits they have some circumstances in which they agree, as in that of making burrows in the ground; but the water-rat is capable of living much in the water, and of feeding on fish and other aquatic animals, while the house-rat mottly lives upon grain, and other produce of that kind. The water-rats are also laid, by Dr. Darwin, to eat the foliage as well as the seeds and fruits of vegetables, as he has seen a young rat of this kind devour a large leaf of the water-plantain (allium plantago). They likewise, as well as the house-rats, are destructive of young animals, such as ducklings, goslings, chickens, and rabbits. But the great mischief which the water-rats produce, in feeding on, and destroying, the roots of a great variety of vegetables, is their innumerable burrows. The above writer remembers to have seen some new-planted apple-trees taken out of the ground with nearly the whole of their smaller roots eaten, and the larger ones peeled by them. With the house kind, they are, likewise, extremely destructive of the food of poultry, and fowls, and of course are highly detrimental near waters. It is remarked by the above able writer, that as these animals, like the dog, are of a lazievous nature, and, as some materials have a strong scent, refraining, perhaps, that of their venereal organs, they are liable to be attracted by such smells, as dogs are, on the same account, he supposes, inclined to roll themselves in putrid carrion; and male cats to eat marum valerian, and cat-mint. It is of this principle that rat-catchers avail themselves, and by indulging the propensity, deceiving them to their destruction, by blending with their favourite foods different strong-scented substances, such as the essential oil of rhodium, or mulk, with the poisonous powders of strychna nux vomica, or of delphinium flavifragia, or perhaps of arsenic.

The first step taken by rat-catchers, in order to clear a house, &c. of those vermin, is to allure them all together, to one proper place, before they attempt to destroy them; for there is such an instinctive caution in these animals, accompanied with a surprising sagacity in discovering any cause of danger, that if any of them be hurt, or purified, in an usual manner, the rest take the alarm, and become so shy and wary, that they elude all the devices and stratagems of their puruers for some time after. The place where the rats are to be assembled, should be some closet, or small room, into which all the openings, but one or two, may be secured; and this place should be, as near as may be, in the middle of the house, or buildings. It is the practice, therefore, to attempt to bring them all together in some such place before any attempt be made to take them; and even then to avoid any violence, hurt, or fright to them, before the whole be in the power of the operator. In respect to the means used to allure them to one place, they are various; one of those most easily and efficaciously practised is the trailing some piece of their most favourite food, which should be of the kind that has the strongest scent, such as toasted cheese, or broiled red-herring, from the holes or entrances to their acceses in every part of the house, or contiguous buildings, whence it is intended to allure them. At the extremities, and in different parts of the course of this trailed tract, small quantities of meal, or any other kind of their food, should be laid, to bring the greater number into the tracks, and to encourage them to pursue it to the centre place, where they are intended to be taken; at that place, where time admits of it, a more plentiful repast is laid for them, and the trailing repeated for two or three nights. But besides this trailing, and way-baiting, some of the most expert of the rat-catchers have a shorter, and, perhaps, more effectual method of bringing them together, which is, the calling them, by making such a kind of whistling note as resembles their own call, and by this means, with the assistance of the way-baits, they call them out of their holes, and lead them to the repast prepared for them at the place designed for taking them. But this is much more difficult to be practised than the art of trailing; for the learning the exact notes, or cries, of any kind of beasts or birds, so as to deceive them, is a peculiar talent, not easily attained in other cafes.

And in practising either of these methods great caution must be used by the operator to suppref, and prevent, the scent of his feet and body from being perceived; which is done by overpowering that scent by others of a stronger nature. In order to this the feet are to be covered with clothes rubbed over with affalatidos, or other strong fnelling substances; and even oil of rhodium is sometimes used for this purpose, but sparingly, on account of its dearness; though it has a very alluring, as well as disfiguring effect. If this caution of avoiding the scent of the operator's feet, near the track, and in the place where the rats are supposed to be collected, be not properly observed, it will very much obstruct the success of the attempt to take them; for they are very shy of coming where the scent of human feet lies very fresh, and intimate, to their fagacious instinct, the presence of human creatures, whom they naturally dread. To the above-mentioned means of alluring by trailing, way-baiting, and calling, is added another of very material efficacy, which is the use of oil of cats, which, like the marum, is the chief of the cats of rats, has very extraordinary and fascinating power on these animals. The oil is extremely dear, and therefore very sparingly used. It is exhaled in a small quantity in the place, and at the entrance of it, where the rats are intended to be taken, particularly at the time when they are to be led brought together in order to their destruction; and it is used also, by inreasing it on the surface of some of the implements used in taking them, by the method before described, and the effect it has in taking off their caution and dread, by the delight they appear to have in it, is very extraordinary.

It is usual, likewise, for the operator to disguise his figure as well as scent, which is done by putting on a coat of gown or cloak, of one colour, that hides the natural form, and makes him appear like a poll, or such inanimate thing; which habit might likewise be esteemed as above, to overpower the smell of his person; and besides this he is to avoid all motion, till he has secured his point of having all the rats in his power. When the rats are thus enticed and collected, where time is afforded, and the whole in any house or out-buildings are intended to be cleared away, they are suffered to regale on what they most like, which is ready prepared for them; and then to go away quietly for two or three nights; by which means those which are not allured the first night are brought afterwards, either by their fellows, or
the effects of the trailing, &c., and will not fail to come duly again, if they are not disturbed or molested. But many of the rat-catchers make shorter work, and content themselves with what can be brought together in one night or two; but this is never effectual, unless where the building is small and entire, and the rats but few in number.

With respect to the means of taking them when they are brought together, they are various. Some entice them into a very large bag, the mouth of which is sufficiently capacious to cover nearly the whole floor of the place where they are collected; which is done by spreading some vellet, placed in the middle of the bag, with oil of rhodium, and laying in the bag baits of proper food. This bag, which before laid flat, when the oil is poured in, with the mouth spread open, is to be suddenly closed when the rats are all in it. Others drive or frighten them, by flight noises or motions, into a bag of a long form, the mouth of which, after all the rats are come in, is drawn up to the opening of the place by which they entered, all other ways of retreat being secured. Others, again, intoxicate or poison them, by mixing with the repast prepared for them the cocculus indicus, or the nux vomica. A receipt for this purpose has appeared, which directs four ounces of cocculus indicus, with twelve ounces of oatmeal, and two ounces of treacle or honey, to be made up into a moist pille with strong beer; but if the nux vomica be used, a much less proportion will serve than is here given of the cocculus. Any similar composition of these drugs, with that kind of food the rats are most fond of, and which has a strong flavour, to hide that of the drugs, will equally well answer the end. If, indeed, the cocculus indicus be well powdered, and infused in strong beer for some time, at least, half the quantity here directed will serve as well as the quantity previously mentioned. When the rats appear to be thoroughly intoxicated with the cocculus, or sick with the nux vomica, they may be taken with the hand, and put into a bag or cage, the door of the place being first drawn to, left those which have strength and fensible remaining should escape. By these methods, when well conducted, a very considerable part of the rats in a farm, or other house, and the contiguous buildings, may be taken and destroyed. But various other methods have been practised.

In the Transactions of the Bath Agricultural Society, the following compositions are advised for destroying these mischiefous creatures, and which are rated to have been attended with great success. First, to a quart of oatmeal, add six drops of oil of rhodium, one grain of musk, and two or three of the nuts of nux vomica finely powdered; make them into pellets, and put them into the rat-holes. This, it is said, was at first greedily eaten, and did great execution; but the wife animals, after a time, ceased to eat it. Secondly; this conformed of three parts of oatmeal and one of flax's-acre, mixed well into a pille with honey. Pieces of this pille were laid in their holes, and again did great execution. Thirdly; this is a method of destroying them by laying a large box down on its front side, with the lid supported open by a string over a pulley; and by trailing toasted cheese and a red-herring from their holes to this box, and placing oatmeal and other food in it, which they are for a few nights to be permitted to eat unmolested; and finally to watch them by moon-light, the inside of the box being painted white; and, when many of them are seen, to let down the lid; by which contrivance fifty of them are flated to have been taken at one time.

But though the usual ways of destroying rats are by traps and poison, Mr. Forfyth advises never to use arsenic, or corrosive sublimates, for that purpose, except under particular circumstances, as they are deadly poisons: nux vomica will, he thinks, generally answer the end as well, without the danger. He suggests it as a very good plan, to prevent accidents, to enclose the traps in cafes, having holes in the ends of them large enough to admit rats, but small enough to exclude dogs, cats, &c. And that, as a bait for rat-traps, the following composition may be made ufe of with advantage. Take a pound of good flour, three ounces of treacle, and fix drops of the oil of caraways: put them all in a dish; and rub them well together till they are properly mixed; then add a pound of crumb of bread. The traps baited with this mixture should be set near their haunts as possible; but, for two or three days, so as not to fall or drive rats to the rats going in, but letting them have free liberty to go in and out at pleasure, as this makes them fearfear. Some of the bait should also, he thinks, be laid at the rat-holes, and a little of it scattered quite up to the traps, and so on to the bridge of each trap, where a handful may be placed. It may also, he thinks, be proper to fix in the traps with the following mixture, for the purpose of enticing the rats into them. Take twenty drops of the oil of rhodium, fix or seven grains of musk, and half an ounce of oil of aniseed; put them in a small phial, and make it well before using; then dip a piece of twisted paper or rag in the mixture, and rub each end of the trap with it; if a box trap, and put two or three drops on the bridge, leaving the paper or rag in the trap. Of whatever kind the trap is, it should be scented; but once in a twelvemonth will be sufficient. Then throw some chaff mixed with a little wheat about the bottom of the trap, in order to deceive the rats; for they are very fagacious, and will not enter a suspicious place. This will be necessary to be done only at the first time of setting the traps; for, after some rats have been caught and have watered and dungen in them, rats will enter boldly when they find others have been there before them; do not, therefore, wash or clean out the trap, as some people do before they let it again, but let the dung and urine remain in it. Keep the places where the traps are set as private as possible; and when they are set for catching, mix no bread with the bait, as the rats will, in that case be apt, to carry it away.

And it is useful, this writer remarks, when the holes are found quiet, and that no rats use them, to stop them up with the following composition. Take a pint of common tar, half an ounce of pearl-ashes, an ounce of oil of vitriol, and a good handful of common salt, mix them all well together in an old pan or pot. Take some pieces of paper, and lay some of the above mixture very thick on them; then stop the holes well up with them, and build up the mouth of the holes with brick or stone, and mortar; if this be properly done, rats will, he affirms, no more approach these while either small or tafe remains in the composition.

But with a view to destroy rats in places where traps cannot be set, it is recommended to take a quart of the above bait, then to rap into it three nuts of nux vomica, and add a quarter of a pound of crumb of bread, if there was none before; mix them all well together, and lay it into the mouth of their holes, and in different places where they frequent; but first give them of the bait without nux vomica, for three or four succeeding nights; and when they find it agree with them, they will eat that mixed with the nut with greediness.

However, as it is frequently found that rats are very troublesome in fowars and drains, in such cafes arsenic may be ufed with succese in the following manner. Take some dead rats, and having put some white arsenic, finely powdered, into an old pepper-box, shake a quantity of it
on the fore-parts of the dead rats, and put them down in the holes, or avenues, by the sides of the fewers at which they come in; this puts a stop to the live ones coming any further: for when they perceive the arsenic, they will retire immediately; whereas, if they were put down without the arsenic, the live ones would eat them.

It is by means of arsenic, notwithstanding the above observations, that the most certain method of destroying these troublesome vermin, (provided they can be made to eat it,) takes place; which we have found to answer best, when it is prepared by being finely levigated, and mixed up with very strong old cheese and oatmeal.

In a note in the Agricultural Survey of Lancashire, it is stated, that it is greatly to be lamented that Mr. Heathcote's method of destroying rats and mice is not generally known and practiced; if it were, there would be a total extermination of those obnoxious and destructive animals; for in one night he totally destroys them (where he is employed), be they ever so numerous, as can be well attested by hundreds in the neighbourhood of Osmolke, who have employed him. And it is added, that the composition he makes of he puts in their holes and burrows, and from the small quantity he utes, it is astonishing it should have such an effect: it will keep good two years. It is also stated, that a farmer recommends, for the destruction of rats, one ounce of pounded quick-lime to four ounces of tallow cake, to be beaten together and made into balls, and placed in their runs, which has cleared many buildings. But it has been proved by experience, is said, that an ounce of aerated barytes finely powdered, mixed with the tallow, in place of lime, is more effectual. And it has been remarked by the author of Phytologia, with the view of destroying the water-rats, that they posses some kind of ingenuity similar to the beaver in the construction of their houses near the brinks of rivers and pools; which have two apertures, one above ground amongst the grass, and the other beneath the surface of the water; and unless they can hide their upper opening amid weeds, or grass, they forsake the situation. Thus, if a rim, three or four feet in breadth, round a fish-pond be kept so low as to raise only two, three, or four inches above the level of the water; and if this be kept clean from high grass or weeds, the rats will desert the pond.

But after all, it is probable that this highly destructive animal, and great pest to the farmer, might be more readily exterminated by parishes uniting for the purpose, and raiuing certain sums of money to be applied in this way, under the direction of a proper person who is fully acquainted with the buñfins.

In many grain and other districts in the kingdom these animals prevail very much, especially the grey kind, particularly in all those where there are no regular raised fladdles or Islands for the grass to stack upon, which is the case in a great number. The mischief, injury, and destruction of grass which is produced in this way, is scarcely to be calculated; and they are besides very mischievous, troublesome, and inconvenient in several others; so that they should be every where exterminated as much as possible. And in corn c œ r t s, fladdles or fladdles should every where be provided in order to prevent mischief being done by them. See Vermin, and Stand, Corn.

Rat, Mountain. See Marmot Talpinus, &c.
Rat, Myk. See Mus Zikshius.

Rat, Norway or brown, Mus Norvegicus, (Mus deumanus) is a rat whole head, back, and sides are of a light brown colour, mixed with tawny and ash-colour; the breast and belly are of a dirty white; the feet naked, and of a dirty flesh-colour; the fore-feet are furnished with four toes, and a claw instead of the fifth; the length from the nose to the tail is nine inches, and the tail is of the same length. This animal is more strongly made than the common black rat, or Mus rattus.

This species of rat, which is the same animal that is called in the East Indies a bandiwor, now inhabits most parts of Europe; whether it is supposed to have been brought within the last century, in some of the India ships. It came into Great Britain about 70 or 80 years ago, but has not been known in the neighbourhood of Paris above half that time. They swarm in Petersburg, and are known in Prussia; but have not yet reached the opposite side of the Baltic, as Linnæus takes no notice of this species. There were probably the species Caspius of Eliean, which made periodical visits in great multitudes to the countries bordering on the Caspian Sea, swarming boldly over the rivers, holding by one another's tails. (Elian. Hist. An. 17. cap. 17.) They burrow, like the water rat, on the sides of ponds and ditches; swim and dive well; live on grain and fruits, but will destroy poultry and game; increase fast, producing from fourteen to eighteen young at a time; are very bold and fierce; will turn, when closely pursued, and fasten on the neck or hand that offers to strike them; they have destroyed the common black rat in most places; they inhabit the fields part of the year, but migrate in great numbers into houses, and do much mischief. The bite of these rats is not only severe but dangerous; the wound being immediately attended with a great swelling, and healing very slowly. Pennant. See Mus Decumanus.

Rat, Norway, is also a name given by some writers to the lemming, or fable mouse. See Mus Lemmus, and Sable Mouse.

Rat, Water. See Mus Amphibius.

Rat, in the Sea Language, is used to express a part of the sea, where there are rapid and dangerous currents, or counter-currents.

Rat-Goof, in Ornithology, the name of a small species of wild goose, common in some of the northern counties of England.

Rat-Tails, in the Manager. See Arrets.

Rat-Tailed. A horse is thus called that has no hair upon his tail.

Rat-Tailed Worms, in Natural History, a species of fly-worms with long tails, resembling those of rats, whence they have their name. They are of several sizes, and found also in different places, but all change into two-winged flies, having very much the resemblance of beer, and commonly called beetles. See Drone-Fly.

Rat, Cape, in Geography, a cape of Africa, in the Red Sea. N. lat. 14° 55'.

Rat Island, a small island in Milford Haven.—Also, an island in the Red Sea. N. lat. 14° 55'.—Also, a small island in the East Indian sea, near the W. coast of Sumatra. S. lat. 3° 57'. E. long. 101° 55'.—Also, a small Island in the Mergui Archipelago, S.W. of Olive Island.

Rata pro Rata. See Pro rate.
Onrando pro Rata porionis. See ONERANDO.
RATAFIA, a fine spirituous liquor, prepared from the kernels, &c. of several kinds of fruits, particularly of cherries and apricots.

Ratafia of cherries is prepared by bruising the cherries, and putting them into a vessel in which brandy has been long kept;
...viz. either by boiling the apricots in white wine, adding to the liquor an equal quantity of brandy, with sugar, cinnamon, mace, and the kernels of apricots; infusing the whole for eight or ten days; then straining the liquor, and putting it up for use; or else by infusing the apricots, cut in pieces, in brandy, for a day or two; palling it through a straining-bag, and then putting in the usual ingredients.

**RATAN**, in Geography, a small island on the W. side of the gulf of Bothnia. N. lat. 63° 58'. E. long. 20° 39'.

**RATCH**, or **RASH**, in Clock Work, a sort of wheel having twelve fangs, which serve to lift up the detents every hour, to make the clock strike.

**RATCHETS**, in a Watch, are the small teeth at the bottom of the fusee, or barrel, which float in winding up.

**RATCHIN LOPA**, in Geography, a large lake of Thibet. N. lat. 30° 43'. E. long. 82° 27'.

**RATCLIFF**, a town of America, in Maryland; 22 miles S. of Salisbury.

**RATE**, a standard or proportion, by which either the quantity or value of a thing is adjusted.

The rates of bread, &c. in London, are fixed by authority. See **Aisle of Bread**.

The rate of interest, as now established by law in England, is five per cent. The rate of interest in Italy, is three per cent.; in Sweden, six; in France, five; in Spain, ten; in Barbadoes, ten; in Ireland, twelve; in Turkey, twenty. Low rates of interest advance the prices of land.

The rates or fares of hackney-coachmen, chairmen, and watermen, are fixed by act of parliament. See **Hackle Coaches**, &c.

The rates of exchange, factorship, &c. are different. See **Exchange, Factorage**, &c.

**Rate of a Ship of War**, is its order, degree, or distinction, as to magnitude, burden, force, &c.

The British fleet is accordingly distributed into fix rates, exclusive of the inferior vessels that usually attend on naval armament; as sloops of war, armed ships, bomb-ketches, fire-ships, and cutters or schooners, commanded by lieutenants.

Ships of the **first** rate mount a hundred cannon, and some more, having forty-two-pounders on the lower deck, twenty-four-pounders on the middle deck, twelve-pounders on the upper deck, and fix-pounders on the quarter-deck and forecastle. They are manned with eight hundred and fifty men, including their officers, lieutenants, and marines, and servants.

In general, the ships of every rate, besides the captain, have the master, the boatman, the gunner, the chaplain, the purser, the surgeon, and the carpenter; all of whom, except the chaplain, have their mates or assistants, in which are composed the said officers, the master at arms, the armourer, the captain's clerk, the gunsmith, &c. The number of other officers is always in proportion to the rate of the ship. Thus, a first rate has six lieutenants, fix master's mates, twenty-four midshipmen, and five surgeon's mates, who are considered as gentlemen; besides the following petty officers: quarter-masters, and their mates, fourteen; boatman's mates, and yeomen, eight; gunner's mates and assistants, fix; quarter-gunners, twenty-five; Carpenter's mates, two, besides fourteen assistants; with one steward, and steward's mate to the purser.

Ships of the **second** rate carry ninety-eight and ninety gun upon three decks; of which those on the lower battery are thirty-two-pounders; those on the middle, eighteen-pounders; on the upper deck, twelve-pounders; and those on the quarter-deck, six-pounders, which usually amount to four or fix. Their complement of men is feventy-two and fifty, in which there are fix lieutenants, four master's mates, twenty-four midshipmen, and four surgeon's mates, fourteen quarter-masters and their mates, eight boatman's mates and yeomen, fix gunner's mates and yeomen, with twenty-two quarter-gunners, two carpenter's mates, with ten assistants, and one steward and steward's mate.

Ships of the **third** rate carry from sixty-four to eighty cannon, which are thirty-two, eighteen, and nine-pounders. The eighty-gun ships, however, begin to lose their repute, and give way to those of seventy-four, seventy, &c. which have only two whole batteries; whereas the former have three, with twenty-eight guns planted on each; the cannon of their upper deck being the same as those on the quarter-deck and forecastle of the latter, which are nine-pounders. The complement in a seventy-four is fix hundred and fifty; and in a sixty-four, five hundred men: having in peace, four lieutenants, but in war, five; and when an admiral is aboard, fix. They have three master's mates, fifteen midshipmen, three surgeon's mates, ten quarter-masters and their mates, five boatman's mates and yeomen, four gunner's mates and yeomen, with eighteen quarter-gunners, one carpenter's mate with eight assistants, and one steward and steward's mate under the purser.

Ships of the **fourth** rate mount from fifty to sixty guns, upon two decks and the quarter-deck. The lower tier is composed of twenty-four-pounders; the upper tier of twelve-pounders; and the cannon on the quarter-deck and forecastle are six-pounders. The complement of a fifty-gun ship is three hundred and fifty men, in which there are three lieutenants, two master's mates, ten midshipmen, two surgeon's mates, eight quarter-masters and their mates, four boatman's mates and yeomen, one gunner's mate and one yeoman, with twelve quarter-gunners, one carpenter's mate and fix assistants, and a steward and steward's mate.

All vessels of war under the fourth rate, are usually comprehended under the general name of frigates, and never appear in the line of battle. They are divided into the **fifth** and **sixth** rates, the former mounting from forty to thirty-two guns, and the latter from twenty-eight to twenty. The largest of the fifth rate have two decks of cannon, the lower battery being of eighteen-pounders, and that of the upper deck of nine-pounders; but those of thirty-six and thirty-two guns have only one complete deck of guns, mounting twelve-pounders, besides the quarter-deck and forecastle, which carry fix-pounders. The complement of a ship of forty-four guns is two hundred and eighty men; that of a frigate of thirty-six guns, two hundred and forty men. The frigate has three, and the second two lieutenants; and both have two master's mates, fix midshipmen, two surgeon's mates, fix quarter-masters and their mates, two boatman's mates and one yeoman, one gunner's mate and one yeoman, with ten or eleven quarter-gunners, and one purser's steward.

Frigates of the **sixth** rate carry nine-pounders; those of twenty-eight guns having three-pounders on their quarter-deck, with two hundred men for their crew; and those of twenty-four, one hundred and sixty men: the former has two lieutenants; the latter, one; and both have two master's mates, four midshipmen, one surgeon's mate, four quarter-masters and their mates, one boatman's mate and one yeoman, one gunner's mate and one yeoman, with six or seven quarter-gunners, and one purser's steward.
The floops of war carry from eighteen to eight cannon; the largest of which have fix-pounders; and the smallest, six, those of eight or ten guns, four-pounders. Their officers are generally the same as in the sixth rates, with little variation; and their complements of men are from one hundred and twenty to sixty, in proportion to their force or magnitude.

Bomb-veffes are on the same establishment as floops; but fire-ships and hospital-ships are on that of fifth rates. If the dimensions of all ships of the same rate were equal, it would be easy to collect them into one point of view in a table; but as there is no irrevocable rule for the general dimensions, we shall select those of some of a late construction in each rate.

Ships of one hundred guns, and above, and downwards to sixty-four, are termed ships of the line.

Ships of the line, frigates, and royal yachts, are commanded by post-captains; floops of war, bomb-ships, fire-ships, armed ships, floore-ships, and armed en flutes, under fifty guns, by commanders; schooners, cutters, &c. by lieutenants; and ships occasionally by masters; and small craft by midshipmen, who have passed for lieutenants.

Ships of the second rate, and those of the third, which have three decks, carry their sails remarkably well, and labour very little at sea. They are excellent in a general action, or in cannonading a fortres. Those of the third rate, which have two tiers, are fit for the line of battle, to lead the convoys and squadrons of ships of war in action; and, in general, to suit the different exigences of the naval service. The fourth rates may be employed on the same occasions as the third rates; and may be also defined for service among the foreign colonies, or on expeditions of great dilance; since their veffes are usually excellent for keeping and maintaining the sea. Veffes of the fifth rate are too weak to suffer the shock of a line of battle; but they may be defined to lead the convoys of merchant ships, to protect the commerce in the colonies, to cruize in different stations, to accompany squadrons, or be sent express with necessary intelligence and orders. The same may be observed of the fifth rates.

The frigates which mount from twenty-eight to thirty-eight guns upon one deck, with the quarter-deck, are extremely proper for cruising against privateers, or for short expeditions, being light, long, and usually excellent failures.

RATHENAUL, or Ratemao, a town of the middle mark of Brandenburg, on the Havel; 38 miles W. of Berlin. N. lat. 52° 38'. E. long. 12° 32'.

RATHER, or Nether, a river of England, which runs into the Lune, four miles N. of Kirkby Lonsdale, in the county of Westmoreland.

RATHERIUS, in Biography, a very learned prelate in the tenth century, commenced his ecclesiastical career by embracing a monastic life at the abbey of Lobbes, or Laubes, in Flanders. Here he distinguished himself by his abilities and acquirements. In the year 928, after Hildepin had been driven out of the see of Liege, he accompanied him into Italy; and in 931 he was, by the express order of the pope, put in possession of the see of Verona. As, however, this was in direct hostility to the king of the country, he was exposed to much persecution, and at length banished from Italy. After spending five years in exile, he returned with the hope of regaining his bishopric; but he was unsuccessful, and was ordered to withdraw. He obeyed, and retired into Provence; from this place he went to the abbey of Lobbes, where the recollection of the honour, which he had formerly reflected on the establishment, figured him a welcome reception. Shortly after this, he was sent for by the emperor Otto, who placed him near the perfum of his brother Bruno. This prince, having been made archbishop of Cologne in the year 953, presented Ratherius to the bishopric of Liege; from which, however, he was driven in about two years. As the emperor Otto was at this time in Italy, our prelate made an effort to recover his former see of Verona. Accordingly he laid his case before a synod assembled at Pavia, which passed a decree that he should be re-established in that bishopric. His peace was soon interrupted by controversies with the clergy, who could not endure his reproofs of their irregularities and corruptions; till at length they became so irksome to him, that he determined to take his final leave of Italy. He accordingly went to France, where he purchased some estates, and obtained the abbies of St. Amand, Aumout, and of Amay. He died at Namur, about the year 973. His works are numerous, some of which are inserted in father d’Achéry’s “Spicilegium.” They are said to afford evident proofs of great sagacity and judgment, while they breathe throughout an ardent love of virtue. They also shew, that he was much zealous and intrepid in exposing the irregularities and vices of the times, and particularly the corrupt morals of ecclesiastics. Morei. Motheim.

RATHFRILAND, in Geography, a poiltown of the county of Down, Ireland. It is situated on a rising ground, and has four great straight roads leading up to it, and centering in the town. It is on the road to Downpatrick, and much frequented. The neighborhood abounds with granite of a clof texture, and fit for building. On the summit of the hill are the ruins of a castle, formerly one of the residences of the Magennis, lords Iveagh. Rathfriland is 57½ miles N. from Dublin, and 7½ miles N.E. from Newry.

RATHKEALE, a poiltown of Ireland, in the county of Limerick. It is situated on the river Deel, and was formerly a corporation town, and of much more consequence than at present. It has several fairs, one of which for horses is much frequented, as are also its races. In the reign of queen Elizabeth, it sustained an attack of the English army. The ruins of a priory, founded by a person of the name of Harvey, are still remaining. Rathkeale is 108 miles S.W. from Dublin, and 14 miles W.S.W. from Limerick.

RATHLACKEN, a poiltown of the county of Mayo, Ireland, on the sea-coast, nor far from Rathlacken or Ralakin head, and west of the entrance to Killala bay. It is 132 miles W.N.W. from Dublin, and 5 miles N. from Killala.

RATHLIN, Raghill, or Raghey, an island situated between the north coast of Antrim, in Ireland, and Scotland, and confidered as belonging to the former. It is about five miles in length, and three quarters of a mile in breadth, being bent in an angle towards the middle. This angle lies opposite to Ballycastle, and forms a tolerable bay, called Church bay; but in a westerly wind, though the anchorage is good, few vessels can ride it out, from the swell along the coast. The number of plantation acres is about 2000, which support a population of about 130 or 140 families, amounting to about 700 persons. The cultivated land is kindly enough, and produces excellent barley. But kelp is the great source of wealth to this island, 100 tons of which have been exported from it in one year. The horses, as well as the sheep, are small, but serviceable; and the black cattle are not large, though they do well when brought to the main land, and better for. The inhabitants are a little hardy, honest race of people, much attached to their own island, and regarding Ireland as a foreign country. The monuments of antiquity are small tumuli, in one of which, when opened, a stone coffin was found, beside which an earthen vessel stood. Within the tumuli lay a considerable number of human bones, which might have been the remains of more ignoble men than the person whose remains the coffin covered. Brazen swords and spear-heads have also been found. The remains of a fortress are visible, where Robert Bruce is said to have defended himself for some time, when obliged to fly from his country. N. lat. 55° 20'. W. long. 6° 0'.

RATHMANSFORD, a town of Silezia, in the principality of Neisse; 4 miles N. N.W. of Weißenau.

RATHOWEN, a poiltown of the county of Wexmuth, Ireland, near the borders of Longford; 48 miles W.N.W. from Dublin.

RATHSCHACH, or Radesche, a town of the duchy of Carniola, on the Save; 9 miles W.N.W. of Grefeld.

RATHSPRÆSENTGERS, in Commerce, silver coins of Aix-la-Chapelle, being double, single, or half pieces of 22, 16, and 8 marks. By the aßay, the rathspresentger is worse than the English flandard of 11 oz. 2 dwts., by 4 oz. 2 dwts. Its weight is 4 dwts. 1½ gr.; its content in pure silver 56.9 grs.; and its value in silver 8. It is of the double of the same is worse by 2 oz. 15 dwts.; its weight 6 dwts. 23½ grs.; its content in pure silver 116.3 grs.; and its value in silver 15½. This coin bears on one side an eagle within a circle, marked 16 on his breast, (32 on the double piece,) and within another circle the legend, REGNUM CURA PRINCIPIIS PRIMA; and next the edge, URBIS AQUENSIS. URBIS REGALIS. REGNI SEDES; on the other side, or reverse, an altar, with two swords and a crown over it, on the double piece; but on the single, a crown and the date within a circle: the legend on both is LUCUS CESAREA CORONATIONIS; Caesar being a general title for the emperor. Kelly’s Un. Cambit.

RATI, in Geography, a small island in the Grecian Archipelago, near the S. coast of Nicaria.

RATIBOR, a town of Silezia, in a principality of its name, on the Oder, which here becomes navigable; 70 miles
miles S.E. of Breslau. N. lat. 50°, E. long. 18° 51'. The principality is bounded N. by the principality of Oppeln, on the E. by Poland, on the S. by Telechen, and on the W. by the principality of Jagendorf. Its soil is better than that of Oppeln, as it produces a sufficient supply of wheat, rye, and barley, with fruits; and besides, it has also good pasture grounds. Its only river is the Oder, which passes through its western part; but it is abundantly watered in all its parts with streams, ponds, and lakes. It contains only three cities, and the inhabitants are universally Polish. It became a principality in 1288, and about 200 years afterward it was united to Oppeln, from which it has never been separated.

RATIFICATION, Ratification, an act, approving of, and confirming, something done by another, in our name.

A treaty of peace is never secure till the princes have ratified it.

All procuration imports a promise of ratifying and approving what is done by the proxy, or procurator: after treating with a procurator, agent, factor, &c. a ratification is frequently necessary on the part of his principal.

Ratification is particularly used, in our Laws, for the confirmation of a clerk in a benefice, prebend, &c. formerly given him by the bishop, &c. where the right of patronage is doubted to be in the king.

Ratification is also used for an act confirming something we ourselves have done in our own name.

An execution, by a major, of an act paid in his minority, is equivalent to a ratification.

RATING. See Ratting.

RATINGEN, or Rattingen, in Geography, a town of the duchy of Berg: 4 miles N.E. of Duffeldorp. N. lat. 51° 15'. E. long. 6° 47'.

RATINO, a town of Naples, in the county of Molife; 6 miles S.E. of Molife.

Ratio, in Arithmetic and Geometry, that relation of homogeneous things, which determines the quantity of one from the quantity of another, without the intervention of any third.

The homogeneous things, thus compared, we call the terms of the ratio; particularly that referred to the other, we call the antecedent; and that to which the other is referred, the consequent.

Thus, when we consider one quantity by comparing it with another, to see what magnitude it has in comparison of that other; the magnitude this quantity is found to have in comparison with it, is called the ratio of this quantity to that; which some think would be better expressed by the word comparison.

Euclid defines ratio by a mutual relation of two magnitudes of the same kind in respect of quantity. But this definition is found defective; there being other relations of magnitudes which are constant, yet are not included in the number of ratios: such as that of the right line, to the line of the complement in trigonometry.

Hobbes endeavoured to improve Euclid's definition of ratio, but without success; for in defining it, as he does, by the relation of magnitude to magnitude, his definition has not only the same defect with Euclid's, but in determining the particular kind of relation; but it has this farther, that it does not express the kind of magnitudes which may have a ratio to one another.

Ratio is frequently confounded, though very improperly, with proportion. Proportion, in effect, is an identity or similitude of two ratios.

Thus, if the quantity A be triple the quantity B; the relation of A to B, i.e. of 3 to 1, is called the ratio of A to B. If two other quantities, C, D, have the same ratio to another that A and B have, i.e. be triple one another, this equality of ratio constitutes proportion; and the four quantities A : B :: C : D, are in proportion, or proportional to one another.

So that ratio exists between two terms; proportion requires more.

There is a twofold comparison of numbers: by the first, we find how much they differ, i.e. by how many units the antecedent exceeds, or comes short of, the consequent.

This difference is called the arithmetical ratio, or exponent of the arithmetical relation or habit of the two numbers. Thus, if 5 and 7 be compared, their arithmetical ratio is 2.

By the second comparison, we find how oft the antecedent contains, or is contained in, the consequent; i.e. as before, what part of the greater is equal to the less.

This ratio, being common to all quantity, may be called ratio in the general, or by way of eminence: but is usually called geometrical ratio; because expressed, in geometry, by a line, though it cannot be expressed by any number.

Modern authors distinguish ratio, with regard to quantity in the general, into rational and irrational.

Ratio, Rational, is that which is as one rational number to another; e. gr. as 2 to 4.

Ratio, Irrational, is that which cannot be expressed by rational numbers.

Suppose, for an illustration, two quantities, A and B; and let A be less than B. If A be subtracted as often as it can be from B, e. gr. five times, there will either be left nothing, or something. In the former case, A will be to B, as 1 to 5; that is, A is contained in B five times; or A = B. The ratio here, therefore, is rational.

In the latter case, either there is a term, which, being subtracted certain times from A, e. gr. 3 times, and likewise from B, e. gr. 7 times, leaves nothing; or there is no such part: if the former, A will be to B as 3 to 7, or A = 3/7 B; and therefore the ratio, rational. If the latter, the ratio of A to B, i.e. what part A is of B, cannot be expressed by rational numbers; nor any other way than either by lines, or by infinite approaching series.

The exponent of a geometrical ratio is the quotient arising from the division of the antecedent by the consequent. Thus, the exponent of the ratio of 3 to 2, is 1+1; that of the ratio of 2 to 3, is 2/3; for when the less term is the antecedent, the ratio, or rather the exponent, is a proper fraction. Hence the fraction 2/3 = 3/4. If the consequent be unity, the antecedent itself is the exponent of the ratio: thus, the exponent of 4 to 1, is 4. See Exponent.

If two quantities be compared, without the intervention of a third; either the one is equal to the other, or unequal: hence, the ratio is either of equality or inequality. If the terms of the ratio be unequal, either the less is referred to the greater, or the greater to the less: that is, either the less is to the greater, as a part to the whole, or the greater to the less, as the whole to a part. The ratio, therefore, determines how often the less is contained in the greater, or how often the greater contains the less; i.e. to what part of the greater the less is equal.

The following distinctions of ratios are sometimes found in early authors.

The ratio which the greater term has to the less, e. gr. 6 to 3, is called the ratio of the greater inequality: the ratio which the less term has to the greater, e. gr. 3 to 6, is called the ratio of the lesser inequality.

This ratio corresponds to quantity in the general, or is admitted
RATIO.

admitted of by all kinds of quantities, discrete or continued, commensurable or incommensurable; but discrete quantity, or number, does likewise admit of another ratio.

If the less term of a ratio be an aliquot part of the greater, the ratio of the greater inequality is said to be multiplex, multiple; and the ratio of the less inequality, submultiplex.

Particularly, in the first cafe, if the exponent be 2, the ratio is called duple; if 3, triple, &c. In the second case, if the exponent be ½, the ratio is called subduple; if ¼, subtripple, &c.

E. gr. 6 to 2 is in a triple ratio; because 6 contains two thrice. On the contrary, 2 to 6 is a subtriple ratio; because 2 is the third part of 6.

If the greater term contains the lefs once, and over and above an aliquot part of the same; the ratio of the greater inequality is called superparticular, and the ratio of the less subsuperparticular.

Particularly, in the first case, if the exponent be ½, it is called sesquialterate; if ¼, sesquiquaterial, &c. In the other, if the exponent be ¼, the ratio is called subsesquialterate; if ⅛, subsesquiquaterial, &c.

E. gr. 3 to 2 is in a sesquialterate ratio; 2 to 3 in a subsesquialterate.

If the greater term contains the lefs once, and over and above several aliquot parts; the ratio of the greater inequality is called superparticular; that of the less inequality subsuperparticular.

Particularly, in the former case, if the exponent be ½, the ratio is called superbipartions tertius; if the exponent be ⅘, superbipartitions quartis; if ⅓, superquadripartitions septimae, &c. In the latter case, if the exponent be ¼, the ratio is called subsuperbipartitions tertius; if ⅛, subsuperbipartitions quartis; if ⅛, subsuperquadripartitions septimae.

E. gr. the ratio of 5 to 3 is superbipartitions tertius; that of 3 to 5, subsuperbipartitions tertius.

If the greater term contains the lefs several times, and, besides, some quota part of the same; the ratio of the greater inequality is called multiplex superparticular; and the ratio of the less inequality, submultiplex subsuperparticular.

Particularly, in the former case, if the exponent be ½, the ratio is called dupla sesquialterate; if ¾, triples sesquiquarteris, &c. In the latter case, if the exponent be ⅗, the ratio is called subdupla sesquialterate; if ⅘, subtripula sesquiquateris, &c.

E. gr. the ratio of 16 to 5 is tripula sesquiquarissima; that of 4 to 9, subdupla sesquiquarissa.

Lastly, if the greater term contains the lefs several times, and several aliquot parts of it besides; the ratio of the greater inequality is called multiplex superparticular; that of the less inequality, submultiplex subsuperparticular.

Particularly, in the greater inequality, if the exponent be ½, the ratio is called dupla superbipartions tertius; if ⅓, triples superbipartitions quartis; if ⅘, superquadripartitions septimae, &c. In the latter case, if the exponent be ¼, the ratio is called subdupla superbipartions tertius; if ⅘, subtripula superquadripartitions septimae, &c.

E. gr. the ratio of 25 to 7 is tripula superquadripartitions septimae; that of 3 to 8, subdupla superquadripartitions tertius.

These are the various kinds of rational ratios; the names of which, though they occur but rarely among the modern writers (for in lieu of them they use the smallest terms of the ratios, e. gr. for duple 2:1, for sesquialterate 3:2); yet are they absolutely necessary to such as converse with the ancient authors.

Clavis observes, that the exponents denominate the ratios of the greater inequality, both in deed and name; but the ratios of the less inequality, only in deed, not in name; but it is easy finding the name in thefe, if you divide the denominator of the exponent by the numerator.

E. gr. if the exponent be ⅗, then 5:8 = 1¾; whence it appears, the ratio is called subsuperparticular quintus. As to the names of irrational ratios, nobody ever attempted them.

Some, or identic ratios, are those where antecedents have an equal respect to their consequents, i.e. whole antecedents divided by their consequents, give equal exponents. And hence may the identity of irrational ratios be conceived.

Hence, first, as oft as the antecedent of one ratio contains its consequent, or whatever part it contains of its consequent, so oft, or each part of the other consequent does the antecedent of the other ratio contain: or, as oft as the antecedent of the one is contained in its consequent, so oft is the antecedent of the other contained in its consequent.

Secondly, if A be to B as C to D; then will A : B :: C : D; or A : B = C : D. The former of which is the usual manner of representing the identity of ratios, the latter is that of the excellent Wolthus; which has the advantage of the former, in that the middle character, =, which denotes the sameness, is identical; i.e. it expresses the relation of the thing represented, which the other, :, does not. See Character.

Two equal ratios, i.e. gr. B : C = D : E, we have already observed, confitute a proportion: of two unequal ratios, e. gr. A : B and C : D; we call A : B the greater, if A : B > C : D; on the contrary, the smaller, if C : D > A : B.

Hence, we express a greater and less ratio thus: e. gr. 6 to 3 has a greater ratio than 5 to 4; for, 6:3 ( = 2) > 5:4 ( = 1¾). But 3 to 6 has a less ratio than 4 to 5; for ¾ > ⅘. Compound ratio is that made up of two or more ratios, which the fætum of the antecedents of two or more ratios has to the fætum of their consequents. Thus, 6 to 7:2 is in a ratio compounded of 2 to 6, and 3 to 12.

Particularly if it be compounded of two, it is called a duplicate ratio; if of three, a triplicate; if of four, quadruplicate; and, in the general, multiplicate, if it be composed of several similar ratios. Thus 4¾ : 3 is a duplicate ratio of 4 : 1 and 12 : 3.

Ratio, Additive. See Additive.

Ratio, Alternare. See Alternate.

Ratio, Ordinate. See Ordinate.

Ratio Modularris and Modulus, were terms introduced into use by Cotes, but more modern authors do not ufe them always in the same fene: according to Cotes, the modulus in logarithms is that number which connects any fystem of logarithms with the hyperbolic fystem, or that number by which the hyperbolic number of a logarithm may be multiplied, or by the reciprocal of which it must be divided, in order to transform it to another fystem; and this modulus is, therefore, always the reciprocal of the hyperbolic logarithm of the radix of that fystem to which the modulus belongs.

This is what Cotes calls the modulus, to whom we owe the introduction of the term; and the reciprocal of it he calls the ratio modularris: but some modern authors, as Lagrange, &c. ufe: the term modulus to denote the ratio modularris of Cotes.

The modulus of the hyperbolic fystem is 1, this being the reciprocal of the hyperbolic logarithm of 2·71828182, the radix of this fystem; and the modulus of the common logarithm
logarithmic systenm is \( \log_{10} 960 \approx 2.9429 \), which is the reciprocal of \( 2.94289759 \), the hyperbolic logarithm of 10, the radix of this system.

It is shewn under the article Logarithms, that

\[
\log a = \frac{(a - 1) - \frac{1}{2} (a - 1)^2 + \frac{1}{3} (a - 1)^3, \text{ &c.}}{r - 1 - \frac{1}{2} (r - 1)^2 + \frac{1}{3} (r - 1)^3, \text{ &c.}}
\]

where \( r \) is the radix, and may be assumed at pleasure, and the reciprocal of this whole denominator is called the modulus. In the hyperbolic system the whole denominator is assumed 1, which makes \( r = 2.7182818 \); and in the common system \( r \) is assumed 10, and the whole series becomes

\[
\log a = \frac{(a - 1) - \frac{1}{2} (a - 1)^2 + \frac{1}{3} (a - 1)^3, \text{ &c.}}{r - 1 - \frac{1}{2} (r - 1)^2 + \frac{1}{3} (r - 1)^3, \text{ &c.}}
\]

hyp. \( a = (a - 1) - \frac{1}{2} (a - 1)^2 + \frac{1}{3} (a - 1)^3, \text{ &c.} \)

if \( r \) be any other

hyp. \( a = (r - 1) - \frac{1}{2} (r - 1)^2 + \frac{1}{3} (r - 1)^3, \text{ &c.} \)

whatever be the value of \( r \); therefore, in every system, the modulus is the reciprocal of hyp. \( a \) of the radix. See Logarithms.

**RATIO.**

**Denominator of a.** See Denominator.

**RATIO, Properties of a.** Ratios similar to the fame two are also similar to one another; and those similar to similar, are also similar to one another. If \( a : b :: c : d \); then, inversely, \( b : a :: d : c \).

1. Similar parts \( p \) and \( q \) have the same ratio to the wholes \( T \) and \( t \); and if the wholes have the fame ratio, the parts are similar.

2. If \( a : b :: c : d \); then, alternately, \( a : c :: b : d \). And hence, if \( b = d, a = c \); hence, also, if \( a : b :: c : d \); and \( a : f :: c : g \); we shall have \( b : f :: d : g \). Hence, again, if \( a : b :: c : d \); and \( f : a :: g : c \); we shall have \( f : b :: g : d \).

3. Those things which have the same ratio to the fame, or equal things, are equal; and vice versa.

4. If you multiply any quantities, as \( a \) and \( b \), by the fame, or equal quantities, their products \( d \) and \( e \) will be to each other as \( a \) and \( b \).

5. If you divide any quantities, as \( a \) and \( b \), by the same, or equal quantities, the quotients \( f \) and \( g \) will be to each other as \( a \) and \( b \).

6. The exponent of a compound ratio is equal to the product of the exponents of the simple ratios.

7. If you divide either the antecedents or the consequents of similar ratios, \( a : b, c : d \), by the same \( e \); in the former case, the quotients \( f \) and \( g \) will have the same ratio to the consequents \( b \) and \( d \); in the latter, the antecedents \( a \) and \( b \) will have the same ratio to the quotients \( h \) and \( k \).

8. If there be several quantities in the same continued ratio \( a, b, c, d, e, \text{ &c.} \); the first \( a \) is to the third \( c \), in a duplicate ratio; to the fourth \( d \), in a triplicate; to the fifth \( e \), in a quadruplicate, \&c. ratio of the ratio of the first \( a \), to the second \( b \).

9. If there be any series of quantities in the same ratio, \( a, b, c, d, e, f, \text{ &c.} \); the ratio of the first \( a \) to the last \( f \) is compounded of the intermediate ratios \( a : b, b : c, c : d, d : e, e : f, \text{ &c.} \).

10. Ratios compounded of ratios, of which each is equal to each other, are equal among themselves. Thus the ratios

\[
90 : 3 :: 560 : 32, \text{ compounded of } 6 : 3 :: 4 : 2, \text{ and } 3 : 1 :: 12 : 4; \text{ and } 5 : 1 :: 20 : 4.
\]

For other properties of similar or equal ratios, see Proportion.
verging fractions will be \( \frac{bc + 1}{a}, \frac{bc + 1}{b}, \frac{(bc + 1)d + b}{(ab + 1)c + a}, \) &c. which will be found to agree with the preceding rule; and these fractions will be alternately greater and less than that proposed, which will be the last of the series.

Let us illustrate this rule by an example. Required a series of converging fractions towards \( \frac{314159}{100000} \), which is the fraction commonly employed for expressing the ratio of the diameter to the circumference of a circle.

**Operation by Division.**

\[
\begin{array}{c}
\frac{314159}{100000} \\
\frac{14159}{100000} \\
\frac{887}{14159} \\
\frac{13305}{887} \\
\frac{854}{13305} \\
\frac{29}{854} \\
\frac{1}{29} \\
\frac{4}{28} \\
\frac{1}{4} \\
\end{array}
\]

Having thus obtained our quotients, the several fractions will be easily formed by the preceding rule; thus,

\[
\begin{array}{ccccccc}
3 & 7 & 15 & 25 & 1 & 7 & 4 \\
3 & 22 & 333 & 355 & 9208 & 9563 & 76149 \\
7 & 7 & 106 & 113 & 3044 & 2423 & 100000 \\
\end{array}
\]

the last of which is the same as the original fraction. These fractions are formed according to the preceding rule, which will be understood from one example; thus, the fifth fraction is formed from the two preceding fractions as follows:

\[355 \times 25 + 333 = 9208 \text{ numerator,}
\]

\[113 \times 25 + 106 = 2931 \text{ denominator,}
\]

and all the others are obtained in the same manner.

Each of these fractions represents an approximate ratio towards the original one, and each of them nearer than any preceding fraction in the series, and nearer than any fraction expressed in less numbers, or than any fraction having a less denominator than the succeeding fractions.

Thus, \( \frac{3}{7} \) is a nearer approximation than any fraction whose denominator is less than \( \frac{3}{1} \), and \( \frac{355}{113} \) nearer than any fraction whose denominator is less than 2931; &c.

Our original fraction exhibited the ratio usually employed to denote the ratio of the diameter to the circumference of a circle, and amongst our approximations we find some of those commonly employed by former writers; as \( \frac{22}{7} \), being that given by Archimedes; \( \frac{160}{53} \), which is another ratio formerly used; also \( \frac{113}{355} \), being that invented by Peter Metius. Each of these ratios is alternately too small and too great, to express the ratio of the diameter to the circumference of the circle. Thus, \( \frac{1}{7} \) is too small a ratio, \( \frac{7}{22} \) too great, \( \frac{106}{333} \) too small, and \( \frac{113}{355} \) too great; and so on.

We may therefore divide the above series into two distinct classes, one of which shall exhibit the ratios all in excess, and the other all in defect, which will stand as follows: viz.

**Ratios in defect.**

\[
\begin{array}{cccc}
3 & 333 & 9208 & 76149 \\
7 & 106 & 2931 & 24239 \\
\end{array}
\]

**Ratios in excess.**

\[
\begin{array}{cccc}
22 & 355 & 9563 & 314159 \\
7 & 113 & 3044 & 100000 \\
\end{array}
\]

And between every two consecutive fractions we may now interpolate as many fractions of the same kind, as is one less than the number of units in the quotients from which it was formed. If we write the first of the above series, with the corresponding quotients above their terms, we shall have

\[
\begin{array}{cccc}
15 & 25 & 7 & 4 \\
3 & 333 & 9208 & 79149 \\
7 & 106 & 2931 & 24239 \\
\end{array}
\]

We may therefore interpolate, between the two first fractions, fourteen others, which will possess the same property as the principal fractions above, viz. of approximating nearer to the true ratio than any other fractions expressed in less terms, but all in defect. Between the second and third we may interpolate twenty-four fractions; and between the third and fourth, six: all of them less than the proposed ratio. But if we take the second series and their corresponding quotients, they will stand thus:

\[
\begin{array}{cccc}
1 & 1 & 4 & 4 \\
22 & 355 & 9563 & 314159 \\
7 & 113 & 3044 & 100000 \\
\end{array}
\]

which shows, that no fraction can here be interpolated either between the first and second, or between the second and third; but there may be three interpolated between the third and fourth, which will, of course, be all in excess. This interpolation is performed as follows: to the numerator and denominator of the least fraction add, once, twice, three times, &c. the numerator and denominator of the principal fraction which interferes between the two, which will form the interpolated fractions required. Thus, because \( \frac{76149}{24239} \) is the principal fraction interpolated between \( \frac{9563}{314159} \) and \( \frac{3044}{100000} \), the intermediate or interpolated fractions will be

\[
\begin{array}{cc}
9563 + 76149 = 85712 & 3044 + 24239 = 27283 \\
9563 + 226149 = 161861 & 3044 + 24239 = 51522 \\
9563 + 376149 = 238010 & 3044 + 34239 = 75761 \\
\end{array}
\]

And
And in the same manner we may interpolate fourteen
fractions between \( \frac{3}{1} \) and \( \frac{333}{106} \); twenty-four between \( \frac{333}{106} \) and \( \frac{268}{293} \); and six between \( \frac{268}{293} \) and \( \frac{16149}{23639} \).

Having thus explained the nature of the operation, we
shall enter lefs into detail in the following example.

Example 2.—According to M de la Caille, the solar year is \( 365 \frac{9}{4} \) \( 5 \) \( 40 \) \( 49 \), and consequently longer by \( 5 \) \( 40 \) \( 49 \) than the common year of 365 days. If this
difference were exactly 6 hours, it would make one day at
the end of four common years: but if we wish to know
exactly at the end of how many years this difference will
produce a certain number of days, we must seek the ratio
between \( 24 \) \( 40 \) \( 49 \) and \( 5 \) \( 40 \) \( 49 \), which we find to be \( \frac{26929}{86400} \).

so that at the end of 86400 common years, we must
intercalate 20929 days, in order to reduce them to tropical
years.

Now as the ratio of \( 86400 \) to \( 20929 \) is expressed in very
high terms, let it be required to find ratios in lower terms,
as near this as possible.

For this purpose, we must perform upon these numbers
the same operations as in the preceding case; thus:

\[
\begin{align*}
20929 & \times 86400 (4 = a) \\
2684 & \times 20929 (7 = b) \\
18788 &
\end{align*}
\]

\[
\begin{align*}
2141 & \times 2684 (1 = e) \\
2141 &
\end{align*}
\]

\[
\begin{align*}
543 & \times 2141 (3 = d) \\
1629 &
\end{align*}
\]

\[
\begin{align*}
512 & \times 543 (1 = e) \\
512 &
\end{align*}
\]

\[
\begin{align*}
31 & \times 512 (16 = f) \\
496 &
\end{align*}
\]

\[
\begin{align*}
16 & \times 31 (1 = g) \\
16 &
\end{align*}
\]

\[
\begin{align*}
15 & \times 16 (1 = h) \\
1 &
\end{align*}
\]

\[
\begin{align*}
15 & \times 15 (1 = h) \\
15 &
\end{align*}
\]

From which quotients we derive the following converging
fractions, \( \frac{4}{1} \), \( \frac{7}{1} \), \( \frac{11}{3} \), \( \frac{16}{1} \), \( \frac{16}{1} \), \( \frac{15}{1} \), \( \frac{15}{1} \).

It appears farther, that as the fractions \( \frac{4}{1} \), \( \frac{29}{7} \), \( \frac{33}{8} \), \( \frac{86400}{20929} \),
are alternately less and greater than the fraction \( \frac{86400}{20929} \), or

\[
\begin{align*}
24 \times 49 = 48 \times 49,
\end{align*}
\]

the intercalation of 1 day in 4 years would be
too much of 7 days in 29 years too little, of 8 days in 33 years too much again, and so on; but each of these
intercalations will be the most exact, that it is possible to make
in the same space of time.

Now if we arrange in two separate series, the fractions
that are less, and those that are greater, than the given
fractions, we may infer or interpolate between certain of
these fractions, as in the preceding examples.

Taking first those fractions that are less than the given
one, and their corresponding quotients, we shall have,

\[
\begin{align*}
1 & \times 15 \\
4 & \times 33 \\
& \times 2865 \\
& \times 86400 \\
1 & \times 89694 \\
& \times 20929 \\
\end{align*}
\]

Hence it appears, that the only interpolation that can be
performed is between the two fractions \( \frac{2865}{694} \) and \( \frac{86400}{20929} \),
which will admit of 14 intermediate fractions; which being
supplied, as in the former example, gives the following
series of converging fractions, each less than the fraction
originally proposed, \( \frac{4}{1} \).

\[
\begin{align*}
\frac{4}{1} & \times 33 \\
\frac{161}{39} & \times 2865 \\
\frac{8434}{694} & \times 2043 \\
\frac{14003}{3392} &
\end{align*}
\]

\[
\begin{align*}
\frac{19572}{10690} & \times 39710 \\
\frac{36729}{7439} & \times 8788 \\
\frac{41848}{5855} & \times 61424 \\
\frac{10137}{14184} & \times 15533 \\
\frac{69533}{86831} & \times 86400 \\
\frac{16882}{19586} & \times 20929 \\
\end{align*}
\]

And as the last fraction is the same as the given fraction, it
is evident that this series cannot be carried farther: hence, if
we choose to admit these intercalations only in which the
error is too much, the simplest and most exact will be those
of 1 day in 4 years, or of 8 days in 33 years, or of 39 in
161 years, and so on.

Let us now consider the decreasing fractions:

\[
\begin{align*}
7 & \times 3 \\
29 & \times 16 \\
& \times 2704 \\
& \times 5569 \\
7 & \times 31 \\
& \times 655 \\
& \times 1349 \\
\end{align*}
\]

Here it appears, that we may place 6 fractions before the
first, 2 between the first and second, 15 between the second
and third; but between the third and fourth no such fraction
can be inserted.

These intercalations being made, we shall have the fol-
lowing series of decreasing fractions, \( \frac{5}{1} \).

\[
\begin{align*}
\frac{5}{1} & \times 9 \\
\frac{13}{2} & \times 17 \\
\frac{21}{3} & \times 25 \\
\frac{29}{4} & \times 6 \\
\frac{59}{5} & \times 65 \\
\frac{2}{7} & \times 128 \\
\frac{289}{8} & \times 450 \\
\frac{7}{15} & \times 31 \\
\frac{70}{10} & \times 109 \\
\frac{611}{148} & \times 933 \\
\frac{1094}{187} & \times 1255 \\
\frac{226}{148} & \times 253 \\
\end{align*}
\]
RATIO.

\[
\begin{array}{ccccccc}
1416 & 1577 & 1738 & 1899 & 2060 \\
343 & 382 & 421 & 460 & 499 \\
2221 & 2382 & 2543 & 2704 & 2865 \\
538 & 577 & 616 & 655 & 1349
\end{array}
\]

which are all less than the proposed fraction, and expressed in less terms; and each of which is nearer than any other fraction that can be expressed in less terms.

Hence we conclude, that if we only attend to the intercalations in which the error is too small, the simplest and most exact are those of 1 day in 5 years, of 2 days in 9 years, of 3 days in 13 years, of 4 days in 17 years, and so on.

In the Gregorian calendar, only 97 days are intercalated in 400 years; but it is evident, from the preceding table, that it would be much more exact to intercalate 109 days in 450 years.

But it must be observed, that in the Gregorian reformation, the determination of the year given by Copernicus was made use of, which is 365² 6² 9² 20³; and substituting this instead of the fraction \( \frac{86400}{29029} \), we shall have \( \frac{86400}{29060} \) rather \( \frac{540}{131} \); whence we may find, by the preceding method, the quotients 4, 8, 5, 3; and from them the principal fractions

\[
\frac{4}{1}, \frac{8}{2}, \frac{5}{3}, \frac{3}{4}, \frac{160}{41}, \frac{540}{131}
\]

which, except the two first, are quite different from those before determined. However, we do not find amongst these fractions \( \frac{400}{97} \), which is that adopted in the Gregorian calendar; and this fraction cannot even be found among the interpolated fractions, which might be inserted in the two series, \( \frac{4}{1}, \frac{169}{41}, \frac{33}{8}, \frac{540}{131} \); for it is evident that it could only be between the last two fractions, between which, because of the number 3, (the corresponding quotient,) there can be but two fractions interpolated, which are \( \frac{202}{49}, \frac{371}{90} \); whence it appears, that it would have been more exact, if, in the Gregorian reformation, they had only intercalated 90 days in the space of 371 years.

If we reduce the fraction \( \frac{400}{37} \), so as to have for its numerator the number 86400, it will become \( \frac{86400}{20052} \) which estimates the tropical year at 365² 6² 9² 12³.

In this case, the Gregorian intercalation would be quite exact; but as observations show that the year is shorter than this by more than 20³, it is evident that, at the end of a certain period of time, we must introduce a new intercalation.

If we adopt the determination of de la Caille, it follows, as the denominator 97 of the above fraction, viz. \( \frac{400}{97} \), lies between the denominators of the fifth and sixth principal fractions already found, that, from what has been said above, the fraction \( \frac{161}{39} \) will be nearer the truth than

\( \frac{400}{97} \). But as astronomers are still divided with regard to the exact length of the year, we shall refrain from giving a decisive opinion on this subject. For more on the reduction of ratios, see Lagrange's Additions to Euler's Elements of Algebra.

RATIOS, Prime and Ultimate, is a species of computation, which we owe to the fertile genius of Newton. The ancients, in order to extend the geometry of right lines to curvilinear figures, had recourse to the method of exhaus-tions, in which they made use of what is called the reduction ad absurdum method, which, though logical, is extremely tedious, and to avoid which, Cavalieri proposed his method of indivisibles, published in 1635 under the title of "Geometria Indivisibilibus," in which he was followed by Dr. Wallis and others of the 17th and 18th centuries. In this method every line was supposed to consist of a number of other lines indefinitely small; every curve was considered as a polygon of an indefinite number of sides, each side being indefinitely small; a solid was supposed to consist of an infinite number of plane sections, or of indefinitely thin laminae, and so on; hypotheses which in many instances led to errors, which indeed it was very difficult to avoid.

To obviate the tediousness of the ancients, and to the inaccuracy of the moderns, Newton introduced his method of prime and ultimate ratios, the foundation of which is contained in the first lemma of the first book of his "Principia." Many difficulties have been started, and much controvery concerning the proof of it; all of which would have been avoided, had either the author or his readers observed, that he is in reality laying down the definition of a term, viz. being ultimately equal, and not proving a proposition. Taking, therefore, this first lemma for a definition, it may be illustrated as follows.

Let there be two quantities, one fixed and the other varying; if related to each other, that, 1st, the varying quantity continually approaches to the fixed quantity; and, 2dly, that the varying quantity never reaches or passes beyond that which is fixed; 3dly, that the varying quantity approaches nearer to the fixed quantity than by any assigned difference. Then is such a fixed quantity called the limit of the varying quantity; or, in other words, the varying quantity may be said to be ultimately equal to the fixed quantity. These three conditions may be expressed more distinctly thus: 1. The difference between the varying quantity and the fixed quantity must continually decrease. 2. This difference must never become either nothing or negative. 3. This difference must become less, in respect of the fixed quantity, than by any assigned ratio; or the difference between the two quantities must become a less part of the fixed quantity than any fractional part that is assigned, however small the fraction expressing such part may be. Wherever these properties are found, the fixed quantity is called the limit of the varying quantity, or the varying quantity is said to be ultimately equal to the fixed quantity. The last expression, however, must not be understood in its strict literal sense, there being no ultimate flux, no particular magnitude, that is the ultimate magnitude of such a varying quantity. Under the word quantity in this definition, must be included not only numbers, lines, &c., but more especially ratios considered as a peculiar species of quantity; but as the consideration
RATIO.

The sum of an infinite number of terms in this series be considered as continually increased by the addition of a new term; thus, the sum of the two first is \(\frac{1}{3} \), of three terms is \(\frac{1}{3} + \frac{1}{9} = \frac{1}{2} \), and of four terms is \(\frac{1}{3} + \frac{1}{9} + \frac{1}{27} = \frac{1}{2} \), &c.

and let the sum of an indefinite number of terms in this series be considered as continually increa
and let the sum of an indefinite number of terms in this series be considered as continually increa

Here it is evident, that the terms in this last series, which express the successive differences, will be

And thus, the sums of the terms will be

Let each of these sums be subtracted from the limit \(\frac{a}{a-b} \) and we have the successive differences \(\left(\frac{b}{a-b} \cdot \frac{b}{a-b} \right), \left(\frac{b^2}{a-b} \cdot \frac{b^2}{a-b} \right), \left(\frac{b^3}{a-b} \cdot \frac{b^3}{a-b} \right), \) &c. or if \(n \) be any assigned number of terms, the difference between the sum of that number of terms and the limit \(\frac{a}{a-b} \) will be \(\frac{b}{a-b} \cdot b^{n-1} \). Whence we may observe, if the number of terms whose sum is required increases, this difference continually decreases, because \(b \), being a fraction less than unity, its powers continually decrease.

For \(\frac{a}{a-b} = b \cdot \frac{b}{b} = a^2 \cdot b^2 \), or as \(a^2 \) to \(1 \) ; or as \(\left(\frac{a}{b}\right)^2 \) to \(1 \); and since \(b \) is greater than \(a \), and \(n \) indefinitely, the former term of the ratio may become greater than any assigned quantity, and therefore the ratio itself less than any ratio assigned.

The quantity \(\frac{a}{a-b} \), having, therefore, the required conditions, is the limit of the above series, or is equal to the sum of all the terms continued in infinitum.

What has been proved above may be shown more concisely by dividing \(a \) by \(a-b \), in the manner of division in algebra, for the quotients will be the very series proposed in the example: for instance,

\[
\frac{a-b}{a-b} = 1 + \frac{b}{a} + \frac{b^2}{a^2} + \frac{b^3}{a^3} + \&c.
\]

And
And it may be further confirmed by multiplying the proposed series by $a - b$, for the product will be $a$, all the terms except the first destroying each other.

We may also observe, that if every term of the foregoing series be multiplied by any number $c$, it will become $c + \frac{b \cdot c}{a} + \frac{b^2 \cdot c}{a^2} + \frac{b^3 \cdot c}{a^3} + \&c.$; a series having the same ratio, but whose first term is $c$; and it is therefore evident, that, in this case, we may find the sum of all the terms, we must multiply the former limit by $c$, whence it will become $\frac{a \cdot c}{a - b}$.

Before we begin to consider ratios, it may not be amiss to caution the reader against confounding the terms of a ratio with the ratio itself: the terms of a ratio may vary in some cases through all degrees of magnitude, and yet the ratio remain constant or invariable. In other instances, varying the terms in infinitium, likewise varies the ratio in infinitium: while in others, though varying the terms may also vary the ratio, yet the last ratio can never exceed certain limits.

Let $x$ be any varying quantity; make $4 \cdot x^2 + 3 \cdot x = A$, and $2 \cdot x^3 + x = B$; then will $A$ and $B$ also be varying quantities, as depending upon $x$; when $x$ vanishes, $A$ and $B$ will both vanish; when $x$ is infinite, they will be both infinite. I say then the ratio of $A$ to $B$, while $x$ decreases in infinitium, approximates to the ratio of $3$ to $1$.

For, first, $A$ is to $B$, as $4 \cdot x^2 + 3 \cdot x$ is to $2 \cdot x^3 + x$, or as $4 \cdot x + 3$ to $2 \cdot x^2 + 1$; where it is obvious, that as $x$ decreases, the quantities $4 \cdot x$ and $2 \cdot x^2$ also decrease, and consequently the ratio of $4 \cdot x + 3$ to $2 \cdot x^2 + 1$, or of $A$ to $B$, approaches to that of $3$ to $1$. Secondly, the ratio of $A$ to $B$ cannot exceed $3$ to $1$. For $6 \cdot x^2 + 3 \cdot x$ is to $2 \cdot x^3 + x$, as $3$ to $1$; but $4 \cdot x^2 + 3 \cdot x$ is a less quantity than $6 \cdot x^2 + 3 \cdot x$, therefore $4 \cdot x^2 + 3 \cdot x$ is to $2 \cdot x^3 + x$, or $A$ is to $B$ in a less ratio than $6 \cdot x^2 + 3 \cdot x$ to $2 \cdot x^3 + x$; that is, less than the ratio of $3$ to $1$. Lastly, the ratio of $A$ to $B$ will approach nearer to the ratio of $3$ to $1$, than any allowed difference. For in the terms of this ratio, $4 \cdot x^2 + 3 \cdot x$ to $2 \cdot x^3 + x$, by diminishing $x$, may become less than any allowed quantity, while the other parts, $3$ and $1$, remain the same; therefore the ratio of $A$ to $B$ will approach nearer to the ratio of $3$ to $1$, than by any allowed difference.

In like manner the ratio of $A$ to $B$, while $x$ increases in infinitium, approximates to the ratio of $2$ to $1$, as its limit.

For since $A$ is to $B$ as $4 \cdot x^2 + 3 \cdot x$ to $2 \cdot x^3 + 1$, or as $4 \cdot x + \frac{3}{x}$ to $2 + \frac{1}{x}$, it is obvious, that as $x$ increases, the quantities $\frac{3}{x}$ and $\frac{1}{x}$ decrease, and consequently the ratio of $4 \cdot x + \frac{3}{x}$ to $2 + \frac{1}{x}$, or of $A$ to $B$, approaches to the ratio of $4$ to $2$, or of $2$ to $1$. For $4 \cdot x^2 + 2 \cdot x$ is to $2 \cdot x^3 + x$, as $2$ is to $1$; but $4 \cdot x + 3 \cdot x$ is a greater quantity than $4 \cdot x^2 + 2 \cdot x$, therefore $4 \cdot x + 3 \cdot x$ is to $2 \cdot x^3 + x$, or $A$ is to $B$ always in a greater ratio than $2$ to $1$. Lastly, the ratio of $A$ to $B$ will approach nearer to that of $2$ to $1$, than by any allowed difference. For in the terms of this ratio, $4 + \frac{3}{x}$ and $2 + \frac{1}{x}$, the variable parts $\frac{3}{x}$ and $\frac{1}{x}$, by increasing $x$, may become less than any allowed fraction, while the parts $4$ and $2$ remain the same; therefore the ratio of $A$ to $B$ will approach nearer to the ratio of $4$ to $2$, or $2$ to $1$, than the allowed difference. Hence then we see that though diminishing $x$, and consequently diminishing the terms $A$ and $B$, we increase their ratio, and on the contrary increasing these terms, by increasing the quantity $x$, we decrease their ratio, yet there is a limit both to the increase and decrease of this ratio, although there be none to the terms themselves which compose it.

The ratio of $3$ to $1$, which limits the ratio of $A$ to $B$, when these terms decrease in infinitum, is called the ultimate ratio of the evanecent quantities $A$ and $B$. The ratio of $2$ to $1$, which is their other limit, is called the ultimate ratio of the quantities $A$ and $B$ increasing in infinitum.

Another example of a similar kind we have as follows. Let $x$ be a varying quantity, and $d$ a constant one, then will $x + d$ and $x$ be two varying quantities capable of all degrees of magnitude, I say that the ratio of $x + d$ to $x$, while $x$ increases, will continually decrease, but not beyond a certain limit, which is the limit of equality. On the contrary, if $x$ decreases, the ratio of $x + d$ to $x$ will continually decrease more and more ad infinitum, and never come to a limit. For $x + d$ is to $x$, as $1 + \frac{d}{x}$ to $1$; now as $x$ increases, the fraction $\frac{d}{x}$ decreases, and may become less than any allowed fraction; but the number $1$, which is the other part of the antecedent of this ratio, remains the same, as does likewise the consequent, therefore the ratio of $1 + \frac{d}{x}$ to $1$, continually approximates to a ratio of equality. Secondly, it can never reach that ratio, because $\frac{d}{x}$ has always some magnitude, and consequently $1 + \frac{d}{x}$ always greater than $1$. It therefore can never reach the ratio of equality, and much less can it pass it, so as to become a ratio minoris inaequalis, or a ratio in which the antecedent is less than the consequent. Lastly, the varying fraction $\frac{d}{x}$, as $x$ increases, will become less than any allowed fraction, while the other part of the antecedent, and likewise the consequent of this ratio, remain the same. Therefore the ratio of $1 + \frac{d}{x}$ to $1$, will approach nearer to the ratio of equality, than by any ratio that can be allowed, however small such ratio may be; therefore the ratio of equality is the limit of the ratio of $1 + \frac{d}{x}$ to $1$, and consequently the limit of the ratio of $x + d$ to $x$, which continually decreases, while the terms which compose this ratio continually increase in infinitum.

If $x$ decrease then $\frac{d}{x}$ will increase, and may become greater than any allowed number, while the other part of the antecedent, and likewise the consequent, remain invariable; therefore the ratio of $1 + \frac{d}{x}$ to $1$, and consequently the ratio of $x + d$ to $x$, as $x$ decreases, will become greater than any allowed ratio whatever, having no limit to its increase.
We may further observe, that though the terms of this ratio, viz. \( x + d \) to \( x \), never approximate nearer to each other, their constant difference being \( d \), yet the ratio of the terms approximates to the ratio of equality; that is, though the terms get no nearer in their difference, yet, if we may be allowed \( d \) the expression, they get nearer in their ratio. The difference of the terms, and the ratio of the terms, are ideas very distinct from each other, and in no wise to be so connected, but one may vary whilst the other is constant. Although the ratio of equality may strictly be called the limit of the varying ratio of the quantities \( x - d \) and \( x \), yet the terms of this ratio can never be literally said to be equal, nor ultimately equal, as that supposes an ultimate finite in which they are equal; nor equal when they vary into infinity, or, when they pass out of finity into infinity. There is no finite quantity next to infinity, no number, for instance, which is the next number to infinity. Nor is there any step from a finite into nothingness into finite existence; there is no fraction so small as to be the very nearest fraction to nothing; no fraction can be aligned so small, but another fraction may be aligned that is smaller. Neither can we say, in strictness, that two infinitely great numbers with a finite difference are equal, being a proposition obviously absurd and contradictory. There is no such thing in nature as an infinitely great number; and it is contradictory to say of two numbers, both that they have a difference, and that they are equal. Whoever considers that the idea of infinity is a general or abstract idea, that the idea of number is always particular, that infinity is a property of numbers, a property of extension, &c. itself, will readily perceive that these and such like expressions have no literal meaning. (See Locke, b. ii. ch. 16, and ch. 17.) As to the metaphorical use of them, to avoid circumscription, or the introduction of new terms, it may be allowed, when once the literal meaning has been explained, in this, as well as on various other occasions both in science and in common life.

When the difference between any two quantities decreases, so as to become a less fractional part of the one of them than any aligned fractional part whatever; or, when the difference between the terms of a ratio becomes less in respect of one of them (the greater for example) than any aligned ratio, this may be expressed by saying, that such difference vanishes in respect of that greater quantity. But if the difference between two terms vanish in respect to one of them, it will also vanish in respect of the other. It is true that at any aligned time, when the terms have a particular magnitude, the difference between the terms will always be a less fractional part of the greater term than it is of the less term; but as this difference continually decreases, it will become the same fractional part of the less term that was before of the greater, however small that fractional part of the greater term may be; therefore, if the difference vanish with regard to one of them, it will vanish also with regard to the other. We may, therefore, instead of the third condition of our definition, say, that "the difference must vanish in respect either of the fixed or of the varying quantity, since one of these implies the other."

The above is true as well for the case of two variables, as for one fixed and one variable, though both of such variables increase or decrease without limit. Thus, in the example above given, in which the terms were \( x + d \) and \( x \), and where \( x \) is continually increasing, the terms themselves both continually increase; for in this instance it is obvious, that if the difference vanish with respect to one of the terms, it will also vanish with respect to the other. Let \( x \) be to \( x \), at any aligned point of time, as \( n \) is to \( 1 \), and \( d \) at that instant of time will be the \( \frac{1}{n + 1} \)th part of the greater term, and the \( \frac{1}{n + 1} \)th part of the less term; now, though the contemporary value of these fractions can never be equal, yet in succession the value of the latter fraction will become whatever the former has been; therefore, if \( \frac{1}{n + 1} \) become less than any aligned fraction, so will \( \frac{1}{n} \) likewise; and thus, if the difference vanish with respect to one of the terms, \( x + d \), so will it also vanish with respect of the other, \( x \). And the same would be true if the terms were \( x \) and \( x - d \), all things else being as before.

Again, if \( x \) by decreasing vanish with respect to some fixed quantity \( n \), then will \( x \), multiplied by a given number \( n \), or \( n x \), vanish in respect of \( x \); or, which is the same, if \( x \) vanish in respect of \( a \), so likewise will the quantity \( n \) vanish; bearing to \( x \) the aligned ratio of \( n \). For though at any particular point of time \( x \) is a smaller fractional part of \( a \) than \( n \), \( x \) can be no aligned fractional part of \( a \) whatever; but by further diminishing \( x \), the quantity \( n \) may become the same fractional part of \( a \) that \( x \) was before. If, then, \( x \) may become equal to, or less than, any aligned fractional part of \( a \), so likewise may \( n \); that is, if \( x \) vanish in respect of \( a \), so likewise will \( n \).

For a like reason, if \( x \) vanish in respect of any quantity, it will likewise vanish in respect to that quantity multiplied or divided by any number; or it will vanish in respect of a quantity, bearing to any aligned ratio, as that of \( m \). Thus, if \( x \) vanish in respect of \( a \), it will also vanish in respect of \( 3 a \), or \( \frac{1}{2} a \), &c. Or, if any fraction vanish in respect to the diameter of a circle, it will likewise vanish in respect of the radius. For whatever part of the diameter the line \( x \) may be at any aligned point of time, let \( x \) further decrease, till it be half what it was at that aligned time, and it will now be the same part of the radius that it was before of the diameter; and the same with various other lines and quantities. We have shewn, in the preceding part of this article, that the ratio which two quantities bear to each other may have a limit, although the terms themselves may increase or decrease perpetually without limit. If the terms approximate towards each other; 2, if the less never pass the greater; and, lastly, if their difference vanish in respect of either term, then the limit of their varying ratio is that of equality; and this, whether the terms themselves are finite, as by increasing they both become greater than any aligned quantity, or, which is more common, such as by decreasing become less than any aligned quantity, or as it is called, infinitely small. Because the idea of the terms of a ratio is less abstract than that of the ratio itself, it is more usual to say that the terms themselves in this case are ultimately equal, though, strictly, it is the ratio only of the terms that comes to a limit, for the terms themselves are supposed to increase or decrease without limit, or as we commonly say, ad infinitum.

Prop.—In a circle whose centre is \( C \), (Plate XIII. Analytis, fig. 9,) radius \( C A \), diameter \( A a \), let \( A B \) be the chord, \( F \) the line, and \( A D \) the tangent of the arc \( A B \). If, that while the arc \( A B \) continually decreases without limit; \( F D \), the line continually approximates to the tangent; 2dly, the line never exceeds the tangent; 3dly, their difference will vanish in respect of either line or tangent.

First; \( B F : D A :: C F : C A \), but while the arc decreases, \( C F \) approaches to \( C A \); \( B F \) approaches to \( D A \).
RAT

D A. 2dly. C F can never exceed C A; therefore B F can never exceed D A. 3dly. The arc continually decreasing without limit, vanishes in respect of the diameter, which is fixed; therefore the chord A B, which is less than the arc, likewise vanishes in respect of the diameter A a. But A a = A B : A B = A F; therefore, if A B vanishes in respect of A a, A F will vanish in respect of A B; and much more will A F vanish in respect of A a; but if A F vanishes in respect of A a, it will also vanish in respect of 2 A a, or C A.

Now C A : C F :: A D : F B, and by division of proportion C A : A F :: A D : F B. Therefore, as A F vanishes in respect of C A, so does A D - F B (the difference of the fine and tangent) vanish in respect to A D the tangent, and consequently in respect of F B the fine. Whence we see, that while the arc continually decreases without limit, the fine approaches to the tangent; 2dly, the fine never exceeds the tangent; 3dly, although the fine and tangent both vanish in respect of the radius, yet their difference vanishes in respect of these quantities themselves. Therefore the ratio of equality is the limit of the varying ratio which the fine and tangent have to each other, while they both decrease perpetually without limit, or it is their ultimate ratio, or, as we may say, they are ultimately equal.

The fine is less than the chord; for in the right-angled triangle A F B, the side B F is less than the hypotenuse A B; the chord is less than the arc; this is self-evident, the chord being a straight line, and the arc a curve, both terminated by the same points A and B. The arc is less than the tangent; for from the point D draw another tangent to the circle in H; and the lines A B H, A D H, will be terminated by the same points A and H; and will have the concavities turned the same way; therefore the included arc A B H will be less than the sum of the two equal tangents D A and D H; consequently half that arc, or A B, will be less than half the sum of the tangents A D.

Cor. 1.—Hence the fine, chord, arc, and tangent, are all ultimately in a ratio of equality. This may appear because the chord and arc are included between the fine and tangent, but perhaps more plainly thus. Of these four quantities, viz. the fine, chord, arc, and tangent, the fine is the least, and the tangent the greatest; therefore, the difference between the fine and the tangent is greater than the difference between any other two of these four quantities. If, therefore, the greatest of all the differences vanishes in respect of the least of all these quantities, much more will the difference between any other two of these four quantities vanish in respect of the quantities themselves.

Cor. 2.—Join B a, and in the right-angled triangle B F a, the hypotenuse B a is greater than the side F a; therefore A a - B a is less than A a - F a, or than A F; but while the arc A B decreases continually without limit, A F vanishes in respect of A a; much more then does A a - B a, the difference A a and B a, vanish in respect of A a; therefore the ultimate ratio of A a to B a is that of equality; and the ultimate ratio of 2 A a, or B C to B a, is that of 2 to 1. See other applications of these principles in Ludlam’s ‘ Rudiments of Mathematics,’ from which the preceding article has been abstracted; Newton’s “ Principia,” lib. 1.; Smith’s “ Fluxions,” and Saunderson’s “ Algebra.”

RATIO, in our Late Writers, is used for a judgment given in a cause.

Hence, power ad rationem is to cite one to appear in judgment. Walsingham, 88.

RATIO Status, Ragion di stato. See REASON of State.

Vol. XXIX.
RATIONABILIBUS Divitis, is a writ that lies where two lords have signatures joining together, for him that finds his waite encroached upon, within the memory of man, against the encroacher, thereby to rectify the bounds of the signatures; in which respect, Fitzherbert says, it is of the nature of a writ of right.

RATIONABILIS Dos, a third part of such lands and tenements as the husband was seised of at the time of the espoufal, with which his wife was formerly endowed by the common law, if no specific dotation was made at the church porch. See Dower and Jointure.

RATIONAL, Reasonable. See Reason.

Rational Fable. See Fable.

Rational Fractions, in Arithmetic and Analysis, are those fractions into which no surd or radical quantity enters; as

\[ \frac{7}{19} \]

\[ \frac{5}{27} \]

The decomposition of rational fractions into simple fractions, that is, the decomposition of them into other fractions whose sum is equal to that proposed, is an important problem, as connected with the integral calculus, or inverte method of fluxions, which was first investigated by Leibnitz, but has since been much extended and simplified by the researches of Euler, La Grange, La Croix, and other eminent analysts.

The decomposition of numeral fractions into their partial fractions, is, perhaps, rather a subject of curiosity than utility, yet as connected with, and leading to, the decomposition of rational algebraic fractions, it may not be amiss to give here a sketch of the processes by which it is accomplished, previous to entering upon the latter subject.

On the decomposition of rational numeral fractions, into others having prime denominators.

It is to be observed, that this can only be effected in the case of a composite denominator, or rather, there will be no difficulty in any other case, as it will require only a separation of the numerator into any parts at pleasure, the sum of which is obviously equal to the fraction proposed; we shall therefore only consider those fractions having composite denominators, which are to be resolved into others having prime denominators; and even in this case there may be fractions that will not admit of decomposition, as will appear from what follows. This decomposition is effected, when possible, by means of the indeterminate analysis; viz. let \( \frac{m}{n} \) be the given fraction, and suppose, in the first instance, that its denominator consists of two prime factors, or \( n = ab \), it will then be to find \( \frac{m}{ab} = \frac{p}{a} + \frac{q}{b} \), or \( aq + bp = m \); \( p \) and \( q \) being the required numerators of the two partial fractions, and which values of \( p \) and \( q \) are easily found from the above equation \( aq + bp = m \), on the principles explained under the article Indeterminate Analysis, subject however to the same limitation there mentioned; viz. the above equation is always possible, provided \( m > ab - a - b \), but in other cases it may or may not admit of solution.

If the given fraction be \( \frac{m}{ab} \), then we may first resolve it into two fractions, and one of these into two others; thus, let \( \frac{m}{ab} = \frac{p}{a} + \frac{q}{b} \), then we have

\[ aq + bp = m \]

from which equation \( p \) and \( q \) may be found.

Again, let \( \frac{p}{a} = \frac{r}{a} + \frac{s}{b} \), which gives \( as + rb = p \),

whence \( r \) and \( s \) may be determined, and we shall thus obtain

\[ \frac{m}{a b} = \frac{r}{a} + \frac{s}{b} + \frac{q}{c} \]

as required. In all these cases it is obvious, that the fraction may be decomposed into partial fractions, in as many different ways as the indeterminate equation on which it depends admits of different answers.

Example.—Find two fractions, having prime denominators, whose sum shall be equal to \( \frac{19}{35} \) and \( \frac{7}{5} \).

Let the required fractions be \( \frac{p}{7} + \frac{q}{5} \), then \( \frac{p + 7q}{35} = \frac{19}{35} \); therefore \( \frac{p + 7q}{35} = \frac{19}{35} \), whence \( p = \frac{19}{35} \), and \( q \), for \( \frac{7}{5} \) (see Indeterminate Analysis); and consequently the required partial fractions are \( \frac{1}{7} \) and \( \frac{2}{5} \).

Example 2.—Find three fractions, whose sum is equal to \( \frac{401}{315} \).

The three factors of \( 315 \) are \( 5, 7, 9 \), which are of necessity the denominators of the required fractions. Suppose then first, that \( \frac{401}{315} = \frac{p}{35} + \frac{q}{9} \), whence we have \( 9p + 35q = 401 \), which gives \( p = 29 \), and \( q = 4 \); therefore \( \frac{401}{315} = \frac{29}{35} + \frac{4}{9} \). Again, let \( \frac{29}{35} = \frac{r}{7} + \frac{s}{5} \), or \( 5r + 7s = 29 \); this gives \( r = 3 \) and \( s = 2 \), so that \( \frac{29}{35} = \frac{3}{7} + \frac{2}{5} \), and consequently \( \frac{401}{315} = \frac{2}{7} + \frac{3}{5} + \frac{4}{9} \), as required. And in the same manner the decomposition may be obtained in any other case, which falls within the limits above stated.

On the decomposition of rational algebraic fractions, and its application to the integral calculus.

Let \( \frac{N}{D} = \frac{a + bx + cx^2 + dx^3 + \text{etc.}}{d' + d''x + d'''x^2 + \text{etc.}} \)

be any rational fraction, whose decomposition into simple fractions is required, and whose numerator is at least one degree lower than its denominator, to which form it may always be reduced by division, if it should present itself under a different form.

The denominator of this fraction, from the known theory of equations, may be supposed to be made up of as many simple factors as is equal to the highest power of \( x \) contained in it, and which factors may be found by determining the roots of the equation formed by putting the whole denominator equal to zero. Let therefore \( d' + d''x + d'''x^2 + \text{etc.} = 0 \), and suppose the roots of this equation to be \( r, r', r'' \), etc., and we shall have \( a + bx + cx^2 + dx^3 + \text{etc.} = (x - r)(x - r')(x - r'') \), etc.

And therefore our proposed fraction \( \frac{N}{D} \) may now be put under the form

\[ \frac{N}{D} = \frac{a + bx + cx^2 + dx^3 + \text{etc.}}{(x - r)(x - r')(x - r'')} \]

and these factors are now to form the denominators of the
RATIONAL FRACTIONS.

the simple fractions sought. Let A, A', A", &c. represent their numerators, so that

\[ \frac{N}{D} = \frac{A}{x - r} + \frac{A'}{x - r'} + \frac{A''}{x - r''} + \text{&c.} \]

Reduce now these several simple fractions to a common denominator by the usual rule, and add their several numerators together; then comparing the co-efficients of the like powers of \( x \) in the numerator of this new fraction, with those in the numerator proposed, we shall obtain sufficient equations for determining the proper values of \( A, A', A'', \text{&c.} \) and the decomposition will be effected as proposed. This will be better understood from a partial example.

Let us therefore assume the fraction \( \frac{6x^3 - 4x - 6}{x^3 - 6x^2 + 11x - 6} \), which it is required to resolve into its simple fractions.

Here the roots of the denominator, by making it equal to zero, are 1, 2, and 3; whence the proposed equation may be put under the form

\[ \frac{x^3 - 4x - 6}{x^3 - 6x^2 + 11x - 6} = \frac{A}{x - 1} + \frac{A'}{x - 2} + \frac{A''}{x - 3} \]

Make now this fraction \( \frac{6x^3 - 4x - 6}{x^3 - 6x^2 + 11x - 6} = \frac{A(x - 2)(x + 3) + A'(x - 1)(x + 3) + A''(x - 1)(x - 2)}{x^3 - 6x^2 + 11x - 6} \)

\[ = \frac{(A + A' + A'')(x^3 + (A + 2A' - 3A'')x - (6A + 3A' - 2A''))}{x^3 - 6x^2 + 11x - 6} \]

whence

\[ A + A' + A'' = 6 \]

\[ 6A + 3A' - 2A'' = 6 \]

from which we readily draw \( A = 1, A' = 2, A'' = 3 \); so that the required fractions are

\[ \frac{1}{x - 1} + \frac{2}{x - 2} + \frac{3}{x - 3} \]

If therefore the fluent of \( \frac{x}{x^3 - 6x^2 + 11x - 6} \) were required, we might immediately reduce the problem to finding the fluents of \( \frac{x}{x - 1} \), \( \frac{2x}{x - 2} \), \( \frac{3x}{x - 3} \), which are known, being hyp. log. \( (x - 1) + 2 \text{ hyp. log.} (x - 2) + 3 \text{ hyp. log.} (x - 3) = \text{hyp. log.} [(x - 1)(x - 2)(x - 3)] \]

The same method may be employed for all rational fractions, whose denominators are reducible to unequal simple factors, but as this cannot be generally effected when the highest power of the variable quantity exceeds the fourth degree, we are necessarily limited in our application of the rule, in consequence of the imperfection which still attends the general solution of equations. In the case, however, of equal factors in the denominator, a different process is required, which we will explain, after illustrating the above rule by two or three examples.

Required the fluent of \( \frac{(1 + x)x}{x^3 - x^5} \) by resolving it into its simple fractions.

Here the factors of the denominator being \( x \) and \( 1 - x \), we make

\[ \frac{(1 + x)x}{x^3 - x^5} \]

\[ = \frac{A}{x} \frac{x}{x^3 - x^5} + \frac{A'}{1 - x} \frac{x}{x^3 - x^5} \]

whence \( A = 1 \), and \( A' = 1 \), or \( A' = 2 \), therefore

\[ \text{fluent} \left( \frac{1 + x}{x^3 - x^5} \right) + \text{fluent} \left( \frac{x}{x^3 - x^5} \right) = \text{fluent} \left( \frac{2x}{x^3 - x^5} \right) \]

which are known.

Required the fluent of \( \frac{(x - 1)x}{x^3 - x^5} \), or of \( \frac{2(n - x)}{x^3 - x^5} \),

Here, by making \( x^3 - 2x^2 + \frac{1}{2}x^3 = 0 \), we have \( x = 1 \pm \frac{1}{2}\sqrt{2} \); make, therefore,

\[ \frac{(\frac{1}{2}x - \frac{1}{2})x}{x^3 - \frac{1}{2}x^5} = \frac{A}{x - 1} \frac{\frac{1}{2}x}{x^3 - \frac{1}{2}x^5} + \frac{A'}{x - \frac{1}{2}\sqrt{2}} \frac{\frac{1}{2}x}{x^3 - \frac{1}{2}x^5} \]

\[ = \frac{A}{x - 1} \frac{\frac{1}{2}x}{x^3 - \frac{1}{2}x^5} + \frac{A'}{x - \frac{1}{2}\sqrt{2}} \frac{\frac{1}{2}x}{x^3 - \frac{1}{2}x^5} \]

Here we have \( A + A' = -\frac{1}{2}(1 - \frac{1}{2}\sqrt{2}) \), \( A + \frac{1}{2}\sqrt{2} \), therefore fluent of \( \frac{(x - 1)x}{x^3 - x^5} = \text{fluent} \left( \frac{-\frac{1}{2}x^3}{x^3 - \frac{1}{2}x^5} \right) + \frac{A}{x - 1} \frac{\frac{1}{2}x}{x^3 - \frac{1}{2}x^5} \]

\[ = \frac{A}{x - 1} \frac{\frac{1}{2}x}{x^3 - \frac{1}{2}x^5} \]

We have hitherto considered the factors of the denominators of the proposed fractions to be all unequal; when any number of them are equal, a little difference in the operation is then required; for it is obvious that if two of our fractions were of the same form, for example \( \frac{A}{x - r} + \frac{A'}{x - r} \), these two would form, in fact, but one fraction \( \frac{A + A'}{x - r} \), which leads us to no useful result.

In case of equal factors, therefore, we must proceed as follows: let the proposed fraction be

\[ A + Bx + Cx^2 + Dx^3 + \ldots q(x - p)^{m - 1} \]

Assume it equal to

\[ \frac{B}{x - r} + \frac{B'}{(x - r)^{-1}} + \frac{B''}{(x - r)^{n - 1}} + \ldots \frac{B^{n - 1}}{x - p} \]

Where the upper line represents the fractions due to the \( m \) equal factors, and the lower those due to the \( n \) unequal factors.

Let now these fractions be reduced to a common denominator, and the co-efficients equated as before, which will give us the required values of the several numerators sought.

Example.—It is required to convert \( \frac{1 - 5x}{(1 + x)(1 + x)} \) into its equivalent simple fractions.

Assume

\[ \frac{1 - 5x}{(1 + x)^2(1 + x)} = \frac{B}{(1 + x)^2} + \frac{B'}{(1 + x)^3} + \frac{A}{1 - x} \]

\[ = \frac{B}{(1 + x)^2} + \frac{B'}{(1 + x)^3} + \frac{A}{1 - x} \]

\[ = \frac{B}{(1 + x)^2} + \frac{B'}{(1 + x)^3} + \frac{A}{1 - x} \]

whence

\[ \text{examples} = \frac{B}{(1 + x)^2} + \frac{B'}{(1 + x)^3} + \frac{A}{1 - x} \]

whence
RATIONAL FRACTIONS.

whence

\[ B + B' + A = 1 \]
\[ 2A - B = -5 \]
\[ A - B' = 0 \]

therefore

\[ B = 3, \quad B' = -1, \quad \text{and} \quad A = -1, \]

consequently

\[ \frac{1 - 5x}{(1 + x)^2 (1 - x)} = \frac{3}{1 + x} - \frac{1}{1 - x} - \frac{1}{1 - x} \]

We have in both the preceding cases extended the calculation to a greater length than it is necessary to observe in practical cases, in order that the reader might see distinctly the principles on which the decomposition depends. We shall now furnish him with an easier practical method, which we have extracted from Bonnycastle's Algebra, vol. i.

1. When the factors of the denominator of the given fraction are all unequal, or of the form

\[ \frac{N}{D} = \frac{A}{x-r}, \quad \frac{A'}{x-r'}, \quad \frac{A''}{x-r''}, \quad \frac{A'''}{x-r'''} + \&c. \]

take that which constitutes the denominator of the simple fraction which it is to be found, and let S denote the product of all the remaining fractions; then if the root or value of x, in that factor, be substituted for x in the formula \( \frac{N}{S} \), it will give the numerator of the fraction required.

2. If some of the factors are equal and others unequal, or of the form

\[ \frac{N}{D} = \frac{A}{x-r}, \quad \frac{A'}{x-r'}, \quad \frac{B}{x-r} + \frac{B'}{x-r'}, \quad \frac{B''}{x-r''}, \quad \frac{B'''}{x-r'''} + \&c. \]

let S denote the product of all the factors in the denominator, except one, as before; then find the simple fractions due to the unequal fractions as above, and for those of the equal factors proceed as follows:

1. \[ B = \frac{N}{S}, \quad \text{taking} \quad x \quad \text{in} \quad N, \quad \text{and} \quad S = p. \]

Let \( Q = \frac{N - B S}{x - p} \), then

2. \[ B' = \frac{Q}{S}, \quad \text{taking} \quad x \quad \text{in} \quad Q, \quad \text{and} \quad S = p. \]

Let \( Q' = \frac{Q - B' S}{x - p} \), then

3. \[ B'' = \frac{Q'}{S}, \quad \text{taking} \quad x \quad \text{in} \quad Q', \quad \text{and} \quad S = p. \]

Let \( Q'' = \frac{Q' - B'' S}{x - p} \), then

4. \[ B''' = \frac{Q''}{S}, \quad \text{taking} \quad x \quad \text{in} \quad Q'', \quad \text{and} \quad S = p. \]

&c. &c.

Which operation being performed, the sum of the fractions thus obtained, together with the former, will give all the simple fractions into which the given fraction is resolvable.

Example 1.—It is required to convert the rational fraction \( \frac{1 + x^2}{x - x^3} \) into its equivalent simple fractions.

Here \( \frac{1 + x^2}{x - x^3} = \frac{A}{x + x^2} + \frac{A'}{1 - x} + \frac{A''}{1 + x} \); whence, by the preceding rule,

\[ A = \frac{N}{S} = \frac{1 + x^2}{x - x^3} = 1; \quad \text{being} \quad a = x \]

\[ A' = \frac{N}{S} = \frac{1 + x^2}{x + x^3} = 1; \quad \text{being} \quad 1 = x \]

\[ A'' = \frac{N}{S} = \frac{1 + x^2}{x - x^3} = -1; \quad \text{being} \quad 1 = -x. \]

The required fractions are therefore

\[ \frac{1}{x} + \frac{1}{1 - x} = \frac{1}{x - x^3} \]

Example 2.—It is required to convert the rational fraction

\[ \frac{1}{x + x^2 + (1 + x)} \]

into its equivalent simple fractions. Here

\[ \frac{N}{D} = \frac{A}{x + x^2} + \frac{B}{x + x^3} + \frac{C}{(1 + x)^2} + \frac{C'}{x + x^2} \]

whence for \( x + x^3 \), the first factor, we have

\[ A = \frac{N}{S} = \frac{1}{x^3 - 2x^2 + x^2} = \frac{1}{x - x^3}, \quad \text{being} \quad x = 1. \]

\[ B = \frac{N}{S} = \frac{1}{x^3 - x^2 + x} = 1, \quad \text{being} \quad x = 0. \]

Let now \( Q = \frac{N - B S}{x + p} \)

\[ \frac{Q}{S} = \frac{1 + x - x^2}{x + x^2} = 1, \quad \text{being} \quad x = 0. \]

Let \( Q' = \frac{Q - B' S}{x - p} \)

\[ \frac{Q'}{S} = \frac{1}{x^2 - x - x^2 + x^3} = 1, \quad \text{being} \quad x = 0. \]

Again, for \( (1 + x)^2 \)

\[ C = \frac{N}{S} = \frac{1}{x^3 + x + x^2} = \frac{1}{x + x^3} \]

Let now \( R = \frac{N - C S}{x - p} \)

\[ \frac{R}{S} = \frac{1}{x^3 + x + x^2} = \frac{1}{x + x^3} \]

Therefore

\[ \frac{1}{x + x^2 + (1 + x)} = \frac{1}{x^3 + x^2 + x^2} = \frac{1}{x + x^3} = \frac{1}{x + x^3} + \frac{2}{x + x^3} + \frac{1}{x + x^3} + \frac{1}{x + x^3} \]

It is obvious, as we have before stated, that this decomposition of rational fractions must necessarily be affected as to its general application, by the imperfection of the theory of equations, which will not admit of a practical resolution of the denominator into its simple factors in all cases. It will also further appear, that, in case of any of the roots being imaginary, the same will necessarily enter into the numerators of the simple fractions. But this difficulty may be avoided: for since the imaginary roots of equations always enter in pairs, and the product of such pairs of roots being always real, being of the form \( x + 2 = x + a^2 + b^2 \), we may, instead of resolving the fractions into the simple fractions \( \frac{A}{x - r}, \frac{A'}{x - r'}, \frac{A''}{x - r''} \), &c. resolve it into as many of these fractions as it has rational simple factors, and into as many fractions of the form \( B x + C \) pairs of imaginary factors, and then proceed as before. We
We cannot extend our remarks to a greater length in this article; we must, therefore, refer the reader who wishes to see these principles more completely developed, to Euler's Analysis Infinitorum, vol. i. ch. 2 and 11; to La Croix's Algebra, and his Calcul Differentiel et Calcul Integral. See also Bonnycastle's Algebra, and Simpson's Fluxions.

RATIONAL or true horizon, is that whole plane is conceived to pass through the centre of the earth; and which therefore divides the globe into two equal portions, or hemispheres. See Horizon.

It is called the rational horizon, because only conceived by the understanding; and in opposition to the sensible or apparent horizon, which is visible to the eye.

RATIONAL integer, or whole number, is that of which unity is an aliquot part. See Number, and Aliquot part.

RATIONAL mixed number is that consisting of an integer, and a fraction; or of unity, and a broken number. Commensurable quantities are defined by being one to another as one rational number to another.

For unity is an aliquot part of a rational number; and a fraction has some aliquot part common with unity; in things, therefore, that are as a rational to a rational number, either the one is an aliquot part of the other, or there is some common aliquot part of both; therefore they are commensurable.

Hence, if a rational number be divided by a rational, the quotient is always a rational.

RATIONAL Physicians, in ancient medical history, the physicians of the dogmatic sect, who, in opposition to the empiric sect; the former appealing to certain theoretical principles in the application of remedies, while the latter relied entirely upon experience, and disclaimed all knowledge of first principles. The tenets of both these sects have been handed down to us by a classic author, Celsus, and have been given at length under a former article. See Empiric.

RATIONAL Quantity, or number, a quantity or number commensurable to unity.

Supposing any quantity to be 1, there are infinite other quantities, some of which are commensurable to it, either simply, or in power: these Euclid calls rational quantities. The rest, that are incommensurable to 1, he calls irrational quantities, or irrads.

RATIONAL Ratio. See Ratio.

RATIONAL Soul. See Soul.

RATIONALE, a solution or account of the principles of some opinion, action, hypothesis, phenomenon, or the like. Hence, RATIONALE is also the title of several books. The most considerable is the "Rationale of Divine Offices," by Guil. Durandus, a celebrated school-divine, bishop of Mende, finished in 1286, as he himself tells us. See Printing.

RATIONALE also denotes an ancient facerdotal vestment, worn by the high-priest under the old law; and called by the Hebrews, בּושָם, boshen; by the Greeks, ὑπερήφανος; by the Latin, rationale and pectorale; and by the English translators, breast-plate.

The rationale was a piece of embroidered stuff worn on the breast, about a span square. Du-Cange describes it as a double square of four colours, interwoven with gold, and set with twelve precious stones in four rows, on which were engraved the names of the twelve tribes, and fastened to the shoulder by two chains and two hooks of gold. The form of the rationale was preferred by God himself, Exod. xxviii. 15-29.

A rationale appears also to have been annually worn by the bishops under the new law. But authors are in doubt about its form; some will have it resemble that of the Jews; others take it to be only the pallium.

RATIONALIS, an officer mentioned in several ancient inscriptions.

Lampridius, in the life of Alex. Severus, uses rationalis as synonymous with procurator.

The rationales were interdicts or overseers under the emperors; and though Lampridius pretends they were first established by Severus, it is evident there were some under Augustus.

RATIONARIUM, among the Romans, a book which contained the accounts of the empire. It was otherwise called breviarium. See Breviary.

RATIONIS Ens. See Ens.

RATIONIS Difpinatio. See Distinction.

RATIONIS Os, in Anatomy, the bone of the forehead, otherwise called os frontis.

RATIBON, or REGENSBERG, in Geography, an imperial city of Germany, in the circle of Bavaria, and capital of a bishopric of the same name, situated at the confluence of the Regen and of the Danube. The town is large, populous, and fortified; and was anciently the capital of Bavaria, and the residence of its dukes. The emperor Frederic I. annexed it to the empire. This town is a staple, but neither its manufactures nor trade is very considerable; corn, wood, and provisions, are sent by the Danube to Vienna.

The number of inhabitants is about 24,000; 62 miles N.E. of Augsburg. N. lat. 48° 35'. E. long. 15° 50'.

The bishopric of Ratibon comprehends about 1283 parishes; and was founded, as it has been supposed, by St. Boniface, in the year 756. The seat of the bishop is at Ratibon, where, however, he has no Jurisdiction.

RATISKA, a town of Imperitia; 35 miles N.E. of Cotatis.

RATKAI, George, in Biography, born in 1613, of a noble family, in Hungary, entered into holy orders, and was made canon of the church of Zagrab. He obtained the esteeem of the viceroy of Croatia, John Draskovitz, who engaged him to compose the history of that province, and gave him free access to its archives. He accordingly published, in 1652, a very learned work, entitled "Memoria Regum et Banorum regnorum Dalmatiae, Croatica, Slavonice, inchoata ab origine fusa ulque ad annum." Gen. Biog.

RATLINES, or, as the feamen call them, Rutlins, or Ratlings, are certain small lines which traverse the shores of a ship horizontally, at regular distances above the dead-eyes upwards, and forming a variety of ladders, whereby to climb to any of the main-heads, or deck from them. Hence the term seems to be derived from rath, an obsolete word, signifying a hill. In order to prevent the ratling from slipping down by the weight of the sailors, they are firmly attached by a knot, called a clove-bitch, to all the shores, except the foremost or aftmost; where one of the ends, being fitted with an eye-splice, is previously fastened with twine-thread or pack-thread. Falconer.

RATNO, in Geography, a town of Lithuania, in the patinate of Brzec; 50 miles S.E. of Brzce.

RATOATH, a poor village of the county of Meath, Ireland, which, before the union, had its representatives in parliament. It gave name to a barony, and is 12½ miles N.W. by N. from Dublin.

RATOLY, a town of Hindooftan, in the circuit of Gohud; 25 miles S.E. of Raat.

RATON, a small island in the river La Plata, near Monte Video.

RATSCHA,
RAT

RATSCHA, or Retzka, a fortrees of Sclavonia, on the N. side of the Sava, opposite to the mouth of the Drin; 35 miles S.W. of Peterwardein.

RATTSCHITZ, a town of Moravia, in the circle of Brunn; 10 miles N.E. of Brunn.

RATSWUR, a town of Hindooftan, in the cincar of Aurungabad; 65 miles E. of Aurungabad.

RATTITK, a town of Bengal; 14 miles S.S.E. of Curruckpore.

RATTAN. See Ruatan.

Rattan Canes. See Canes.

RATTLES DnR, in Geography, a town of Bavaria, in the bishopric of Bamberg; 9 miles N. of Bamberg.

RATTEN. See Ratan.

RATTEN, in Rural Economy, a provincial word, used to signify a rat.

RATTENBERG, in Geography, a town of the county of Tyrol, with a citadel on the inn; 16 miles E.N.E. of Infruphr.

RATTIK, a town of the duchy of Hofstein; 6 miles N.N.E. of Lubeck.

RATTLE, among the Ancients, a musical instrument called by the Romans crotalum.

Mr. Malcolm takes the tinnittum, crotalum, and sistrum, to have been only fo many different kinds of rattles.

The invention of the rattle is ascribed to the famous mathematician Archytas; whence Arhythmell calls it archytas, Archytas's rattle. Diogenes adds the occasion of the invention; viz. that Archytas, having children, he contrived this instrument to prevent their tumbling about things about the house. So that how much soever some instruments have changed their ufed, the rattle, we are fure, has preferved its original application.

RATTLE, or Rattel, in Commerce, a weight in Arabia; a rattle of coffee contains, at Beteflagi, 145½ vials, and a farcle, or taziel, of 10 maunds, or 20 rattles, contains 290 vials; a farcel weighs 22½ lb. 6 oz. 4 dr. avoirdupois, and a bahar of 40 farcelés = 815½ lb. avoirdupois; 10 farcelés in Beteflagi are equal to 7 in Mocha; 16 vials of dates, candles, and iron, are reckoned to a rattle; but of all other forts of goods 15 vials make a rattle. The rattle is used in the bazar, or market, only. At Jiddah, another sea-port of Arabia, in the Red fea, the bahar contains 10 frasiel, 100 maunds, or 500 rattles, and the rattle 15 vials. The bahar weighs 222½ lb. English troy, or 183 lb. avoirdupois; and the maund 29 oz. 4½ dr. avoirdupois. Kelly's Un. Cambir.

Rattle-Snake Root, Dr. Witt's, a species of Pretnarath; which fee.

Rattle-Snake Weed, a species of Eryngium; which fee.

Rattle-Snake Islands, in Geography, a cluster of small islands at the western extremity of lake Erie.

Rattle-Snake Mountains, mountains of New Hampshire; 48 miles N. of Concord.

RATTLING in horfes, a term applied to a disagreeable noise produced in them by the entrance of the air between the internal parts of the sheath and the prepuce of covering, principally taking place in trotting or going fast.

RATTONNEAU, in Geography, a small island at the entrance of the harbour of Marseilles, which has a fortrees erected in the 17th century by the duke of Guife.

RATTRAY HEAD, a cape of Scotland, on the N.E. coast of the county of Aberdeen; 7 miles N. of Peterhead. N. lat. 57° 12'. W. long. 1° 44'.

RATULAH, a town of Hindooftan, in Oude; 15 miles N.E. of Fyzabad.

RATWAH, a town of Hindooftan, in the cincar of Golud; 27 miles E. of Gwalior.

RATZEBUR, in Geography, a town of Hinder Pomerania; 14 miles S. of New Stettin. N. lat. 53° 30'. E. long. 16° 14'.

RATZEBURG, a town of Germany, which gives name to a principality, situated on an island in a large lake; the lake is 30 miles long, and 9 broad, and boats pafs by it to Lubeck with goods and paengers. It was burnt by the Danes in 1653, and fince that dipter the streets have been regularly laid out, and the houses are built after the Dutch manner. In the market-place is the regency-office, and here is held the chief court of judicie and the confiftory; the garrison is quartered in barracks; 20 miles S. of Lubeck. N. lat. 53° 45'. E. long. 10° 46'. The principality of the fame name is ifuated between Mecklenburg and Saxo-Lauenburg, and extends about 10 miles each way. The land is fertile, and produces a confiderable quantity of wheat, besides feeding a number of cattle. It was converted from a bishopric into a principality by the peace of Welfphalia. It belongs to Mecklenburg-Strelitz.

RATZENSTEIN, a town of the duchy of Stiria; 5 miles S. of Windfhef Gratz.

RATZKINSCHA, a town of Hungary; 10 miles N.N.W. of Clakathurn.

RAVA. See Rawa.

RAVALEMENT, Fr. equivalent, among organ-builders and harpsichord-makers, to compass in English. The complete fet of keys, or whole fystem of musical sounds, (said Roulfeau in 1768,) instead of confining itself to four octaves, like common keyed-instruments formerly, extends now to five octaves, adding a fifth below double C, and a fourth above C in alt., including five octaves between the lowest F and the highest. (This was the common compass of our harpsichords made by Tabel, Kirckman, and Shudi, long before 1768.) The word ravalement is confined to keyed-instruments; there are no others of so extensive a compass as five octaves. But in the year 1777, when Dr. Burney firft compofed and published duets "a quatre mains," or for two performers on one instrument, the ladies, at that time wearing hoops, which kept them at too great a distance from each other, had a harpsichord made by Merlin, expressly for duets, with fix octaves; extending from the octave below double C in the base, to the octave above C in alt. in the treble. And as duets a quatre mains have been compofed by all the great masters in Europe since that time, instruments with additional keys are now become general. At firft it was only in the treble that the compo f was extended, except in the instrument above-mentioned by Merlin; but at present notes are added in the base to complete the fix octaves; and, indeed, the additional notes in the base are better worth having for particular effects, than thoefe in the treble; which often, from the shortness of the strings and feeble vibration, more reftemb the tone of wood than wire; whereas the tone of thofe in the base of large piano fortes, by the bell makers, is fo rich and full, that
that each found below double F resembles that of an organ-pipe in flow notes, more than the transient tone of a string.

Roufleau very justly observes, that almost all instruments are limited in their compass below, except harps and instruments with keys. The violoncello can go no lower than double C, its 4th string; nor the violin below G. The flute and hautbois defend only to D and C. But the notes in alt. have been extended in the acute to sounds that are seldom in tune, and never pleasing. Like rapid notes of difficult execution, they surprize, and the performer's dexterity is applauded; but neither the harmony nor the melody of very high or rapid sounds can excite rupture like those of moderate quickness, when produced with feeling and expression, in the middle of the scale.

RAVALSHE, in Geography, a town of Sweden, in Went Gothland; 24 miles N.W. of Uddevalla.

RAVANA, in Hindu Mythology. See Ravana.

RAVANA, in Geography, a town of European Turkey, in Macedonia; 16 miles E.S.E. of Saloniki.

RAUAND, a town of Perouin, in the province of Kerman; 105 miles E. of Sigran.

RAVA-POU, in Botany, Rheede Hort. Malab. v. 4. 99. t. 48. a plant erroneously cited by Linnaeus for his very different Myrtanthus bieusi. See GUETTARDA Speciosa.

RAUCA AVIS, in Ornithology, the name of a bird described by Nieremberg, as common about the lakes and rivers of America, and of the kingfisher kind, but nearly as large as a duck, and black on the crown, and white on the breast and belly. Its neck is naturally very long in proportion to its body, yet it can occasionally contract and shorten it in a very wonderful manner. It is a native of Mexico, and is esteemed very good for the table. Mr. Ray has placed this among the birds, the accounts of which he is distressed at.

RAUCH, in Geography, a town of Germany, in the lordship of Schwarzenberg; 10 miles S.W. of Scheinfeld.

RAUCHENEGG, a town of Audria; 2 miles W. of Baden.

RAUCHT, a town of Ruffia, in the government of Viborg, near lake Ladoga; 44 miles S.E. of Viborg.

RAUDANAGUR, a town of Bengal; 30 miles E. of Ramgar.

RAUDEM, a town of Prussia, in the palatinate of Culm; 10 miles N.E. of Culm.—Alfo, a town of Silesia, in the principality of Ratibor; 12 miles N.E. of Ratibor.

RAUDNZ, a town of Bohemia, in the circle of Schlan; 12 miles N.N.E. of Schlan.—Alfo, a town of Bohemia, in the circle of Chrudim; 16 miles N.W. of Chrudim.

RAUDRI, a name of the Hindu goddes Paravat, confort of Siva, the destroying power. In this character he may be considered as his Sakti, or energy in his form of Rudra, or Efe. Rudri, and Rudrata, are other modes of writing this name of the goddes in her avenging character, in which she does not apparently differ much from her attributes, as Sakti of Mahakala; under which name, and the others occurring in this article, distinguished by italics, farther and sufficient information may be sought. See also TRISAKTI-DEVI, and TAMASI.

RAUDTEN, in Geography, a town of Silefia, in the principality of Wohlan; 18 miles N.W. of Wohlan. N. lat. 51° 30'. E. long. 16° 15'.

RAVEL, a sort of bread, called also black-bythief, as being of a middle finenes betwixt white and brown.

RAVELIN, in Fortification, was anciently a flat bastion, placed in the middle of a curtain.

RAVELIN is now a detached work, composed only of two faces, which make a salient angle, without and sometimes with flanks; and raised before the curtain on the counter-scarp of the place; serving to cover it and the joining flanks from the direct fire of an enemy.

A ravelin is a triangular work, resembling the point of a balloon, with the flanks cut off. (See Plate V. Fortification, fig. 4.) Its use before a curtain is, to cover the opposite flanks of the two next bastions. It is used also to cover a bridge or a gate, and is always placed without the moat.

What the engineers call a ravelin, the soldiers generally call a demi-lune, or half-moon. See Demi-lune.

There are also double ravelins, which serve to defend each other. They are said to be double when they are joined by a curtain.

Ravelins, or half-moons, are constructed by setting off 50 toises from the re-entering angle O of the counter-scarp (Plate VII. Fortification, fig. 4.) on the capital O L of the ravelin, or on the perpendicular produced, and from the point L drawing lines to the shoulders A, B; whole parts L M, L N, terminated by the counter-scarp, will be the faces M O, O N, the semi-gorges of the ravelin required. Others will have the faces of the ravelin to terminate on the bastions within three toises of the shoulders, in which case the ravelins cover the flanks better than the others. The ditch before the ravelin is 12 toises, and its counter-scarp parallel to the faces of the ravelins, and made in a circular arc before the salient angle. When the ravelins are made with flanks, the faces should terminate those of the bastions, at least 5 toises from the shoulders. These flanks are made by setting off 10 toises from the extremities of the faces, and from the points thus determined, the flanks are drawn parallel to the capital of the ravelin. When redoubts, or keeps, are formed in the ravelin, this is done by setting off 16 toises from the extremities of the faces, on the semi-gorges from N to h, and from M to a; and from the points b, a, the faces are drawn parallel to those of the ravelin; the ditch before this redoubt is 6 toises, and its counter-scarp parallel to the faces. This work should be covered in the faces by a wall, a foot or two thick, garnished with loopholes for the musketry to fire through; and it will serve to secure a retreat for the troops who defend the ravelin; they may thus prevent the enemy from making a lodgment in the outward part of the ravelin, or at least greatly obstruct their attempts for this purpose. Nor can they be drove from this place, until the enemy has erected a battery, and brought cannon on the ravelin to batter the redoubt. When the counter-guard (which fee) is placed before the ravelin, 40 toises are set off on the capital of the ravelin from its salient angle to the salient angle of the counter-guard, and 20 on the counter-scarp of the ditch. For the construction of crown-works before the ravelin, see Horn-work. Within the ravelin are constructed a rampart of about 16 or 20 yards, and a parapet of about 6 yards: ramps are also annexed in the slope of a rampart, and a barbet, when it is proper, is constructed in a salient angle. In wet ditches, where the troops pass from the town to the ravelin in boats, it is proper to make, in the gorge of the ravelin, a kind of harbour, where the boats may be covered from the fire of the enemy. In dry fosses, there should be ramps or stairs in the gorge of the ravelin, to preserve a free communication, if the bridges should be broken down by the enemy's flot. The celebrated general Coehorn, in the ravelins which he built at Bergen-op-Zoom, contrived a very good defence for the covered way before the faces of the bastions, by making retired flanks in the breasts of the ravelin, where
one or two cannon might be placed as secure from the enemy's fire as those behind the orillon of a balloon. See Military Construction.

RAVELLO, in Geography, a sea-port town of Naples, in Principato Citra, the see of a bishop, united to Scala; 11 miles W.S.W. of Salerno. N. lat. 40° 35'; E. long. 12° 10'.

RAVELWATER, a river of the county of Antrim, Ireland, rising in the mountains in the northern part, and flowing through Ravel Glen to the river Main.

RAVEN, Corvus, in Aversion. See Corvus.

RAVEN, Corvus corax of Linnaeus, in Ornithology, a large bird of the crow kind, well known throughout the world, as being found in all climates, and all regions. The colour of the whole bird is black, finely glossed with a rich blue, the belly excepted, which is dullcy. The ravens build in high trees, or upon the ruins of lofty buildings in the neighbourhood of great towns, being held in the same veneration as the vultures are in Egypt, and for the same reason; for devouing the carcasses and flesh that would otherwise prove a nuisance. They lay five or six eggs, of a pale greenish colour, marked with small brownish spots. There are many fabulous stories of the longevity of the raven; but birds are in general long lived, and the crow kind not less so than the raven. The raven is a very docile bird, and may be taught to speak, as well as to fetch and carry. In clear weather, ravens are remarked to fly in pairs at a great height, making a deep loud noise, different from the common croaking; and their feat is remarkably good. See Corvus corax.

The quills of a raven are used in tuning the lower notes of a harpichord, when the wires are fast at a considerable distance from the flets.

It is rare to find this creature white, yet it happens sometimes. Boyle mentions one. There was also one shewn to the Royal Society some years ago. Boyle's Works V. ii. p. 46.

RAVEN, Night, an English name for a heron, which flies in the night, and makes a very odd and hoarse noise. It has been applied by some to the bittern, or Ardea heliocris, but improperly, belonging of right to the smaller grey heron, called nightjar. See Heron.

RAVEN, Sea, or Carvorant. See Corvus Aquaticus.

RAVENA, in Hindu Mythology, is the name of a celebrated king of Lanka, or Ceylon. Such was his prowess, and the opposition which he exerted over his subjects, that it became necessary for Vishnu, the preserving power of the deity, to defend on earth for his destruction, and the relief of the suffering world. He accordingly became incarnate in the person of Rama; and the wars that ensued between the forces of the tyrant and the divine general, for the recovery of Sita, his ravished spouse, are the subject of the fine epic poem, the Ramayana, under which article of this work, and under Rama, and other themes referred to the poem, and the historical traditions connected with these points, are sufficiently described and discussed.

Although obscured by mythological fables, these persons and wars are admitted to have had historical existence; and some important points of chronology hinge upon them. We have, therefore, in this and other articles, noticed at some length the legends connected with these subjects.

In the Hindu theology, the origin of Ravana is thus related. Two ehirial wardens of Vishnu's palace carried the pride of office so far as to inful the seven Maharhini, (see Maharini, or Rish,) who had come to offer their adorations. The offended saints pronounced an imprecation on the inful warders, condemning them to be adhe-

yoni, or born below, thrice in mortal forms, before they could be readmitted into the divine presence. The imprecation of a Rishi, even if provoked by a god, is scarcely to be averted; and the offenders, in consequence, appeared in their first birth as Hiranyaksha, or golden-eyed, and Hiranyakusha, or clad in gold; secondly, as Ravana and Kumbhakarna; and lastly, as Kan Ка and Sihipala.

The history, if such it may be called, of Ravana, Rama, &c. is perpetually alleged in the Hindu writings; the Ramayana, containing an infinity of such legends, being one of the most popular works of the East. Ravana, or Ravan, has become a generic name for a tyrant. He is also called Dasaagriya, or the ten-necked; he being usually represented with that number of heads, and twenty hands, symbolical of patience and power. A couplet in the Ramayana may be thus translated. "Where Ravana is, the sun loses his force, the winds cease to blow, the fire ceases to burn; the rattle ocean, seeing him, flails its waves." Such are the hyperbolical relations of his potency, obtained by the usual process of self-inflicted auries. So ardent was he in this irresistible species of merit, that he offered to Siva nine of his ten heads successively; and thus exhausting the force of the condescending deity, pleased with such an important sacrifice, he obtained a promise, with some equivocal stipulations, of whatever he should desire. This fort of aiership is called Topas, under which word some account is offered of various modes of practising it. The gods and demi-gods, alarmed at Siva's promise, besought him to recall it. But such conduct is deemed unbecoming in deities, who, however, do not scruple to evade the performance of their promises by deceit or prevarication: and, on this occasion, Nareda was deputed to found Ravana as to what he would demand, which, as usual, was universal dominion. &c. Nareda artfully persuaded Ravana that Mahadeva (or Siva) was drunk, and had promised him what he could not perform: whereupon the vindictive giant tears up Kailasa, the paradise of Siva, which, being contrary to the stipulations, releashes Siva from his promise, and he contends to the destruction of Ravana, which is brought about by the avatars, or deacons, of Vihira in the person of Rama. From this story we are told to learn that all worldly affairs are the pre destined ordinances of providence; whose will, that any event should take place on earth, includes proficently all the routine and detail of its accomplishment; although we only see the links of a chain of causes leading naturally to its effect.

We will here add an extract from the Hindu Panteon, whence a considerable part of this article is taken, shewing how unceasingly the mythological machinery of that poetical people is introduced into their popular works. The names distinguished by capitals imply that articles are given under those words, in this work; and a reference may be made to them for any desired information.

"Respecting Ravana," says the author of the publication adverted to, "I will notice but one more tale, as related to me by a Brahman; who, unable fully to make me feel the poetical beauties, or comprehend the morality of the Ramayana, blushed while he developed its follies; which, in conformity with popular taste, or if taken separately, are apparently very numerous; although it must be confessed, they are so contrived as to be intimately connected with the main action of the poem. The following is an extract from the description; but I shall not here explain the causses that led to the predicament, or the consequences that ensued."

"Ravana, by his power and infernal arts, had subjugated all
all the gods and demi-gods, and forced them to perform menial offices about his person and household. Indra made garlands of flowers to adorn him withal. Agni, or Parvata, was his cook. Surya, regent of the sun, fulfilled light by day; and Soma, regent of the moon, by night. Varuna, the Hindo Neptune, purveyed water for the palace of Kuvera, the Plutus, furnished cloth. The whole nine planetary spheres, including Raishu and Ketu, sometimes arranged themselves into a ladder, by which, they served as steps, the tyrant ascended his throne. Brahma (for the great gods were there also, and I give this anecdote as I find it in my memoranda, without any improved arrangement) was a herald, proclaiming the giant's titles, the day of the week, month, &c., daily in the palace; a sort of speaking almanac. Mahadeva, in his character or incarnation of Kanadeh-Rao, performed the office of barber, and trimmed the giant's beards. Vishnu had the honourable occupation of instructing and drilling the dancing and finging girls, and selecting the fairest for the royal bed. Ganea, or Pollear, had the care of the cows, goats, and herds. Vayu swept the house. Yama washed the linen. And in this manner were all the gods employed in the menial offices of Ravena, who rebuked and flogged them in default of industry and attention. Nor were the female divinities exempted: for Parvati, in her form of Satwini, was head Aya, or nurse, to Ravena's children. Lakshmi and Saraswati were also among them, but it does not appear in what capacity. Earthly kings and queens were also forced into this degrading servitude, to the number of ninety-six royal families; as is said to be detailed in the Ramayana. But I have some doubt if such a relation be actually in this shape, in that poem: this we shall see, when its other books are translated and published. In my abstract of it, however, such a godly predicament seems effential to the main action; Rama being thereby impelled by every consideration of piety and duty to immediate and energetic measures, for the relief and liberation of the degraded divinities.

Ravana, as we have noticed, is surnamed Dala-griva, or the ten-headed. He is also called Vifravana, or Ion of Vifrava, the father likewise of Kuvera. The brothers are sometimes named Pala-fiya, or Pala-fiya. (See these articles.) Another of his names is equivalent to lord of Rakshashing, a race of malignant beings, common agents in the hands of superhuman tyrants for the annoyance of the virtuous portion of mankind, or thwarting the benificent views of the gods. Many specific varieties of these demons are enumerated in the first book of the Ramayana, as aiding Ravana in defence of himself and his kingdom of Lanka. In pictures illustrative of the Ramayana, which are very common throughout India, they are depicted especially ill-favoured, painted green, red, blue, &c. and engaged in fierce contels with Rama's human followers. Several leagues of these Rakshas, each of 14,000, were destroyed by Rama. See RAKSHA.

RAVENALA, in Botany, Adans. Fam. des Plantes, vol. 2. 67. See URANIA.

RAUENBACH, in Geography, a town of Germany, in the principality of Anspach; four miles S.S.W. of Anspach.

RAVENCLAS, a market-town and sea-port in the parish of Manchester, Allerdale ward, above Darwent, county of Cumberland, England, is situated on the Solway Firth, near the confluence of the rivers Esk, Mite, and Irri. Though possessing many advantages for trade, it is but a poor place, and chiefly supported by its oyster fishery, for which it is much celebrated. This town stands at the distance of 57 miles S.S.W. from Carlisle, and 287 N.W. by N. from London. The manor originally constituted part of the barony of Egremont, but was granted by Richard Lucy to the Penningtons, from whom the present owner, Lord Muncaffer, is lineally descended. The market day is Saturday, weekly; and there are two annual fairs, one of which is held on the eve, day, and morrow, of St. James, and is remarkable for the ceremonies attending its proclamation and continuance. On the first day, the earl of Egremont, or his proxy, attends, accompanied by the feigners of the borough of Egremont, with the insignia, called the Bow of Egremont; by the foresters, with their bows and arrows; and by all the tenants of the forest of Copeland, who hold their cattles by the special service of attending the earl, or his representative, during the fair. On the third day, at noon, the earls, officers, and tenants of the forest, depart, after proclamation; and lord Muncaffer, and his tenants, take formal re-possession of the place, and the day is concluded by horse-racing, and various rustic diversions.

Near Ravenflas, on the northern bank of the river Ekr, stands Muncaffer-house, the seat of lord Muncaffer; and call from it, on the opposite side of the river, are seen ruins of considerable magnitude, respecting which no historical documents are known to exist. They are now called the city of Bornfeir; and its foundation is ascribed, by tradition, to the Danes, who are said "to have gathered for its inhabitants the men of Drig, and the women of Beckermont," whence the popular saying, "let us go together like lads of Drig and ladies of Beckermont." These ruins extend about three hundred yards in length from east to west, and 100 in breadth, from north to south; and are enclosed, except at the east end, by a wall, nearly three feet in height. "There appears," says Hutchison, "to have been a long street, with several courts; the remains of the houses and buildings within the walls are not very numerous; but on the outsize they are innumerable, especially at the south side and west end. The circumference of the city, and suburbs, is nearly three computed miles; the figure is an oblong square. There is an ancient road through the city, leading from Ulpha to Ravenflas. About the year 1730, a considerable quantity of silver coin was discovered in the ruins of one of the houses, concealed in a cavity formed in a beam." A History of the County of Cumberland, &c. by William Hutchison, F.S.A., two vols. 4to. Beauties of England and Wales, vol. iii., 1802, by John Britton and Edward Wedlake Brayley.

RAVENNA, a very ancient city of Italy, in the department of the Amone, seated on the river Mentone, near the Adriatic. This city, as Strabo informs us, was built by the Thellians, on several islets, long before the war of Troy, and they were driven out by the Tufcans. In the time of this Greek writer, it was situated in the midst of a marsh, and attached to the continent, and in process of time the Po accumulated mud and sand, so that the land was raised and the sea removed to a greater distance. The Roman writer informs us, that it was made a Roman colony by Augustus; and Dion says, that a fleet of 250 vessels was flationed in this port by that prince, from which circumstance it was called "portus clarus," or the port of the fleet. He flationed, lays Suetonius, one fleet at Misenum, and another at Ravena, for guarding the upper and lower sea. Tiberius repaired its walls, and erected some new gates, which still bear an inscription to this purpose. Trajan also contributed towards embellishing this city. Honorius made it the place of his residence, both before and after Alaric had captured and burned Rome. When Odoacer made a conquest of Italy, he resided at Ravena, and fublained here a siege;
of three years, at the termination of which he was taken
and slain by Theodoric. Theodoric fixed the seat of his
empire in this place, and adorned it with magnificent churches
and palaces, and re-constructed the aqueduct of Trajan.
His daughter Amalaetha, and his grandson Athalaric, con-
tributed towards the improvement of this city. When
the Goths were driven from Italy by Naries, general of the
emperor Justinian, he was made governor of Ravenna; and
having continued in this station for 16 years, he was recalled
by Justin II., successor to Justinian; and in the year 567, he
was succeeded by Longinus, who took up his residence at
Ravenna, under the title of exarch. (See Exarch.) The
famous battle of Ravenna was fought near this town between
Gafton de Foix, duke of Nemmes, and nephew of Louis XII.
and the army of pope Julius II., Ferdinand, king of Spain,
and the Venetians, in which the former young general, being
only 24 years of age, having killed between 16 and 18,000
of the enemy, proved victorious, though he himself was
killed by too ardently following the pursuit. This happened
on Easter-day 1512. The French, enraged by the loss of
their brave general, took Ravenna by storm, and pillaged
the city with such severity that it has never recovered. On
the road to Forli, by the banks of the little river Rocce,
three miles from the city, a cross shews the spot where Gar-
ton de Foix was killed. Fresh water has always been to
scare at Ravenna, that it has excelled a pleasant epigram by
Martial. This city was late the seat of a vast hermitage,
with the title of an archbishopric. It has produced several
perious of eminence, as Faustinus, often mentioned by Mar-
tial; the sophost Alphaius, who lived under the reign of Alex-
er Severus; Caflidonus, chancellor to Theodoric, king of
the Goths in Italy; pope John XVII.; Peter Damiea,
cardinal of Ofa, and several others. Ravenna was also
the seat of many councils at successive periods. The three
best councils, in 1311, 1314, and 1317, were summoned for
the purpose of reforming the corrupt manners of the eccle-
siastics, which were, in those days, very debauched. It
is now a mean and inconsiderable town; the houses are old
and in a ruined state, and the number of inhabitants scarcely
amounts to 14 or 15,000. In the time of the Romans, it
was sat on a kind of bay formed by the Adriatic, and
its harbour was celebrated; but it is now three miles from
the sea. The mud thrown up by the tide having formed a
tract of land, which is cultivated, and on which the city it-
self has been enlarged towards the sea. The air is infal-
lubrious; but has been somewhat amened by conveying along
the sides of the city the rivers Mentone and Ronco, which
carry off the salted water from the marshy grounds. It
contains several churches, and 24 convents; 42 miles E.
of Bologna. N. lat. 44° 27'; E. long. 11° 5'.
RAVENPOINT, a headland of the county of Wex-
ford, Ireland, at the N. side of the entrance into Wexford
haven. N. lat. 52° 23'. W. long. 6° 18'.
RAVENSFARAS, in Botany, a barbarous appellation,
attributed by Sommert from the Magadafaric name of the plant,
Raven-fara, or Ravenfara, meaning, it seems, a good
leaf, and applying to the aromatic qualities, and economical
uses, of the leaves. Hence Juffieu was induced to contrive
the apt generic name Agathophyllum, from agathos, good or
profitable, and phylleum, a leaf; under which this genus ought
to have been described in its proper place, in our first volume.
But one of our predecessors has, by mistake, referred the
reader to Ravenfara, as a genuine Linnean name, attribu-
ting Agathophyllum to professor Martyn; see that
article. To correct this error, and supply the confquent
deficiency, we subjoin an account of the tree in question, un-
der its proper and received denomination.

Hull. t. 825. (Ravenfara; Sonnerat Ind. Occ. v. 2, 226.
Euodia; Gartn. t. 103. Lamarck Illitr. t. 404.)—
Clafs and order, Dodonaei Monogynia. Nat. Ord.
uncertain, perhaps akin to the Lauri, Jull.
Gen. Ch. Cot. Perianth inferior, very small, abrupt,
etire, permanent. Cor. Petals fix, ovate, incerfed into
the calyx, somewhat villous on the inside. Stam.
Filaments twelve, broadish, very short, alternately incerfed into
the base of the petals and the inside of the calyx; anthers
roundish. Pfl. Germin superior, very small; fìdle very
short; stigma downy. Peric. Drupa nearly globose, umbil-
icated. Seed. Nut the shape of the drupa, tipped with a
small abrupt point, divided internally half way, into fix
coriceous cells; kernel convex above, fix-lobed below, one
lobe being received into each cell.
Eff. Ch. Calyx abrupt, entire. Petals fix, incerfed into
the calyx. Drupa superior, nearly globose. Nut with fix
incomplete cells. Kernel solitary, with fix lobes.
Obli. Schreber, by a casual oversight, describes the fruit
as crowned with the calyx, though he justly terms the ger-
men superior.

1. A. aromaticum. Willd. n. 1. (Ravenfara aromatic&auml;
Sonnerat Ind. Or. v. 2, 226. t. 127. Euodia Ravenfara;
Gartn. v. 2, 101.)—Native of Madagascar. A large and
tufted, somewhat pyramidal tree, with a reddish aromatic
bark, and heavy, hard, inodorous, white wood, intermixed
with red fibres. Leaves alternate, filked, simple, obovate,
entire, generally obtuse; smooth on both sides; pale and
rather glaucous beneath; single-ribbed, of a firm or cori-
aceous texture. Flowers very minute, numerous, in axillary
panicles about the ends of the branches, shorter than the
leaves. Fruit an inch in diameter, solitary at the end of
each branch, so that, as Sonnerat remarks, one would think
the flowers had grown on a different tree; the panicles being
obliterated, probably, in consequence of one flower alone,
in each, bearing fruit. The tree produces fruit at the age
of five or six years, which is ten months in coming to per-
fecion. The inhabitants of Madagascar gather it at the
age of fix or seven months, as being, in that state of growth,
more fit for use as a spice. The kernel, when fresh, has
a fine aromatic odour, but its taste is bitter, and so highly
acid as to turn the throat very disagreeably. The leaves
are also very aromatic, and being made into a fort of gar-
lands, are left for a month in the open air to dry after
which they are plunged, for four or five minutes, into boil-
ing water, and then dried, either in the sun, or by a fire.
The flowers are treated in the same manner. The flowers
appear in January or February. The dried leaves, as well as the
fruits, of this tree, are said to partake of the colours of the
four most esteemed spices. They have not, however, come
into use as an article of commerce, though some of the
French, resident in Madagascar, have endeavoured to call
the attention of their countrymen to this object. Gartner
found the oduir of the fruit; though agreeable, too weak
to promise much utility.

RAVENSBURG, in Geography, a county of Germany,
lying between the bishoprics of Minden, Osnaburgh, and
Paderborn, the principality of Minden, and the counties of
Schaenen and Lippe. The soil is in some parts sandy,
but in others, especially towards the principality of Minden,
it produces corn, flax, and hemp; coal is found in some of
the mountains, and good stone for building. Its name is
derived from that of an ancient cattle, and it had formerly
its own counts. It latec belonged to the king of Prufia;
but by the peace of Tilsit was transferred to the kingdom
of Willphalia.
RAV

Weilphalia. The approaching congress (1814) may possibly fix its future destination.

RAVESNBURG, a town of Bavaria, which anciently belonged to the Guelphs, counts of Altorf; but it was an imperial town before the time of king Rodolphus, and continued such till the year 1802, when it was given, among other indemnities, to the elector of Bavaria. The Roman Catholics and Lutherans are united with regard to the temporal and spiritual concerns of the place, and the magistracy is shared betwixt them. They have one church in common; but the Lutherans are exclusively professed of another, and the Roman Catholics have also two parish-churches; 21 miles N.E. of Constance. N. lat. 47° 35'. E. long. 9° 38'.

RAVESBURG, a town of the Rhein palacemate, on the Elfas; 16 miles W. of Heilbronn.

RAVESBURNS, a small stream of England, which runs into the Thames between Greenwich and Deptford.

RAVESCROFT, THOMAS, in Biography, an active English musician and publisher, who flourished from the beginning of the 17th century to 1658. He was the editor and composer of the best collection of psalm tunes in four parts, which had till then appeared in England. He was a bachelor of music, and a professor not only well acquainted with the practice of the art, but seems to have bestowed much time in the perfecting of the best authors, and in meditation on the theory.

This book, published in small octavo, 1621 and 1631, contains a melody for every one of the hundred and fifty psalms, many of them by the editor himself, of which a considerable number is still in use; as Windsor, St. David's, Southwell, and Canterbury. There are others, likewise, which are sung by the German, Netherlandish, and French Protestants. To these the base, tenor, and counter-tenor parts have been composed by twenty-one English musicians: among whom we find the names of Tallis, Dowland, Morley, Bennett, Stubbs, Farneby, and John Milton, the father of our great poet. The tunes which are peculiar to the measure of the 100th psalm, the 113th, and 119th, were originally Lutheran, or perhaps of still higher antiquity. And though Ravencroft has affixed the name of Dr. John Dowland to the parts which have been set to the 100th psalm, yet, in the index, he has ranked the melody itself with the French tunes; perhaps from having seen it among the melodies that were set to the French version of Clement Marot and Theodore Beza's Psalms, by Goudimel and Claude le Jeune. Ravencroft, in imitation of these harmonists, always gives the principal melody, or as he calls it, the play-song, to the tenor. This part, indeed, he sometimes erroneously terms Fainbur. This is a corruption of faux-bourdon, and solfe bordons, which originally implied such simple harmony as arises from a series of thirds and sixths to the base. His publication is, in some measure, historical: for he tells us not only who composed the parts to old melodies, but who increased the common rock, by the addition of new tunes; as well as which of them were originally English, Welch, Scots, German, Dutch, Italian, French, and imitations of these.

No tunes of triple time occur in Claude le Jeune, and but five in Ravencroft: the principal of which are Cambridge, Martyrs, Mansehill, and the Shift. This last is still much used, and often played by clowns: it is called an imitation of a foreign tune, and has the name of Richard Allison prefixed to it. Muller's German edition of the psalm tunes at Frankfurt is exactly that of Claude le Jeune, in two parts only; except that he has transposed some of the melodies, and inverted easy leading and connective notes, to shift, not only the finger, but sometimes the tunes themselves; which, without them, would now be very bald and uncouth. Many of these old melodies are still sung to German hymns as well as psalms.

In 1614 Ravencroft published "A brief Discourse of the true, but neglected, Use of characterizing the Degrees by their Perfection, Imperfection, and Diminution in measurable Musick, against the common Practice and Custome of the Times," 4to.

Ravencroft had been educated in St. Paul's choir, under Mr. Edward Pierce, and was particularly conversant with old authors; he, therefore, wished to revive the use of those proportions in time, which, on account of their intricacy, had been long discontinued.

Ravencroft practiced these exploded doctrines ineffectually, though to his Discourse he added examples to illustrate his precepts, expressed in the harmony of four voices, concerning the pleasure of the five usual recreations of hunting, hawking, dancing, drinking, and enamouring. He was not always very successful in his attempts at imitative harmony; and melody was then so crude and uncouth throughout Europe, as to afford little facility in imitative strains.

Ravencroft was also the author of a collection of songs, entitled "Melecmata, Musicales Phanciales, fitting the Court, City, and Country Humours, in three, four, and five Voyces," published in the year 1611.

RAVESCROFT, JOHN, one of the waits of the Tower Hamlets, and in the band of the Goodman's-fields play-house, was a ripieno violin; yet, notwithstanding so humble a station, he was a performer of sufficient abilities to lead in any such band as that just mentioned; and could perform with great firmness a concerto of Corelli, or an ovation of Handel. He was in great request at balls and dancing parties; but excelled most others, not only in playing upon pipes with the true sailor's slang, but in composing them: and there are two of his compositions, that a tar, if he had any leg to stand on, would irretrievably be impelled to dance, the moment he heard them.

RAVENSPUR, or RAVENSBER, in Geography, was formerly a noted sea-port at the mouth of the Humber. It is celebrated by our historians for the descents of Henry IV. A.D. 1399, and of Edward IV. A.D. 1471, when these princes came to contend for the crown of England. It was shortly after, however, swallowed up by the ocean, together with many villages in its vicinity. The precise spot on which it flood is now unknown; but it is usually supposed to have been placed very near to Spurn Head, the Oxulum Promontorium of Ptolemy. For some additional account of the coast here, see PATRINGTON.

RAVENSTAIN, a town of Saxony, in the circle of Erzeburg; 8 miles, N.N.W. of Wolkenstein.—Alto, a town of Hinder Pomerania; 7 miles E.S.E. of Zachan.

RAVESTAIN, a town of Brabant, on the S. tide of the Meuse, the capital of a signatory, including 14 towns and villages; 15 miles N.E. of Bois le Duc.

RAV, a name, in Sanfedri, of Surya, the Hindoo regiment of the fun. It means the River, and has perhaps other meanings. See Surya.

RAVIERES, in Geography, a town of France, in the department of the Yonne; 27 miles E. of Auxerre.

RAUJESHER, a curacy of Bengal, bounded N. by Rajmal, E. by Bettoorish, S. by Mahmudli, Shahjule, and Kifhenagur, and W. by Birbosm and Hindoos; about 55 miles long, and 18 broad. The capital is Mouorbedbad; which see.

RAVILLE, a town of France, in the department of the Mofelle; 5 miles S. of Bouley.

3 Oz

RAVILLY,
RAVILLY, a small town of the county of Carlow, Ireland, in the barony of the same name. It is situated on the river Slaney, 3 miles S. from Baltinglas, and 32 miles S. by W. from Dublin.

RAVINA, a town of European Turkey, in Albania; 52 miles E. of Valona.

RAVINE, in Field Fortification, a deep hollow, usually formed by a great flood, or long continued running of water, frequently turned to good purposes in the field.

RAVIS, the fame with raucoo. See Hoardliness.

RAVISHMENT, is Luxus, denotes an unlawful seducing either a woman, or an heir in ward; for which there is a remedy by a writ of ravishment, or action of trelpeas en & armis, &c. he may have it de usque rapit et abducit, on account of the abduction of his wife. This action lay at the common law; and thereby the husband shall recover, not the possession of his wife, but damages for taking her away: and by statute Wiltm. 1. 3 Edw. 1. c. 13, the offender shall also be imprisoned two years, and fined at the pleasure of the king. Both the king and the husband may, therefore, have this action; and the husband is also entitled to recover damages in an action on the oaf against such as persuade and entice the wife to live separate from him, without a sufficient cause.

Sometines it is also used in the fame sense as rapes; which see.

Ravishment de Gard, is a writ which anciently lay, and still lies, for the guardian in foage against him who took from him the body of his ward, or pupil: but then he must account to his pupil for the damages he has recovered. It is expressly provided by statute 12 Car. II. c. 24, that temporary guardians may maintain an action of ravishment, or trelpeas, for recovery of any of their wards, and also for damages, to be applied to the use and benefit of the infants.

RAVITZ, or RAVITZCH, in Geography, a town of the duchy of Warsaw, molt of the inhabitants of which are Lutherans: it has a considerable manufacture of cloth; 24 miles S. of Polen.

RAVIUS, or RAVE, CHRISTIAN, in Biography, a learned German Orientalist, was born at Berlin in the year 1613. From a very early period he was attatched to the study of the eastern languages, and after spending eight years in different universities on the continent, he came over to England in the year 1648, and took up his residence at the university of Oxford. He brought with him recommendations from Vossius, and other learned men; and was invited to Dublin by archbishop Usher, primate of Ireland, who settled upon him a handsome stipend, and engaged him to take a voyage into the East, for the purpose of collecting ancient manuscripts. About the same time he was invited by cardinal Richelieu to enter into his employment for a similar purpose, which he declined, having already accepted the propofals of Usher. In 1639 he became acquainted with our countryman, the learned Edward Pococke, at Constantinople, where he improved himself in many languages, to which he had already applied his talents; and made himself master of the Turkish, Arabic, and Persian languages. In the mean time he did not neglect the main object of his mission, but collected more than 300 choice manuscripts. For this service he was, on his return, amply rewarded. In 1642 he taught the Oriental languages at Gratham college, in London. During the following year he went to Holland, and was appointed professor of the Eastern languages at Utrecht. We find him again in England in 1648, when he took the covenant, and was made fellow of Magdalen college, Oxford, by the parliamentary visitors. In the course of a few months he left England, and went to Sweden, where he obtained the appointment of professor of the Oriental languages at the university of Upsal.

This place he was obliged to leave about the year 1657; the revenues, that ought to have been devoted to the Upsal professors, having been applied towards defraying the expences of the war between Sweden and Denmark. After this he for some time filled the chair of Oriental literature at the university of Kiöf, and from thence he removed to occupy the professorship at Frankfort on the Main. He died in 1677, about the age of 64. His works are very numerous, of which the following are titles of the principal: "Observation ad univerfam Europam pro dicendis Rebus et Linguis Orientalibus, ac congregation Africa atque Asia Eruditione," 1644; "Orthographiae et Analysis vulgo etymologiae Ebraicae Delineatio, juxta vocis partes abftractas," "A Discourse of the Oriental Tongues, viz. Hebrew, Samaritan, Chaldee, Syriac, Arabic, and Ethiopic," 1640; "Concordianiarum Hebraicarum et Chaldaicarum Epitome;" "Chronologia Biblica nova;" "Epitophes variar 2d. doct. Viro." He gave also to the world a translation, from the Arabic language, of Apollonius's Conic Sections. He had a brother, named John Ravius, who was professor of philosophy at Refoock, about the year 1638. In 1664-5 he was appointed counsellor and librarian to the elector of Brandenburg. He was author of "Commentarium in Corneum Nepotem," 1635; "Summa Studiorum pro Nobilitate Danica;" "Aphorismi Militares," and other learned works.

RAULIN, JOHN, a French writer in the 15th century, was born at Touli in the year 1443. He pursued his studies at the university of Paris, where he obtained the degree of D.D. in 1480, and afterwards filled the professor's chair in theology with great distinction. He was elected grand master of the college of Navarre, and founded a good library in that feminary. Becoming disaffected with the world, he embraced the monastic life at the abbey of Chant, in Burgundy, in 1497. He died in 1514, at the age of 71. He attracted much attention as a preacher, and several of his sermons have been published, which exhibit striking specimens of the bold style which prevailed in France in the 15th century. The works of this author were collected, and published at Antwerp, in 6 vols. 4to., 1612. They are accompanied with a curious and valuable collection of "Letters," that illustrate the history, manners, and sentiments of the age in which he lived. They were first published after his death, in quarto, in 1521, under the title of "Joannis Raulini Epitopholium Viroorum." More.

RAULT, FELIX, the favourite performer on the German flute at Paris, in 1770; where we heard him ourselves as much pleasure as a flute can give, by neat execution, perfect intonation, and a mellifluous embouchure. M. Laborde has rendered his biographical article interesting by a detail of his professional merits and private character.

"M. Felix Rault was born at Bourdeaux, in 1736. He was the son of Charles Rault, of the king's band, and first balloon at the opera. Felix was received there in 1753, and in the king's band in 1768. His talents are so well known at Paris, as to be above praise. Since Blavet's time, no one has brought the art of playing upon the German flute to such perfection, especially in accompanying the voice; a much more difficult art than playing concertos of great execution, generally well studied at home previous to performance. But such study is useless to Rault; for no
one reads music more readily and with more facility, or gives it more meaning, than this performer. The beauty of his tone, the precision of his execution, the richness of his embouchure, however extraordinary, merit still less praise than his personal qualities, which endear him to all his acquaintance." Laborde.

RAUMO, in Geography, a sea-port town of Sweden, in the province of Finland, on the E. coast of the gulf of Bothnia: 50 miles N. of Abo.

RAUNPIKED, in Rural Economy, a provincial word used to signify flag-headed, among trees, as an old overgrown oak, having the limbs of the boughs standing out.

RAURAH, in Geography, a town of Thibet; 26 miles N. of Jemlah. N. lat. 31° 2'. E. long. 81° 40'.

RAURAVA, a Sanerit word meaning dreadful, and a name of one of the Hindoos hells; they reckoning twenty-one of these receptacles for sinners. Naraka is called Maharrurava, or most dreadful.

RAURIS, in Geography, a town of the archbishopric of Salzburg; 32 miles S. of Salzburg.

RAUSCHENBERG, a town of Hesse; 4 miles N. of Marburg. N. lat. 50° 53'. E. long. 8° 53'.

RAUSCHENBERG, a town of Germany, in the principality of Cumbach; 7 miles N.N.E. of Neuntadt.

RAUSNITZ, a town of Moravia, in the circle of Brunn; 10 miles E. of Brunn.

RAUTA LAMBI, a town of Sweden, in the government of Kuopio; 27 miles S.W. of Kuopio.

RAUTENBURG, a town of Prussian Lithuania; 27 miles W. of Tilsit.—Alfo, a town of Prussia, in the province of Samland; 36 miles N.E. of Königsberg.

RAUTERN, a town of Austria; 6 miles W.N.W. of Drofendorf.

RAUTIO, a town of Sweden, in the government of Uleå; 36 miles S. of Braheлад.

RAUTPOUR, a town of Hindooftan, in Allahabad; 18 miles N.N.W. of Corah.

RAUTY Dungaree, a town of Hindooftan, in Guzerat, on the coast; 50 miles S.W. of Nozangur.

RAUTY-Mummy, or Rauty-adumum, bone-mummy, a name given by the people of the East Indies to a kind of fossil substance, much valued for its medicinal virtues. It is of the nature of the leaves, and is found upon the high rocks, and supposed to be generated of the dew which falls from the heavens; but this is an idle opinion, and the formation of it is evidently the same with that of the European rhomboidal fenites. They beat it to powder, and after boiling it in milk, they give it in cafes of the venereal kind. In a common clasp, they give half a scuffle, night and morning.

RAUVEE, in Geography, a river of Afsa, which rises on the borders of Thibet, and joins the Chunaub in the country of Lahore, 28 miles N.E. of Moutlan. The Rauvee is the "Hydroses" of Alexander, and though it is represented as a noble river, it is somewhat inferior in bulk to the Chunaub. Its sources are in the mountains near Nagorkote, a famous place of Hindoo worship; and it enters the plains near Shahpour (called alfo Rajapour), from whence the famous canal of Shah Nahr was drawn to Lahore, 413 common coves in length. The space between the Rauvee and Chunaub, at their entry on the plains, is about 5 geographical miles; and they gradually approach each other during a course of 170 miles. The junction of the Rauvee with the Chunaub (or rather the Chunaub and Behut collectively) is effected nearly midway between Teouomba and Moutlan. The Ayin Acheere allows 27 coves between the junction of the Behut and Chunaub, and that of the Rauvee with the Chunaub; but this distance must be applied to the course of the river, not to the road by land. When these three rivers are united, they form a stream equal to the Indus itself, at the place of confluence; which is from 20 to 30 miles below Moutlan.

RAUWOLFIA, in Botany, was so named by Pluemer, in memory of Leonard Rauwolf, a native of Augsburg, and a pupil of Rodelet. He failed from Marfelles, in 1573, for the Levant, and performed a laborious and dangerous journey through Syria, Mesopotamia, Palatine and Egypt; of which he has left an account in German, full of curious information relative to medical and other rare plants, with several wooden cuts. He died physician to the Austrian army, at Hatvany, in Hungary, in 1666, according to Dryander, Bibl. Banks, v. 395, though Haller says 1566. The latter writer mentions his being obliged to quit his country on account of his religion, which was Protestant. His splendid herbarium, once the property of queen Chefilina, and of Isaac Volfius, is preferred in the university of Leyden. From it Geronovius composed his Flora Orientalis.—Linn. Gen. 115. Schreb. 160. Willd. Sp. Pl. v. 1. 1217. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 64. Juff. 148. Plum. Gen. 19. t. 40. Lamm. Illustria, t. 172. Gernet. t. 52.—Clas and order, Pentandria Monogynia. Nat. Ord. Contorta, Linn. Apoines, Jull.

Gen. Ch. Cal. Periam inferior, minute, with five segments, permanent. Cor. of one petal, falver-shaped; tube cylindrical, globular at the base; limb in five deep, roundish, emarginate, oblique segments. Stam. Filaments five, shorter than the tube; anthers erect, simple, acute. Pijl. German roundish; style very short; stigma capitulate. Pet. Berry nearly globose, marked with a furrow along one side, of one cell. Seed two, excent on the base, tapering at the summit, comnpact, divided, more or less completely, into two cells.

Eff. Ch. Corolla oblique, falver-shaped. Stamens included. Berry globose, with two seeds, each of two cells.

1. R. niida. Shining Rauwolfia. Linn. Sp. Pl. 303. Hort. Off. 75. t. 9. Willd. n. 1. Ait. n. 1. R. tetraphylla angulifolia; Orch. t. 232. t. 236. f. 1. Leaves in fours, lanceolate, pointed, very smooth and shining. Flowers axillary or terminal, cymose.—Native of mountainous woods in the West Indies. A shrub about twelve feet high, erect, very smooth and shining, abounding with vivid milk. Leaves four together at each joint of the branchlets, spreading, on short stalks, lanceolate, with a blunt point, entire, unequal in size, from two to five inches, or more, with one rib, and many fine transverse parallel veins. Flowers small, white, inodorous, in axillary, rarely terminal, halfed cymes, shorter than the leaves. Fruit, according to Jouquin, at first yellow, then purplish-black, thrice the size of a pea, milky. Linnaeus tells us his figure in the Hortus Cliffortianus was drawn by Ehret, from a plant in the Chelsea garden; so that this Rauwolfia must have flowered under Miller's care, in the year 1736. In Ait. H. Kew, a later date is given. The corolla in the figure just mentioned is more cone-like in the limb, as well as more notched, than Pluemer represents it.

Native of New Spain. The whole plant is smooth. Stem shrubby, a yard high, with plant, round, leafy branches. Leaves scattered, rounded at the base, rather pointed, singleribbed, two or three inches long, on shortish stalks. Flowers small, white, about four together, in small cymes or clusters,
clusters, opposite to the leaves. *Berry* obovate, with only one seed; as least in garden specimens, which very probably differ in those respects from wild ones. This species flowered at Madrid from August to October.

3. *R. canescens*. Hoary Rauwolfa. Linn. Sp. Pl. 353. Willd. n. 3. Ait. n. 2. (R. hissita; Jacq. Amer. 47. R. tetraphylla latifolia; Plum. 232. t. 236. f. 2.)—Leaves in fours, elliptico-oblative, acute, downy. Flowers axillary or terminal. Segments of the corolla obtuse.—Native of dry, funny, bushy places in the West India islands, as well as on the neighbouring continent. It was cultivated by Miller at the same time with the first species. We received a specimen in flower, from the iIove at Kouw, in June 1807. Jacquin says this species varies greatly in the size of all its parts, according to soil and situation, and in the height of its stem from one to eight feet. The young branches, flower-flalks, footstalks, and both fides of the leaves, are clothed with short dense pubescence, which almost entirely disappears by culture, though the upper side of the footstalks continues rough with shrewly glands. The leaves are from one and a half to two inches long, obovate, more or less inclining to elliptical, acute, unequal. *Flowers* in small, axillary, downy, italked tufts, or umbels. *Corolla* green with a tinge of red, its segments obsolete. *Fruit* glazed at the top, bright red, then black, containing two *seeds*, as Jacquin well describes it. One cell of each seed is usually, according to him, abortive.

4. *R. tomentosa*. Downy Rauwolfa. Jacq. Amer. 48. Obl. f. 2. g. t. 35.—Leaves in fours, obovato-lanceolate, downy, tapering at each end. Flowers axillary or terminal. Segments of the corolla acute.—Native of rocky places around Carthagesa; sometimes on the stone walls of the town. Jacquin alone seems to have known this species, which principally differs from the last, as far as we can judge, in having white flowers, the segments of whose corolla are acute and acute. The leaves moreover are rather tapering at each end; but that circumstance varies. *Fruit* the size of a pea, bright red, then black. We have seen no specimen.

5. *R. Pulapatia*. East Indian Rauwolfa. Roxb. MSS.—Leaves in threes, elliptical, bluntly pointed, smooth and shining. Flowers terminal, in forked panicles. Corolla many times longer than the calyx. Sent by Dr. Roxburgh, from Calcutta, with the above name. We rely on him for the genus, having seen no fruit. This *frub* is smooth in nearly every part, with round branches. *Leaves* about three inches long, and above one broad, coriaceous and shining; their transverse veins very fine and numerous. *Flower-flalks* very minutely downy, as well as the imbricated *bracteas*, and keeled pointed segments of the calyx. *Corolla* apparently white, with a red tube, which is near three quarters of an inch long, cylindrical, swelling at the top; segments of the limb rounded.

**Rauwolfa**, in *Gardening*, contains plants of the tender, exotic, shrubby kind for the iIove, of which the species cultivated are: the shining rauwolfa (*R. nitida*); and the hoary rauwolfa (*R. canescens*).

**Method of Culture.**—These may be increased by the seeds or berries, which should be sown in pots filled with light mould, in the autumn or spring, plunging them in a mild hot-bed. When the plants have attained some growth, they should be removed into separate pots, and have the management of other exotic iIove plants. They may likewise be raised by layers and cuttings, laid down or planted out in pots, plunged in the hot-bed in the spring and summer months, till they have thicken root, being afterwards managed as those from seed.

They afford much ornament and variety in hot-house collections, both in their foliage and flowers.

**Rauzzini, Venanzio**, in *Biography*, a native of Italy, who, when he arrived here in 1774, to succeed Millo at the opera, was a beautiful and animated young man, with a sofitrano voice. He was an excellent musician, having studied counterpoint with as much application as the art of singing; so that he may truly be said not only to know his own business, but that of a maestro di cappella; having been as able to compose an opera as to perform a principal part in it. "Piramo e Tifene," and "La Veduta," may be inflamed in proof of this affection.

His voice was not very powerful when he came hither from Munich, where we first knew him; and where he had enjoyed the highest favour several years. His talent, governed by science, was correct and exquisite. His voice, though not of great volume, was sweet, clear, flexible, and extensive; being in compass more than two octaves. But he is supposed to have injured his chfet in early youth by a rage for counterpoint. He played the harpsichord neatly, accompanied well, and had real genius for composition, which inclined him to devote that time to the pen and the improvement of his hand, which, perhaps, in his fitation, would have been more usefully bestowed in nursing and exercising his voice.

It was some time before the extent of his merit and science were known in this country, and favoured by the public. Nothing can so speedily convey the merits of a finger to an audience, as a great and powerful voice. However, his taste, fancy, knowledge, and delicacy, together with his beautiful person, and spirited and intelligent manner of acting, before the first favor was over, gained him general approbation and favour. And since he has quitted the stage, and made Bath his residence. Though he has been long obliged to discontinue singing in public, it is not too much to say that he has diffused the good taste throughout the kingdom, by the numerous scholars he has taught among the nobility and gentry, as well as by those whom he has prepared for public patronage, professionally.

**RAW**, in *Agriculture*, any port of plant, substance, or material, which is in a green, unripe, or undigested condition, or which is employed in its more fresh and crude state; as, for instance, dung before it has been much reduced, and lost many of its nutritive principles or properties by the process of fermentation. See DUNG.

**RAW Cream**, in *Rural Economy*, such as is raised in the natural way, not feuded or clouded.

**RAW Hide.** See *Hide*.

**RAW Lands**, in *Agriculture*, a term applied to wet, cold, heavy lands, which are unfit to receive the feed.

**RAW Silk.** See *Silk*.

**RAWA**, or **Rawa**, in *Geography*, a town of the duchy of Warsaw, late capital of a palatinate of the same name. The castle is appropriated for the confinement of state prisoners; 45 miles S.W. of Warsaw. N. lat. 51° 55'. E. long. 20° 17'.

RAWA, a town of Poland, in the palatinate of Belz; 18 miles S.W. of Belz.

**RAWA.** See Rawa.

**RAWAK**, a small island in the Pacific ocean, near the N. coast of the island of Waygoo, with which it forms a harbour. E. long. 131° 15'.

**RAWAPS KITCHWOCK**, a small westerly branch of Machias river. See *Machias*.

**RAWAY**, or **Bridge-town**, a truly commercial village of Middlesex county, New Jersey, on Rawar river, four or five miles S.W. of Elizabeth-town, and 75 from Philadelphia.
phia. It contains a post-office, a presbyterian church, and about 50 or 60 houses.

RAWDON, a town of Nova Scotia, 40 miles from Halifax, containing about 50 or 60 houses.

RAWDON, a township of the county of Hastings, in Upper Canada, N. of Sidney.

RAWLISON, CRISTOPHER, in *Biography*, of Cork-Hall, in Lancashire, was born in 1657, educated in Queen's college, Oxford, and died in 1733 : he was much attached to Saxon and Northern literature, and published an edition of "King Alfred's Translation of Beothicus de Confolatione," 8vo. 1698.

RAWLISON, RICHARD, a diligent relation of the preceding, a learned antiquarian, was the son of Sir Thomas Rawlinson, knight, and once lord mayor of London. He was educated at St. John's college, Oxford, and was admitted to the degree of doctor of the civil law in 1719. He devoted himself to antiquarian pursuits, and made large collections for a continuation of Wood's *Athenae Oxonienses*, and History of Oxford, and published the life of that industrious antiquary. The principal work of Mr. Rawlinson was "The English Topographer," or, An historical account of all the pieces that have been written relating to the ancient natural history or topographical description of any part of England, 1720. He published the "Latin Letters of Abelard and Heloise," and "A Translation of Du Frevnoy's New Method of Studying History," 2 vols. 8vo. He died at Illington in 1755, and by his will ordered that his heart should be deposited in the chapel of St. John's college, Oxford. That universality was indebted to him for various benefactions of books, manuscripts, medals, &c. as well as landed property, and an endowment for an Anglo-Saxon lecture.

RAWLOW, in *Geography*, a town of Hindooftan, in Palnaud; 27 miles W.S.W. of Timerycotta.

RAY, JOHN, in *Biography*, whom Haller terms the greatest botanist in the memory of man, and to whose transcendent merits we have already briefly adverted, in treating of the genus dedicated by Pliny to his name, see RAIAMIA; was born at Black Notley, near Braintree, in Essex, Nov. 29, 1628. His father, Roger Ray, though in the humble station of a blacksmith, gave him a learned education; first at the grammar-school of his native town, at that time not very well conducted; and subseqently at Cambridge, where he entered at Catharine Hall, in his 16th year, June 28th, 1644, being designed for holy orders. In about a year and three months afterward, he removed to Trinity College, where he found the young men occupied in a more liberal train of studies, with less of scholastic discursions and quibbles. Ray was fortunate in having for his tutor at Trinity, Dr. Duport, an eminent Greek scholar, under whose fostering and partial care, he soon made up for all the deficiencies of his early education, in the learned languages, including Hebrew. By this gentleman he was always mentioned with peculiar regard. He was no less happy in a youthful literary friend and fellow-student, afterwards the celebrated Dr. Isaac Barrow. Even at this early period, Ray began to cultivate natural history; and distinguished himself by many school exercises as an orator, no less than by his general talk for study, his love of virtue, and his gentleness of manners, qualities which thence brighter and brighter to the latest period of his life. His merit occasioned him to be chosen a Minor Fellow of Trinity, along with his friend Barrow, September 8th, 1649. On taking his degree of Master of Arts, he became a Major or Senior Fellow; and afterwards, October 18, 1651, Greek Lecturer of the college. At the end of two years he was appointed Mathematical Lecturer, and in two years more, October 24, 1655, Humanity Reader. He subsequently filled several respectable offices in his college, as Junior Dean, College Steward, &c., and during his residence in the university, became tutor to many gentlemen of rank and fortune, who were sensible of their obligations to him; among whom the most eminently distinguished by personal worth, and congeniality of talents with himself, was Mr. Francis Willoughby, of Middleton-hall in Warwickshire, so well known by his posthumous works on Birds and Fishes, edited by the affectionate care of Ray.

At this period it was usual for young men of ability and learning, though not in orders, to deliver sermons, and common-place readings, as they were called; not only in the chapels or halls of their own colleges, but even before the university body, at St. Mary's church. In these Ray eminently distinguished himself. He was among the first who ventured to lead the attention of his hearers, from the unprofitable subtleties of scholastic divinity, and the trammels of Aristotelian philosophy, to an observation of nature, and a practical investigation of truth. The rudiments of many of his subseuent writings originated in these juvenile effays, particularly his celebrated book on the "Wisdom of God manifested in the Works of the Creation," known all over the world by its numerous editions and translations, and universally admired for its rational piety, found philosophy, and solid instruction. This book is the basis of all the labours of following divines, who have made the book of nature a commentary on the book of revelation; a confirmation of truths, which Nature has not authority, of herself, to establish. In it the author inculcates the doctrine of a constantly superintending Providence; as well as the advantage, and even the duty, of contemplating the works of God. This, he says, is part of the business of a sabbath day, as it will be, probably, of our employment through that eternal rest, of which the sabbath is a type. Archbishop Tenison is recorded to have told Dr. Derham, that "Mr. Ray was much celebrated, in his time, at Cambridge, for preaching sound and useful divinity, instead of that enthusiastic stuff, which the sermons of that time were generally filled with." Two of his funeral discourses are mentioned with particular approbation; on the death of Dr. Arrowsmith, master of his college; the other on that of one of his most intimate and beloved colleagues, Mr. John Nid, likewise a Senior Fellow of Trinity, who had a great share in Ray's first botanical publication, the "Catalogue Plantarum circa Cantabrigiam nuditentum;" printed in 1658; which may be considered as the prototype of his *Synopsis*, hereafter mentioned. Indeed before this little volume appeared, its author had visited various parts of England and Wales, for the purpose of investigating their native plants, as he did several times afterwards; nor were his observations confined to natural history, but extended to local and general history, antiquities, the arts, and all kinds of useful knowledge. His amusing Itineraries were published, along with his life, by Dr. Derham, and a few letters to that gentleman, by the care of Dr. George Scott, F.R.S., in 1760, under the title of "Select Remains of the learned John Ray, M.A., &c." Ray's first botanical tour occupied nearly six weeks, from August 9th to September 18th, 1658. On the 23d of December 1660, he was ordained, both deacon and priest at the same time, by Dr. Sanderson, then bishop of Lincoln. In 1661 he travelled with Mr. Willoughby into Scotland, returning by Cumberland and Westmoreland; and the following year, with the same companion, he accomplished a more particular investigation of Wales. How critically he studied the botany of the countries
countries he visited, is evident from the different editions of his *Catalogus Plantarum Angliae*, and *Synopsis Methodica Stirpium Britannicarum*.

All this while Mr. Ray continued to enjoy his fellowship, and to cultivate his Cambridge connections; but in September 1662, his tranquillity was disturbed by the too famous Bartholomew act, by which 2000 confecutively divines were turned out of their living, and many fellows of colleges deprived of their maintenance, and means of literary improvement. Among the latter was the subject of our memoir, with thirteen honest men at Cambridge besides, of whose names he has left us a list. One of them, Dr. Dillingham, was master of Emanuel college; but Ray was the only perchon of his own college who suffered this deprivation. The reader must not suppute that he, or perhaps any other perchon in this illustrious catalogue, was, in the least degree, deficient in attachment to the doctrine or discipline of the church of England, or that they had taken the oath called the Solemn League and Covenant; which Ray certainly had neither taken nor ever approved. They were required to swear to the infamous proposition, that the said oath was not binding to those who had taken it, and on this ground did not voluntarily give up their preferment. It is curious to read the apology made for Ray by Dr. Derham, on this subject, by a Mr. Brokefly, that he was at that time absent from his college, when he might have met with satisfaction to his feruples, and was among some zealous non-conformists, who too much influenced him, by the addition of new feruples. And we may also ascribe somewhat to the prejudice of education in unhappy times. By this it appears, that the “feruples” of non-conformists were most favourable to the sanctity of an oath; and that the “unhappy times” alluded to, were more advantageous to principle, than the golden days of Charles II.; whose minders doublets valued the obedience, far more than the honesty, of any man; nor is this taint, by any means, peculiar to them or their profligate matter.

Mr. Ray, or, as he wrote his name, for a while, about this period, Wray, having thus the world before him, made an arrangement with Mr. Willughby for a tour on the continent; and in this plan two of his pupils were included, Mr. Nathaniel Bacon, and Mr., afterwards Sir Philip, Skippon. They failed for Calais in April 1663, but being prevented, by the flat of political affairs, from prosecuting their journey through France, they traversed the Low Countries, Germany, &c. proceeding by Venice into Italy; most of whose cities they visited, either by sea or land; as well as Malta and Sicily; and returned, by Switzerland, through France, into England, in the spring of 1666. Mr. Willughby indeed separated from the rest of the party at Montpellier, and visited Spain. An ample account of their observations was published by Ray, in 1673, making a thick octavo volume. The travellers appear to have been diligent and acute in every thing relative to politics, literature, natural history, mechanics, and philosophy; as well as antiquities and other curiosities; but in the fine arts they assume no authority, nor display any considerable taste or knowledge. Mr. Willughby’s account of Spain makes a part by itself; and a rich critical catalogue of such plants, not, for the most part, natives of England, as were observed in this tour, concludes the volume. Haller gives to Ray the credit of having discovered several species in Switzerland, previously not known as natives of that country.

Ray palled the summer of 1666 partly at Black Notley, and partly in Suffolk, studying chiefly the works of Hook, Boyle, Sydenham on Fevers, and the Philosophical Transactions, “making few discoveries,” says he, “five of mine

own errors.” The following winter he was employed at Mr. Willughby’s, in arranging that gentleman’s museum of natural history and coins, and in forming tables of plants and animals for the use of Dr. Wilkins, in his famous work on an Universal Character. He now also began to arrange a catalogue of the English native plants, which he himself had gathered; rather for his own use, than with any immediate view of publication; “at present,” as he wrote to Dr. Lifter, “the world is glutted with Dr. Merrett’s bungling Pinnax. I resolve never to put out any thing which is not as perfect as is possible for me to make it. I wish you would take a little pains this summer about grafts, that so we might compare notes.” The above refolution of our author is, no doubt, highly commendable, but the world has rather to lament that so many able men have formed the fame determination, at least in natural science. If it were universally adhered to, scarcely any work would fee the light; for few can be so fensible of the defects of any other perchon’s attempt to illustrate the works of nature, as a man of tolerable judgment must be of his own. This is especially the case with those who, like Ray, direct their aspirings views towards fytlem, and philosophical theory. Happily, he has lived to acquire a firft rank, and trained himself by wholefome practical discipline, in observation and experience. His firft botanical works assumed the humble form of alphabetical catalogues. His and Mr. Willughby’s labours in the service of bishop Wilkins, were indeed of a fystematical defcription; and accordingly the authors themselves were, more than any other perchon probably, diftisfied with their performance. They relaxed from these labours in a tour of practical observation through the west of England, as far as the Land’s-End, in the summer of 1667, and returning by London. Mr. Ray was solicited to become a Fellow of the Royal Society, into which learned body he was admitted November 7th. Being now requested by his friend Wilkins to translate the “Real Character” into Latin, he undertook, and by degrees accomplished, that arduous performance, depositing his manuscript in the library of the Royal Society, where it has ever since reforted. The following summer was agreeably spent, in visits to various literary friends, and in a folitary journey to the north; for his former companion Willughby, being just married, stayed at home; there Ray joined him in September 1668, and remained for most part of the ensuing winter and spring.

The seclusion and leisure of the country, with the converse and affifiance of such a friend, were favourable to the prosecution of a new subject of enquiry, which now strongly attracted the attention of our great naturalist, the theory of vegetation. The firft step of the two philosophers, in this little-explored path, was an examination of the motion of the sap in trees; and the refult of their enquiries, communicated to the Royal Society, appeared soon after in the Philosophical Transactions. Their experiments clearly prove the acfent of the sap through the woody part of the tree; which is easily detected by boring the trunk, at different depths, before the leaves are unfolded; and they observed also the muclaginous nature of the flowing sap, “precipitating a kind of white coagulum or jelly, which,” says Ray, in a note preferred by Dr. D’Hain, “may be well conceived to be the part which, every year, between bark and tree, turns to wood, and of which the leaves and fruit are made. It seems to precipitate more when the tree is just ready to put out leaves, and begins to cease dropping, than at its first bleeding.” The accuracy of the leading facts recorded by these ingenious men, is confirmed by subsequent observers, who have further purified the same subject, which is now sufficiently
sufficiently well understood. They indeed, like the rest of the world till lately, seem not to have suspected, that the sap was quiescent till their perforations in the tree were made; nor did they advert, as they ought, to phenomena dependent on the principle of life, in the vegetable body. See Circulation of the Sap.

At this time Ray began to prepare for the press his "Collection of Proverbs," a curious book in its way, by which he is perhaps better known to the generality of his countrymen, than by any other of his literary labours. The first edition was published in 1672; but the work was subseqently much enlarged, and the author may almost be said to have exhausted his subject. From its very nature, delicacy and refinement must often be dispensed with; but this is evidently not the fault, or the aim, of the writer. His learned and critical acuteness diffuse light over the whole, and make us overlook the coarse vehicle of its instruction.

The first edition of the Catalogue of English Plants, already mentioned, came out in 1670, and the second in 1677. Their great author gave his work to the world with that deference, for which he alone perhaps could perceive any just foundation. We postpone our remarks till we speak of the same work in its systematic form hereafter.

About this period the health of Mr. Ray seems to have been considerably impaired. He refused a tempting offer to travel again on the continent, as tutor to three young noblemen; nor could the powerful attractions of alpine botany, which made a part of his prospect, overcome the reluctance to leaving home, which arose from a feeble state of body. Indeed this very reluctance, or littlefome, is accounted for, by the turn which his disorder took, as it terminated in the jaundice. After this depressing complaint had left him, he refused, with fresh alacrity, his botanical travels at home; visiting the rich flores of the north of England, with a companion named Thomas Williel, whose name and discoveries afterwards, on many occasions, have gratefully commemorated. Nothing formed a more striking feature in Ray's character, than the unrestrained and abundant commendation, which he always gave to his friends and fellow-labourers. We are about to narrate an event, which called forth all his affectionate feelings of this kind, as well as his most important and beneficial exertions; when, even to his own prejudice, he fulfilled the sacred duties of friendship, and delighted in adorning the bust of his friend with wreaths, that he himself might have adorned. On the 3d of July 1672, Mr. Williugby was unexpectedly carried off by an acute disorder, in the 37th year of his age. The care of his two infant sons was confided by himself to Mr. Ray, who was also appointed one of his executors, and to whom he left an annuity of 60l. for life. The eldest of these youths was created a baronet at the age of 10 years, but died before he was 20. Their father Caiannard afterwards married the duke of Chandos. Thomas, the younger son, was one of the ten peers created, all on the same day, by queen Anne, and received the title of lord Middleton. His early youth was much indebted to the care of his faithful guardian, who composied, for his and his brother's use, and published in 1672, a Nomenclator Castorum, far more exact, especially in the names of natural objects, than any that had previously appeared. The care of his pupils, and of the literary concerns of their deceased parent, now interrupted Mr. Ray's botanizing excursions, and caused him also to decline the offer of Dr. Liller, then a physician at York, to settle under his roof. Bishop Wilkins did not long survive Mr. Williugby, and his death made another claim in the scientific and social circle of our great natural philosopher, who felt these losses as deeply and tenderly as any man. He sought consolation in a domestic attachment, fixing his choice on a young woman, of good parentage, whose name was Margaret Oakeley, and who resided in the family at Middleton-hall. He was married at the parish church, June 5th, 1673, being then in the 45th year of his age, and his bride about 20. This lady took a share in the early education of his pupils, as far as concerned their reading English. She is said to have been recommended by her character, as well as her person, to the regard of her husband. She bore him three daughters, who, with their mother, survived him.

Ray's communications to the Royal Society became now very frequent, and extended to various subjects relative to the natural history of animals, as well as to the physiology, and even the botanical characters, of vegetables. He was, at the same time, in the course of the years 1674 and 1675, much occupied in digesting Mr. Williugby's zoological papers. These were composed in Latin, in which language the Ornithology first appeared in 1676, making a folio volume, accompanied by 77 plates, engraved, at the expense of the author's widow, from his own drawings. An English translation by Ray, with still more additions than he had supplied to the former publication, and one more plate, issued from the press in 1678. The account which Dr. Derham received from the lips of Mr. Ray, about eight months previous to his decease, respecting the primary intentions of himself and his late friend, and which is recorded in his life, p. 48, is too curious to be omitted here, as their project and its execution form an epocha in the history of natural science. "These two gentlemen," says Derham, "finding the history of Nature very imperfect, had agreed between themselves, before their travels beyond sea, to reduce the several tribes of things to a method; and to give accurate descriptions of the several species, from a strict view of them. And forasmuch as Mr. Williugby's genius lay chiefly to Animals, therefore he undertook the Birds, Beasts, Fishes, and Insects, as Mr. Ray did the Vegetables." Derham adds, that Mr. Williugby, during his short life, "prosecuted his design with as great application, as if he had been to get his bread thereby." The writer of the present article has elsewhere observed, (Introductory Discourse, Tr. of Linne Soc. v. i.) that "from the affectionate care with which Ray has cherished the fame of his departed friend, we are in danger of attributing too much to Mr. Williugby, and too little to himself." His own statement, no doubt, was correct, as to their original aims; but it is impossible not to perceive that the survivor executed or perfected what his friend, in many instances, could only have projected, or fearfully begun. Had Williugby lived, there can be little doubt of his career being as glorious in the sequel as that of his friend; and possibly, from the advantages of fortune which he enjoyed, even more widely beneficial to science. Yet who can tell that he might not have thickened his course? Though he gloriously avoided the flares of luxury and folly in his youth, who shall say that politics or ambition might not have dazzled his ripen age? or that he would always have eluded that remote vanity, which grasps at universal knowledge, or rather at universal fame; and knowing nothing deeply, is most flattered with any praise which is least deserved. So often has this laft been the case with literary men, that one cannot but mistrust a character of the fairest promise. What Ray has done, we know and can appreciate. Equal to his friend in learning, talents, and zeal, the advantages of ample fortune were compensated by the leisure and tranquillity of a sequestered country life. His duties
went hand in hand with his studies and recreations, and he enjoyed, as Haller observes, the rare felicity of giving 50 years uninterruptedly to his favourite science. His long-protracted studies, and ripe experience, enabled him to achieve what at first he could but regard at a distance, as the great object of his wishes, a systematic arrangement of the animal as well as vegetable kingdoms. Every body had, hitherto, been content with Aristotle's classification of animals, of whose imperfections Ray, daring to think for himself, could not but be aware. He invented a new one, founded on the structure of the heart. "The Harveian experiments, and doctrine of the circulation, had called the peculiar attention of philosophers to every organ which has a share in that phenomenon; and to this cause, probably, we owe the method of Ray." The mode of breathing in animals, whether by lungs or by gills, and the single or double structure of the heart, in the former case, constitute the basis of his system; which, in these particulars at least, succeeding naturalists have adopted. His subordinate characters of the principal classes exercise great skill and sagacity, and the Linnaean system of Quadrupeds is highly indebted to that of our illustrious countryman.

His zoological publications indeed did not follow each other in rapid succession; for after the Ornithology had come forth in English, eight years elapsed before the Histrio Pictorum of Willughby was given, by his care, to the world. This was printed in folio, with 188 plates of figures; in 1686, at Oxford, owing to the interest of bishop Fell, and the pecuniary assistance of the Royal Society. It does not appear why the title of Mr. Willughby withheld, in this instance, the contributions which had to much benefited his husband's former work, and which he justly owed to his fame. It seems that the intimate connexion of Ray with this family, was much impairing by the death of lady Caffandra Willughby, the mother of his friend, about the year 1675 or 1676; when the children were taken from his tuition, and he left Middleton-hall, fixing for a short time at Sutton Cotefold, four miles distant. At Michaelmas 1677 he removed from thence to Falborne-hall, in Essex, not far from his native village. On the 15th of March following, his mother, at the age of 78, died at Black Notley, "in her house on Dewlands," of whom he speaks with that reverence and regret, which has peculiarly marked the characters of some of the greatest and best men on the same occasion. At Midsummer 1679, he finally settled at Black Notley, for the remainder of his days, or "for the short pittance of time he had yet to live in this world," as he himself expressed it; which pittance, however, extended to more than twenty-five years.

The first fruit of our author's leisure and retirement was his Methodus Plantarum Nova, published in 1682, making an octavo volume. His principles of arrangement are chiefly derived from the fruit. The regularity and irregularity of flowers, which take the lead in the system of Rívius, make no part of that of Ray. It is remarkable that he adopts the ancient primary division of plants, into trees, shrubs, and herbs, and that he blamed Rívius for abolishing it, though his own prefatory remarks tend to overtake that principle, as a vulgar and casual one, unworthy of a philosopher. That his system was not merely a commodious artificial aid to practical botany, but a philosophical clue to the labyrinth of Nature, he probably, like his fellow-labourers, for many years, in this department, believed; yet he was too modest, and too learned, to think he had brought this new and arduous design to perfection; for whatever he has incidentally or deliberately thrown out, respecting the value of his labours, is often marked with more diligence on the subject of classification, than any other. He first applied his system to the practical use in a general Histoia Plantarum, of which the first volume, a thick folio, was published in 1686, and the second in 1687. The third volume of the same work, which is supplementary, came out in 1694. This will and critical compilation is still in use as a book of reference, being particularly valuable as an epitome of the contents of various rare and expensive works, which ordinary libraries cannot possess, such as the Hortus Malabaricus. The description of species is faithful and instructive; the remarks original, bounded only by the whole circuit of the botanical learning of that day; nor are generic characters neglected, however vaguely they are assumed. Specific differences do not enter regularly into the author's plan, nor has he followed any uniform rules of nomenclature. So ample a transcript of the practical knowledge of such a botanist, cannot but be a treasure; yet it is now much neglected, few persons being learned enough to use it with facility, for want of figures, and a popular nomenclature; and those who are, seldom requiring its assistance. A more catalogue or index, like the works of Tournefort and Cipar Bawjin, which teach nothing of themselves, are of reader use. The Species Plantarum of Linnaeus unites the advantages of the clearest most concise specific definition, and, by the help of Bawjin, of a universal index.

But if the fame or the utility of Ray's great botanical work has, neither of them, been commensurate with the expectations that might have been formed, a little octavo volume, which he gave to the world in 1696, amply supplied all such defects, and proved the great corner stone of his reputation in this department of science. We speak of the Synopsia Methodica Stirpium Britannicarum. The two editions of this alphabetical catalogue of English plants being fold off, and some pettiforging reasons of his book-feller's standing in the way of a third, with any improvements, he re-modelled the work, throwing it into a systematic form, reviving the whole, supplying generic characters, with numerous additions of species, and various enumerations and remarks. The uses and medicinal qualities of the plants are removed to the alphabetical index at the end. A second edition of this Synopsia was published in 1696, nor did its author ever prepare another. The third, now most in use, was edited twenty-eight years afterwards by Dillenius. (See that biographical article.) Of all the botanical and practical Floras of any country, the second edition of Ray's Synopsia is the most perfect that ever came under our observation. "He examined every plant recorded in his work, and even gathered most of them himself. He investigated their synonyms with consummate accuracy; and if the clearness and precision of other authors had equalled his, he would scarcely have committed an error. It is difficult to find him in a mistake or misconception respecting Nature herself, though he sometimes misapprehends the bad figures, or lame descriptions, he was obliged to copy." Tr. of Lin. Soc. c. 4. 277. Above the number of new species are added, in this second edition, and the cryptogamic plants, in particular, are more amply elucidated. A controversial letter from Rívius to Ray, and its answer, with remarks upon Tournefort, are subjoined to this second edition. Much of the dispute turns upon the now obsolete distinction of plants, in a methodical system, into trees, shrubs, herbs, &c. The letters are well written, in Latin: and liberal, though perhaps hypercritical, in their style. Ray took no delight in controversy. Its inevitable
evitable aspersities were foreign to his nature. We must not omit to notice that, in the preface to both editions of his *Synopsis, the learned author, ventures to his character, his talents, and his profession, as well as by his noble adherence to principle in the most corrupt times, has taken occasion to congratulate his country, and to pour out his grateful effusions to Divine Providence, in a style worthy of Milton, for the estabishment of religion, law, and liberty, by the revolution which placed King William on the throne. An honest Englishman, however retired in his habits and his pursuits, could not have withheld this tribute at such a time; nor was any loyalty ever more perfectly disinterested than that of Ray.

The year 1690 was the date of the first publication of his noble work on "The Wisdom of God in the Creation," of which we have already spoken, and whose sale, through many editions, was very extensive. In 1700 he printed a book, more exclusively within the sphere of his sacred profession, called "A Persuasive to a Holy Life."" a rare performance of the kind, at that day, as it would be at the present. The language is devout, enthusiastic, poetic, or caple, as well as of religious bigotry or partisanship, but employing the plain and solid arguments of reason, for the sake of purposes." His three "Physico-Theological Discourses, concerning the Chaos, Deluge, and Disolution of the World," of which the original materials had been collected and prepared formerly at Cambridge, came out in 1692, and were reprinted the following year. A third edition, superintended by Derham, was published in 1713. This able editor took up the same subject himself in a similar performance, the materials of which, like Ray's, were first delivered in sermons, at Bow church, he having been appointed reader of Mr. Boyle's lectures.

While Ray was from time to time intent on these moral and religious performances, in which he laboured equally to impress and elucidate the truths of natural and revealed religion, as well as to enforce its precepts and duties, he was no less attentive than formerly to his systematical studies. Dr. Tanser Robinson is recorded by Derham, as having first prompted our great naturalist to undertake a *Synopsis Methodica or clausal arrangement, of the whole animal, as he had done of the vegetable, kingdom. He even wished him to extend his attention to plants, anticipating, in short, what Linnaeus afterwards performed. Nor did he shrink from the task. Though now for some time oppressed with bodily infirmity, and particularly with those troublesome ulcers in his legs, his mind was tranquil and unimpaired. He soon finished his *Synopsis Methodica Animalium Quadrupedum et Serpantin Genes, which came out in 1693, making a thin, but closely printed, octavo volume. We have already spoken of the originality of his method. The volume in question, however, is not confined to dry systematical arrangement. It enters deeply into the general and particular history of animals, their external forms, and internal structure, with abundance of entertaining and curious facts and observations. Linnaeus was possessed of this book from the year 1734, and appears to have studied it well. A similar volume on birds, and another on fishes, were prepared by the author; but the manuscripts of these lay neglected in the hands of some careless or ignorant bookseller, till they were discovered by Dr. Derham, and published in 1713. They contain more of particular descriptions and histories, than of general remarks; but otherwise accord with the plan of the Synopsia of Quadrupeds. Many things are supplied from materials obtained since the publication of Willughby's Ornithology and Ichthyology, and several figures of fishes were added by Derham, at the perfusion of Petiver, whose works they somewhat resemble.

Having accomplished so many great and laborious publications, our venerable naturalist began, as Dr. Derham informs us, to enjoy the thoughts of repoule from his labours. He was nevertheless ready, at the call of his friends, to revile a translation of Rauwolf's Travels, the original having even then become very scarce, besides being unintelligible to mere English readers. This translation, with some other rare tracts annexed, and a catalogue of Greek, Syrian, Egyptian, and Cretan plants, drawn up by Mr. Ray, issued from the press in 1693. See Ray.

Possibly the *Stirpium Europaeorum extra Britannias afoecen- trum Syllage, which appeared in 1694, originated in the author's attention being recalled, by the last-mentioned publication, to the contemplation of exotic plants. In this volume he collects from Clusius, Bauhin, Columa, and others, various additions to his own discoveries, and the whole are disposed in alphabetical order. A geographical arrangement of the plants, which he had himself gathered in his foreign travels, is introduced; and the volume concludes with alphabetical catalogues, selected from Boconone's Sicilian plants, and other recent authors. It is in the preface to this book, that he first adverts to the fylem of Rivinus, not without just applause of that author's work, a copy of which had been presented to Ray. He commends the apt distribution of the genera, the clearness of the arrangement, the purity of the Latin, and the beauty as well as exactness of the plates. He, however, contends for the ancient distinction of plants into trees and herbs, which, as we have seen, he had himself mentioned as unphilosophical. In the reed of his criticisms, though "much may be said on both sides," and though these controversy, like others, profit of the intricacies and anomalies of Nature, to make good their arguments, concealing themselves, like the cuttle-fish, in their ink; still we cannot but give our testimony to the greater solidity of Ray's principles, as derived from the fruits and seeds of plants, than to the seemingly more elegant ones of Rivinus, deduced from the flower; which, if undoubtedly lead, in their practical application, to some paradoxical combinations. But on this subject we may say more in its proper place. (See Rivi- nus.) In this preface Ray points out the importance and use of the flamens and pitills, succinctly explaining the sexual doctrine, as now universally admitted.

One advantage arose from the epitaphial alteration of Ri- vinus and Ray, that it led the latter to revive his own system, and to republish it, in an improved state. Happy if such were more generally the fruit of contention, that each party should correct himself, instead of aggravating the defects of his adversary. Some notice is taken, in the preface to this edition, both of the system of Tournedot and that of Hermann, which latt was most congenial to the principles of Ray. The work was finished in 1698, but not given to the public till 1703, recourse having been had to a Dutch bookseller, who thought it for his interest to place an English publisher's name in the title-page; a proceeding which, however harmless, shocked the honest feelings of the author; and this perhaps excited the thisty Hollander's sur- prise. By his exertions, however, the book, and the fame of its author, became more widely diffused, and continental botanists were much further inducted into Ray's system than they had previously been.

But now the mortal career of this eminent man was drawing towards a close. He complained in his letters, that, so far from being able to visit the London gardens, as he wished,
in order to make observations upon plants, for the greater perfection of this last edition of his Methodus, he was not able to walk into his neighbouring fields. He still, nevertheless, kept up to the last his correspondence with his friends, in the vivacity and clearness of style which was natural to him. Latin and English, it is said, were equally ready to his pen. So indefatigable was he in the cultivation of the study of Nature, that within a year or two of his death, he began to collect his scattered notes for a work on Insects, and actually drew up a Methodus Insectorum, which was printed, soon after his decease, in a little octavo of sixteen pages, and republished in the front of his Hiftoria Insectorum. This last book, comprising all his observations and Mr. Willowby's descriptions of insects, came from the press in 1716, at the expense of the Royal Society, and under the superintendence of Dr. Derham. It consists of 375 quarto pages, besides an appendix of twenty-three more, on British Beetles, by Linch, Ray attributes to Willowby that part of his system which concerns insects supposed to undergo no metamorphoses. These are mostly the optera of Linnaeus, excluding the exoptera, but admitting the fossil forms of spiders, earth-worms, and leeches. All the descriptions and remarks of his departed friend are marked with the initials F.W. This work is a mass of accurate and authentic observation; but, for want of plates, has never come into popular use. Linneaus studied it much, and has often cited the descriptions, the appropriation of which is, however, too difficult and uncertain to render them of general or extensive service. Those which regard the Le- pidoptera, and their caterpillars, are most copious.

The study of insects was probably the last that engaged the attention of this great and wise man; who, though on the verge of eternity, in the full possession of himself, and in the anticipation of the most glorious manifestations of his Creator, did not disdain or neglect to contemplate him in his least and lowest works. Such an example might serve for an occasional answer to those who affect to think the study of any of the works of God below the dignity of their philosophy; for the most inordinate vanity must look with respect on what formed the abstruse studies of so distinguished a person as Ray. His last letter to Dr. Derham, who had just been to visit him, is dated Augst. 16, 1724. He speaks of having lately obtained Mr. Willowby's entomological papers, and defines himself as then entering on his History of Insects. How well he employed his time during the autumn, is evident from what we have related concerning this work, for he never saw another spring. He died at Black Notley, in a house of his own building, Jan. 27, 1735, in the 77th year of his age. His character is thus concisely given by Derham. "In his declining, no man more strictly just; in his conversation, no man more humble, courteous, and affable; towards God, no man more devout; and towards the poor and distress'd, no man more considerate and charitable, according to his abilities." The friend who wrote this eulogy, in his "Life of Mr. Ray," adds, that he was buried, according to his own desire, in the church of Black Notley; but the authors of the Biographia Britannica are probably more correct, in saying, that he declined the offer made him by the rector, of a place of interment in the chancel, choosing rather to repose with his ancestors, in the church-yard. He perhaps thought, with bishop Hall, that "the house of God ought not to be made a repository for dead carcasses." However this might be, the latter account is confirmed by the original statue of his monument, erected at the expense, in part at least, of bishop Compton. The long and elegant Latin epigraph has often been published. Its author was the Rev. William Coyte, M.A., father of the late Dr. Coyte of Ipswich, and the original manuscript is now before us, containing the information that Ray was interred in the churchyard. In 1737, the monument in question, which seems to have been a fort of altar tomb, being nearly ruined, was re-built at the charge of Dr. Legge, and removed for shelter into the church; where therefore it became a cenotaph, an inscription added on this occasion terms it. Forty-five years afterwards the tomb again underwent a repair, by the care of the present Mr. Thomas Gery Cullum and others, who subjoined a third inscription, as follows:

Tumulum hume, 
a nonnullis humanitati, et scientiae 
naturalis, faventibus, 
cohim conditum, 
et aliorum bona diligentia 
potest reaflauratum, 1737, 
murc e vetustatis fito et foribus 
pauit de novo revocarunt, 1792.

A more lasting monument was dedicated to the memory of our great English naturalist, in the genus of plants which bears his name. (See RANIA.) The opinion we have there, in few words expressed, of his high rank in botanical science, it is hoped the present more diffuse account will justify. It must be lamented that he made, as far as we can learn, no collection of dried plants, which might serve to acent in, in every case, what he described. The great Herbariums of Buddle, Avedale, &c. still kept in the British Museum, are indeed supposed to supply, in a great measure, this defect; they having been collected by persons who had frequent communication with Ray, and were well acquainted with his plants. Whatever he had preferred relative to any branch of natural history, he gave, a few weeks before his death, to his neighbour Mr. Samuel Dale, author of the Phaeno- 
colegia. Nothing is said of his library, which was probably inconsiderable. His peculiar circumstances were very limited, for he merely conformed as a layman to the church of England, and was unwilling to subscribe what was requisite for receiving prebend. He is recorded nevertheless to have disapproved of separatists from the national church; justly disdained, probably, by the contentions and fanaticism he had been throughout the greater part of his life. His principles and feelings soared far above the faddish distinctions, which marked the orthodoxy or the heterodoxy of those times, and his mind was uncontaminated with their passions. His good fortune might well lead him to regret, that those who had so lately escaped a most tremendous common enemy, should be so prone to quarrell amongst themselves. It is an honour to both these parties that they have been emulous to claim him as their ally.

In the preceding review of the literary productions of Ray, more numerous, as Haller says, than those of any other botanist, Linneaus excepted, we have been obliged to pass over several things of less note; such as his lists of native British plants, for Gibbon's edition of Camden's Britannia; and even a variety of communications to the Royal Society. Neither have we touched on the principles of his botanical system, that subject being explained at length by our predecessor, the late Rev. Mr. Wood, under the article CLASSIFICATION. Those who are anxious to peruse a more full and critical investigation of his works and labours, than it has been possible to give in this place, will do well to consult Dr. Pulteney's "Sketches of the Progress of Botany in England." The "Philosophical Transactions," collected and published in 1718, by Dr. Derham, containing 68 written by Ray, and
RAY

many more by his correspondents, throw much light on his character and pursuits. We cannot help remarking that his hand-writing was peculiarly fair and elegant. A specimen of it exists among Sir Henry Spelman's vast and curious collection of manuscripts, now in the possession of John Patterson, esq. late M. P. for Norwich.

The portraits of Ray are not numerous. One in oil, taken at an advanced period of his life, remains in the British Museum, and Dr. John Sims is published of a miniature, of an earlier date, of which its owner has given an engraving, by way of frontispiece to the third edition of the "Annals of Botany," published in 1805. The latter is rather deficient in that strength of character which appears in the more common prints, after a picture by Faithorne, often prefixed to the third edition of the Synopsis, and sometimes to the Historia Plantarum. One of these prints was engraved by Elder; the other by Vertue. Neither of them is strictly appropriated to any particular book. That in the German edition of his "Wisdom of God in the Creation," published at Leipsic in 1732, appears to be copied from one of these, and yet is so unlike them in expression, that if it were possible, one would suppose it taken from some other portrait of the same person. RAY, in Geography, a town of France, in the department of the Upper Seine; 12 miles E. of Champlite. See Radius.

RAY, in Geometry. See Radius.

RAY, Radius, in Optics, a beam or line of light, propagated from a radiant point, through any medium.

Sir Isaac Newton defines rays to be the least parts of light, whether seen in the same line, or contemporary in several lines.

For, that light consists of parts of both kinds, appears hence, that one may stop what comes this moment in any point, and let pass that which comes the next; and again, one may stop what comes in this point, and let pass that in the next. Now, the least light, or part of light, which may thus stopp'd alone, he calls a ray of light.

A ray of light is, therefore, considered as an infinitely narrow portion, or an evanescent element of a stream of light; and a pencil, as a small detached stream, composed of a collection of such rays accompanying each other. As we cannot exhibit to the senses a single mathematical line, except as the boundary of two surfaces; in the same manner, we cannot exhibit a single ray of light, except as the minute interval between light and darkness, or as the lateral limit of a pencil of light.

If the parts of a ray of light do all lie straight between the radiant and the eye, which is the case when it moves through the same uniform substance or a vacuum, called a medium, the ray is said to be direct: the laws and properties of which make the subject of optics. If any of them be turned out of that direction, or bent in their passage, the ray is said to be refracted: and that branch of optics which treats of these refracted rays, is called dioptrics; which see. See also Refraction.

If it strike on the surface, or medium attached to the surface, of any body, and be driven back, it is said to be reflected: and that branch of optics which treats of these refracted rays, is called catoptrics; which see. See also Reflection.

In each case, the ray, as it falls either directly on the eye, or on the point of reflection, or of refraction, is said to be incident: and the angle which the incident ray makes with the perpendicular to the reflecting surface at the point of incidence, is called the angle of incidence; and the angle which the reflected ray makes with the same perpendicular, is called the angle of reflection; and also, the angle which the refracted ray makes with a perpendicular to the refracting surface produced, is called the angle of refraction.

Again, if several rays be propagated from the radiant equidistantly from one another, they are called parallel rays. If they come inclining towards each other, they are called converging rays. And if they go continually receding from each other, they are called diverging rays.

It is evident that the rays of light, which come from a luminous point, must fall divergingly upon any given surface; yet when the object is very distant, compared with the interval that separates these rays, the divergency of the rays becomes inappreciable; hence the rays of the sun, of the moon, of the stars, &c. are deemed parallel rays. When the luminous point is near, then the rays are sensibly diverging.

It is from the various circumstances of rays, that the several kinds of bodies are distinguished in optics. A body, e.g., that diffuses its own light, or emits rays of its own, is called a luminous body. If it only reflects rays which it receives from another, it is called an illuminated body.

This distinction, however, is not always observed; for a luminous body, in common language, means any visible object, whether it be visible by the emission of original light, like the sun, a candle, &c. or by reflected light, like the moon, or any other celestial or terrestrial object that has no native light, or that does not emit its own light.

If an object only transmits rays, it is called a transparent body. So that transparent bodies, such as water, glass, &c. are those through which light will pass, or through which our eyes can perceive objects situated on the other side, and all such bodies, as also a vacuum, are denominated mediums in optics.

If it intercept the rays, or refuse them passage, so that nothing can be seen through it, it is called an opaque body.

Hence no body radiates, i.e., emits rays, unless it be either luminous, or illuminated.

It is by means of rays reflected from the several points of illuminated objects to the eye, that they become visible, and that vision is performed; whence such rays are called visual rays.

When an eye views any object directly, some of the rays, which proceed from every perceivable point of the object, enter the eye, and the whole number of rays, or quantity of light, which thus enters the eye, is circumjacent by the rays which proceed from the extreme points of the object; and the angle which these extreme rays form at the eye is called the visual angle, from the magnitude of which we principally judge of the distance of a known object. Thus, if the same object is represented at different distances, it is evident that the farther the object is from the eye, the smaller will the visual angle be. Supposing also the distance between the eye and the object to remain the same, if by any means the rays of light are bent so as to enlarge the visual angle, then the object will appear larger, or it is said to be magnified; and on the contrary, if the visual angle be diminished, then the object will appear smaller, in which case it is said to be diminished.

In effect, we find that any point of an object is seen in all places to which a right line may be drawn from that point: but it is allowed, nothing can be seen without light; therefore every point of an object diffuses innumerable rays every way. Again, from other experiments it appears, that the images of all objects, whence right lines may be drawn to
RAYS.

The eye, are painted in the eye, behind the crystalline, very small, but very distinct.

And lastly, from other experiments, that each ray produces an image of the radiant point: and that the several rays emitted from the same point are again united in one point, by the crystalline, and other humours of the eye; and thus thrown on the retina.

It is the fulbility or clofeness of the rays emitted from a luminous body, that constitutes the interfenes of the light. Yet the direction in which the rays strike the eye, has a considerable influence. In effect, a perpendicular ray, striking with more force than an oblique one, in the ratio of the whole line to the line of the angle of obliquity (as follows from the laws of perfection), which in, a perpendicular ray will affect the eye more vividly than an oblique one, in that ratio.

If then the fulbility of the rays be equal, the intensity will he as the direction: if the direction be the fame, the interfenes will be as the fulbility: if both differ, the interfenes will be in a ratio compounded of the direction and the ruphility.

Hence, first, if light be propagated in parallel rays through an unrefiling medium, its intensity will not be varied by dilance.

Secondly, if light be propagated in diverging rays through an unrefiling medium, its intensity will decrease in a duplicate ratio of the distances from the radiant point, reciprocally.

Thirdly, if light be propagated in converging rays through an unrefiling medium; its intensity will increase in a duplicate ratio of the distances from the point of convergence, reciprocally.

Fourthly, if the breadth of an illuminated plane be to the distance of the radiant point as 1 to 2,000,000, it is the fame thing as if the ray struck upon it parallel; and hence, the diameter of the pupil of the eye, when largest, scarcely exceeds 4th or 5th of an inch; the rays will fall upon it parallel as to fente, at the distance of 3860 English feet, which is nearly fix furlongs. See Light.

The effect of concave lefles, and convex mirrors, is to make parallel rays diverge; converging rays become parallel; and diverging rays to become more divergent.

The effect of convex lefles, and concave mirrors, is to make diverging rays become parallel; parallel rays become convergent; and converging rays to converge the more. See LENS.

The rays of light are not homogeneous, or similar, but differ in all the properties with which we are acquainted; viz. refrangibility, refexibility, and colour.

It is probable that from the different refrangibility the other differences have their rife; at least it appears, that those rays which agree or differ in this, do fo in all the rest. Thus, from the different fentifions the differently difperfed rays excite in us, we call them red rays, yellow rays, &c.

The effect of the prisms is to feparate and fort the different kinds of rays, which come blended promifcuously from the fun; and to throw each kind by itself, according to its degree of refrangibility and colour, red to red, blue to blue, &c.

Besides refrangibility, and the other properties of the rays of light already aqcrinted by observation and experiment, Sir Ifaac Newton fuppofed they may have many more: particularly, a power of being inflected, or bent, by the action of diftant bodies; and those rays which differ in refrangibility, he conceives likewife to differ in this flexibility.

In passing by the edges and fides of bodies, he conceives that the rays may be bent feveral times backwards and forwards, with a motion like that of an ed; and that those rays which appear to fall on bodies are reflected or refracted before they arrive at the bodies: and adds, that they may be reftraeted, reflected, and inflicted, all by the fame principle acting in different circumftances. See reflection and LIGHT. See also REFLECTION and REFRACTION.

Again, do not the rays, falling on the bottom of the eye, excite vibrations in the retina, which, being propagated along the fibres of the optic nerve into the brain, cause vision? and do not feveral forts of rays make vibrations of feveral bignefies, which excite fentifions of feveral colours, much after the manner as the vibrations of the air, according to their feveral bignefies, excite fentifions of feveral founds?

Particulars, do not the moft refrangible rays excite the fhorteft vibrations, to make a fentifion of a deep violet; and the lealt refrangible the largeft, to make a fentifion of a deep red? and the feveral intermediate kinds of rays, vibrations of intermediate bignefies, to make fentifions of the intermediate colours?

And may not the harmony and difcord of colours arise from the proportion of these vibrations; as thofe of founct depend on the vibrations of the air; for fome colours, if viewed together, are agreeable, as gold and indigo; others difagreeable. See Colour.

Again, have not the rays of light feveral fides endued with feveral original properties? It is certain we find, that every ray of light has two opposite fides, originally endued with a property, on which the unual refraction of illand cryftal depends, and other two opposite fides endued with that property.

Laffly, are not the rays of light very small bodies emitted from shining fubftances?

Such bodies may have all the conditions of light: and there is that action and re-action between transparent bodies and light, which very much resembles the attractive force between other bodies. Nothing more is required for the production of all the various colours, and all the degrees of refrangibility, but that the rays of light be bodies of different fizes; the leal of which may make violet the weakest and darkest of the colours, and the moft easily diverted by refrating furface from its rectilinear course; and the reft as they are bigger and bigger, may make the stronger and more lucid colours, blue, green, yellow, and red. (See Colour and LIGHT.) Nor is any thing more requisite for the putting of the rays into fits of ealy refefion, and eafy transmission, than that they may be small bodies, which, by attraction, or fome other force, excite vibrations in the bodies they act upon; which vibrations, being fiftier than the rays, overcome them fucceflively, and agitate them fo as by degrees to increase and diminish their velocity, and thereby put them into thofe fits. Laffly, the unual refraction of illand cryftal appears very much as if it were performed by fome attractive virtue lodged in certain fides both of the rays, and of the cryftal.

Rays of Heat denote feparate portions of that emanation, which proceeds from an heated body, when placed in a colder temperature, and which expands itself in every direction, provided it be not prevented by the interpolation of particular fubftances. This appellation is adopted and thus applied, not becaufe that emanation is certainly known to conftitute of feparate beams, but merely for the convenience of explanation. The rays of heat are not the fame with the rays of light. If this were the cafe, a certain quantity of
RAYS.

of heat ought to be accompanied with the same quantity of light: whereas it is found, that several substances emit a considerable quantity of light without any sensible heat, and others give out a considerable portion of heat without any light. But that there are two distinct powers of nature is a proposition, that has been amply illustrated, and most satisfactorily established by the discoveries and experiments of Dr. Herschel. This celebrated astronomer cautions those who peruse the account of his experiments and observations upon them, from concluding, that in using the words rays, he means to oppose, much less to countenance, the opinion of those philosophers, who still believe, that light itself comes to us from the sun, not by rays, but by the supposed vibration of an elastic ether, every where diffused through space; he merely claims the same privilege for the rays that occur in heat, which they do not scruple to allow to those that illuminate objects. For in what manner forever these rays may be effected, he undertakes to prove, that the evidence, either for rays, or for vibrations, which occasion light, stands on the same foundation on which the radiance of the illuminating principle, light, is built.

Proposing to give a comparative view of the operations that may be performed on the rays that occasion heat, and of those which are known to have been effected on the rays that occasion light, he selects such facts as are well known with regard to the latter. Light, he says, both solar and terrestrial, is a refraction occasioned by rays emanating from luminous bodies, which have a power of illuminating objects; and, according to circumstances, of making them to appear of various colours. The rays of light are subject to the laws both of refraction and of reflection; but they are of different refrangibility. They are liable to be stopped in certain proportions, when transmitted through diaphanous bodies; and also to be scattered on rough surfaces. They are also supposed to have a power of heating bodies; but this is a subject "a sub judice." The familiar propositions, which it is his design to prove, and which by a variety of curious and well-conducted experiments he has confirmed, are as follows. Heat, both solar and terrestrial, is a sensation occasioned by rays emanating from luminous substances, which have a power of heating bodies. These rays are subject to the laws of reflection and of refraction; and they are of different refrangibility. They are liable to be stopped in certain proportions, when transmitted through diaphanous bodies; and to be scattered on rough surfaces; and in a certain state of energy, they may be supposed to have a power of illuminating objects, which latter property remains to be examined.

In the examination of the illuminating and heating power of the prismatic colours, our author observes, that the red-making rays are very far from having the same power as the orange; the orange possesses more of it than the red; and the yellow rays illuminate objects still more perfectly. The maximum of illumination lies in the brightest yellow, or palest green. The green itself is nearly equally bright with the yellow; but from the full deep green, the illuminating power decreases very sensibly; that of the blue is nearly upon a par with that of the red; the indigo has much less than the blue; and the violet is very deficient. Our author infers from other experiments, that the heating power of the prismatic colours is very far from being equally distributed; and that the red rays are chiefly eminent in this respect. Allowing that the power of heating is chiefly lodged in the red-making rays, it accounts for the comfortable warmth that is thrown out from a fire, when it is in the state of a red glow, and for the heat which is given by charcoal, coke, and balls of small coal mixed up with clay, used in hot-houses; all which throw out red light. It also explains the reason, why the yellow, green, blue, and purple flames of burning spirits mixed with fuel, occasion so little heat that a hand is not materially injured, when palled through their coruscations.

Having ascertained, that radiant heat is subject not only to the laws of refraction, but to those also of the different refrangibility of light, Dr. Herschel is led to form, that this heat consists of particles of light of a certain range of momenta, which range may extend a little farther, on each side of refrangibility, than that of light. In a gradual exposure of the thermometer to the rays of the prismatic spectrum, beginning from the violet, he found that he arrived at the maximum of light long before he came to that of heat, which lies at the other extreme. By several experiments it appears, that the maximum of illumination has little more than half the heat of the full red rays; and from other experiments our author concludes, that the full red falls still short of the maximum of heat, which perhaps lies even a little beyond visible refraction. In this case, radiant heat will at least partly, if not chiefly, consist, if the expression may be allowed, of invisible light, that is, of rays coming from the sun, that have such a momentum as to be unit for vision. Admitting it as highly probable, that the organs of light are only adapted to receive impressions from particles of a certain momentum, this will explain why the maximum of illumination should be in the middle of the refrangible rays, as those which have greater or less momenta, are likely to become equally unfit for impressions of light. Whereas, in radiant heat, there may be no such limitation to the momentum of its particles.

From the powerful effects of a burning lens, however, we derive information, that the momentum of terrestrial radiant heat is not likely to exceed that of the sun; and, consequently, the refrangibility of solar rays cannot extend much beyond that of solar solar rays. Hence, we may also infer, that the invisible heat of red-hot iron, gradually cooled till it ceases to shine, has the momentum of the invisible rays, which, in the solar spectrum viewed by daylight, go to the confines of red, and this will afford an easy solution of the reflection of invisible heat by concave mirrors.

Our author deduces from various experiments with the thermometer abundant evidence, that there are rays coming from the sun, which are less refrangible than any of those that affect the light. They are invested with a high power of heating bodies, but with none of the power of illuminating objects; and on this account they have hitherto escaped notice. At the distance of fifty-two inches from the prism, there was still a considerable heating power exerted by the invisible rays, an inch and a half beyond the red ones, measured upon their projection on a horizontal plane. Moreover, the power of heating is extended to the utmost limits of the visible violet rays, but not beyond them; and it is gradually impaired, as the rays become more refrangible. The maximum of the heating power is found to be vested among the invisible rays, and it is probably not less than half an inch beyond the last visible ones. It is also shewn, that the sun's invisible rays, in their least refrangible state, and considerably beyond the maximum, still exert a heating power fully equal to that of red-coloured light; and consequently, if we may infer the quantity of the efficient from the effect produced, the invisible rays of the sun probably far exceed the visible ones in number. The general conclusion with which Dr. Herschel closes his account of one series of
of experiments and his reasoning upon them, is in the following manner: "If," says he, "we call light those rays which illuminate objects, and radiant heat, those which heat bodies, it may be inquired whether light be essentially different from radiant heat?" In answer to which I would suggest, that we are not allowed by the rules of philosophy to admit two different causes to explain certain effects, if they may be accounted for by one. A beam of radiant heat emanating from the sun, consists of rays that are differently refrangible. The range of their extent, when dispersed by a prism, begins at violet-coloured light, where they are most refracted, and have the least efficacy. We have traced these calorific rays throughout the whole extent of the prismatic spectrum, and found their power increasing, while their refrangibility was lessened, as far as to the confines of red coloured light. But their diminishing refrangibility, and increasing power, did not stop here; for we have pursued them a considerable way beyond the prismatic spectrum into an invisible state, till exerting their increasing energy, with a decrease of refrangibility up to the maximum of their power; and have also traced them to that state, where, though still less refracted, their energy, on account, we may suppose, of their now falling density, decreased pretty fast; after which the invisible thermometrical spectrum, if I may so call it, soon vanished."

"If this," continues our author, "be a true account of solar heat, and of the support of which I appeal to my experiments, it remains only for us to admit, that such of the rays of the sun as have the refrangibility of those which are contained in the prismatic spectrum, by the contraction of the organs of light, are admitted, under the appearance of light and colour; and that the red, being stopped in the coats and humours of the eye, act upon them, as they are known to do upon all other parts of our body, by occasioning a sensation of heat."

Although, as we have above stated, the rays of light and those of heat, possess many similar properties, yet Dr. Herchel has shewn, that there are some striking and subliminal differences between them. The rays of heat are of a much more extensive refrangibility than those of light, as our author has clearly and ineptly demonstrated both by reasoning and experiment: nor do those rays agree either in their mean refrangibility, nor in the situation of their maxima. Where we have most light, there is but little heat, and where we have most heat, we find no light at all. (See Refrangibility.) It is found, that the lines of refraction of the heat-making rays are in a constant ratio to the lines of incidence; but that the focus of the rays of heat in burning glasses is different from the focus of the rays of light: that of heat being farther removed from the lens than the focus of light, probably not less than a quarter of an inch: the heat at half an inch beyond the focus of light becoming ill equal to that in the focus. Although light and heat are both refrangible, the ratio of the lines of incidence and refraction of the mean rays is not the same in both. Heat is evidently less refrangible than light. From experiments relating to the transmission of light and heat through diaphanous bodies it appears, that no kind of regularity takes place in the proportion of rays of one sort and of another, which are flopped in their passage. Heat and light seem to be entirely unconnected, and the rays that occasion them are different. We have several tables, formed from the author's experiments, and shewing the quantities of light and heat intercepted by different substances. The blue-white and dull-glasses, e.g. stop nearly three times as much heat as light, whereas the greenish crown glasses stop only about one-fourth more of the former than of the latter.

From a table exhibiting the effects of coloured glasses, it appears, that a yellow glass stops only 333 rays of heat, but stops 819 of light; on the contrary, a pale blue stops 812 rays of heat, and but 634 of light. Again, a dark blue glass stops only 362 rays of heat, but intercepts 801 of light; and a dark red glass stops no more than 606 rays of heat, and yet intercepts nearly all the light, scarcely one ray out of 5000 being able to make its way through it. For the conclusions deduced from these tables, as they evidence the non-identity of the rays of heat and those of light, and for the tables themselves, we must refer to the author's own paper, ubi infra. We are restrained by our limits from pursuing this curious subject, and from entering on a detail of Dr. Herchel's experiments, illustrating and confirming principles, the discovery of which must be allowed to be one of the greatest that has been made since the days of Newton, although the theories of some speculative philosophers might have led to it a few years earlier. Dr. Herchel was occupied in determining the properties of various kinds of coloured glasses, which rendered them more or less fit for enabling the eye to view the sun through a telescope; and for this purpose it was necessary to inquire which of the rays would furnish the greatest quantity of light, without subjecting the eye to the inconvenience of uncomfortable heat. He first observed that the heat became more and more considerable as the thermometer approached the extreme red rays in the prismatic spectrum; and pursuing the experiment, he found not only that the heat continued, beyond the visible spectrum, but that it was even more intense where the thermometer was at a little distance in the limits of the spectrum, than in any point within it; as we have already stated. For Dr. Herchel's communications to the Royal Society on this subject, we refer to the 49th volume of the Philosophical Transactions for the year 1800, part ii. p. 255, &c. p. 284, &c. p. 293, &c. part iii. p. 437, &c.

Sir Henry Englefield has repeated Dr. Herchel's experiments with many precautions, and Mr. (Sir H.) Davy was a witness of their perfect accuracy. The excess of heat beyond the spectrum was even considerable enough to be ascertained by the sense of warmth occasioned by shewing it on the hand.

It was first observed in Germany by Ritter, and soon afterwards in England by Dr. Wolffson; that the nitrate of silver is blackened by invisible rays, which extend beyond the prismatic spectrum, on the violet side. It is therefore probable, that those black or invisible rays, the violet, blue, green, perhaps the yellow, and the red rays of light, and the rays of invisible heat, constitute seven different degrees of the same scale, distinguished from each other into this limited number, not by natural divisions, but by their effects on our senses; and we may also conclude that there is some familiar relation between heated and luminous bodies of different kinds. See Young's Phil. Lect. vol. i. p. 539. See Heat and Refraction.

M. Delaroche has found, that the rays of invisible heat traverse glasses with difficulty at a temperature below that of boiling water; but that they traverse it with a facility, always increasing with the temperature, as it approaches the point when bodies become luminous, and from these experiments it would appear, that the modification, whatever it be, which must be imposed upon the invisible rays to render them more and more capable of passing through glasses, makes them approach more and more to the state in which they must be when they penetrate our eyes, and occasion the sensation of vision. The same ingenious philosopher has likewise found, that the rays of heat which have passed through
through a plate of glass are proportionably more adapted to pass through a second plate; and from this circumstance we deduce a new proof of the peculiar state of these rays, and of the modification which they acquire. Mellels. Gay-Lussac and Thenard have proved that all the changes of colour produced by light may be imitated and produced by heat, and by an elevation of temperature not exceeding 212°. Other phenomena previously observed indicated, that in the comparison of the actions of heat and light in heating bodies, or producing chemical changes in them, there is a great difference in the rays of different colours. M. Rochon announced the fact amply confirmed by Dr. Herschel, that the heat produced by the different rays of the prismatic spectrum was unequal. As Dr. Herschel fixed the maximum effect beyond the red rays, and, as we have already stated, that the most heating rays of the spectrum were entirely, or nearly, invisible; Dr. Wollaston, and Mellels. Ritter and Beckmann, having examined the opposite, or violet end of the spectrum, found that this likewise poffefled peculiar properties, and that, beyond the violet, there are invisible rays, which pencil, in greatest perfection, the power of determining chemical combinations. It has been a subject of interesting research, whether the invisible, or almost invisible rays, situated beyond the extremities of the spectrum, poffefs any other properties of light. *E. gr. If the reflection of them from polished glass can give them that modification which Malus has distinguished by the name of “polarization.”* (See Light.) M. Berthollet engaged Mellels. Malus and Berard to undertake this double object. M. Malus’s death prevented his prosecution of the subject; but what he began M. Berard accomplished with the utmost possible exactness. By means of the heliotrope, which Malus caufed to be contructed for the philosophical cabinet of M. Berthollet, he obtained a ray of light, perfectly fixed, on which he could make experiments at pleasure. By decomposing this ray with a prism, he obtained an immovable coloured spectrum; and by placing very finelv thermometers in the spaces occupied by the different colours, he was enabled to compare their calorific effects with the utmost certainty. He also ascertained their chemical properties by substituting, in place of the thermometers, chemical compounds easily altered. He first of all observed the calorific power of the different rays, which, it is known, are in this respect unequal. M. Rochon, who is said to have first observed this inequality, placed the maximum of heat in the yellow ray, where the illuminating power is the greatest. Dr. Herschel, as we have before shewn, placed it out of the spectrum, and beyond the red ray. The experiments of Herschel have been confirmed by those of Berard, as far as they respect the progreffive heating power of the rays from the violet to the red; but he found the greatest heating power at the extremity of the spectrum itself, and not beyond it. He fixed it at the point, where the bulb of the thermometer was still entirely covered with the red ray; and he found that the thermometer sunk progressively, in proportion as the distance of its bulb from the red ray increased. When he placed the thermometer quite beyond the visible spectrum, on the spot where Herschel fixed the maximum of heat, its elevation above that of the ambient air was only one-fifth of what it had been in the red ray itself. The absolute intensity of the heat produced was likewise less in the experiments of Berard than in those of Herschel.

M. Berard wished to know if these properties would exist in each of the pencils into which the ray divides itself in passing through a rhomboïd of Iceland flar. In this case each of the two spectra exhibited the fame properties. In both, the calorific power diminished from the violet to the red end; and it existed beyond the last visible red rays. In this operation the luminous molecules are polarized by the crystal. In order to determine whether the invisible rays of heat experience the fame effect, M. Berard received the solar ray upon a polished and transparent glass, which polarized a portion of it by reflection. This reflected ray was then received upon a second glass, fixed in an apparatus, which permitted it to be turned round the ray under a constant incidence, and this incidence itself was determined in such a manner, that in a certain position of the glass the reflection ceased to take place. We know, from the experiments of Malus, that a glass may be always disposed in such a manner that this condition is fulfilled. Things being thus disposed, by collecting with a mirror the calorific and luminous rays reflected from the second glass, and directing them upon a thermometer, M. Berard found, that as long as light was reflected the thermometer was elevated, and of course the heat was reflected likewise; but when, from the position of the second glass, the light was totally transmitted, the heat was transmitted at the same time, and the thermometer was not elevated. In this experiment, then, as well as the preceding, the calorific principle, whatever it may be, never separates from the luminous molecules.

To the ray of solar light employed in this experiment, M. Berard substituted a pencil of radiant heat proceeding from a body hot, but not red, and even not luminous. The effect was the same as before. The thermometer rose when the second glass was so situated as to reflect light, and it did not rise when the second could not reflect light. Therefore the particles of invisible radiant heat are modified by reflection, precisely like light.

After having fluided the calorific properties of the different rays of the spectrum, M. Berard examined their chemical properties. When muriate of silver, or other white salts of silver, are exposed to light, they become dark coloured very speedily. Guinard thus exposed to light pails from yellow to green, as Dr. Wollaston observed. Gay-Lussac and Thenard discovered another action of this light still more prompt and energetic. When a mixture of oxyacetic acid gas and hydrogen gas are exposed to the action of solar light, a detonation takes place, and water and muriate acido are formed. These different phenomena enabled M. Berard to examine the chemical powers of the different rays of the spectrum. By exposing to the different coloured rays, pieces of card impregnated with muriate of silver, or small phials filled with the detonating mixture, he was enabled to judge of the energy of each by the intensity or rapidity of the chemical change which it produced. He found that the chemical intensity was greatest at the violet end of the spectrum, and that it extended, as Ritter and Wollaston had observed, a little beyond that extremity. When he left substances exposed for a certain time to the action of each ray, he observed sensible effects, though with an intensity continually decreasing in the indigo and blue rays. Hence we must consider it as extremely probable, that if he had been able to employ re-actives still more sensible, he would have observed analogous effects, but still more sensible, even in the other rays. To shew clearly the great disproportion which exists in this respect between the energies of the different rays, M. Berard concentrated, by means of a lens, all that part of the spectrum which extends from the green to the extreme violet; and he concentrated, by means of another lens, all that portion which extends from the green to the extremity of the red. This last pencil formed a white point so brilliant that the eyes were scarcely able to endure it; yet the muriate of silver remained more than two hours exposed to this brilliant light without undergoing any sensi-

ble
RAY

ble alteration. On the other hand, when exposed to the other pencil, which was much less bright, and less hot, it was blackened in less than six minutes. M. Berard concluded, from this experiment, that the chemical effects produced by light are not solely owing to the heat developed in the body by its combining with the substance of the body; because, on such a supposition, the faculty of producing chemical combinations ought to be greatest in those rays which possess the faculty of heating in the greatest perfection; but perhaps we should find less opposition between these two opinions, if we attended to the different results which may be produced by the same agent placed in different circumstances, and if we considered that agents of a nature quite dissimilar may determine the same combinations when they are employed.

Various hypotheses have been suggested in order to account for the properties above stated. If we wish to consider solar light as composed of three distinct substances, one of which occasions light, another heat, and the third chemical combinations; it will follow that each of these substances is separable by the prism into an infinity of different modifications, like light itself; since we find, by experiment, that each of the three properties, chemical, colorific, and caloric, is spread, though unequally, over a certain extent of the spectrum. Hence we must suppose, on this hypothesis, that there exist three spectrums one above another; namely, a colorific, a calorific, and a chemical spectrum. We must, likewise, admit that each of the substances which compose these spectrums, and even each molecule of unequal refrangibility which constitutes these substances, is endowed, like the molecules of visible light, with the property of being polarized by reflection, and of escaping from reflection in the same positions as the luminous molecules, &c.

In view of this complication of ideas, let us conceive simply, according to the phenomena, that light is composed of a collection of rays unequally refrangible, and of course unequally attracted by bodies. This supposes original differences in their size and velocity, or in their affinities. Why should those rays, which differ already in so many things, produce upon thermometers, or upon our organs, the same sensations of heat or light? Why should they have the same energy to form or separate combinations? Would it not be quite natural that vision should not operate on our eyes, except within certain limits of refrangibility; and that too little or too much refrangibility should render it equally incapable of producing that effect? Perhaps these rays may be visible to other eyes than ours, perhaps they are fo to certain animals, which would account for certain actions that appear to us marvellous. In a word, we may conceive the colorific and chemical faculty to vary through the whole length of the spectrum, at the same time with the refrangibility, but according to different functions; so that the calorific faculty is at its minimum at the violet end of the spectrum, and at its maximum at the red end; while, on the other hand, the chemical faculty expressed by another function is at its minimum at the red end, and at its maximum at the violet end, or a little beyond it. This simple supposition, which is only the simple statement of the phenomena, equally agrees with all the facts hitherto observed, and accounts for these established by M. Berard, and even enables us to predict them. In fact, if all the rays, which produce the three orders of phenomena, are rays of light, they must of course be polarized in passing through Iceland crystal, or in being reflected from a polished glass with a determined incidence; and when they have received these modifications, they must be reflected by another glass, if it is properly placed, to exert its reflecting energy on the luminous molecules. On the other hand, if that force is null on the visible luminous molecules, the invisible light will not be any longer reflected for the cause which occasions or prevents reflection appears to act equally upon all the molecules, whatever their refrangibility may be. It ought, therefore, to act upon the molecules of invisible light, the condition of visibility or invisibility relating merely to our eyes, and not to the nature of the molecules which produce these sensations in us.

This mode of viewing the facts appeared to Meffrs. Berthollet, Chaptal, and Biot, who made a report to the Institute on the Memoire of Berard, the most natural and simple; though the model referre of Berard restrained him from deciding in a case, not sufficiently examined by the test of experiment. Annal. de Chimie, vol. XXXV. p. 399. or Thomson's Annals of Philosophy, No. 9.

RAY, Common, in Optics, is sometimes used for a right line drawn from the point of concourse of the two optical axes, through the middle of the right line which passes through the middle of the centres of the pupils of the two eyes.

RAY, Cone of. See Cone.
RAY, Diffraction of. See Diffraction.
RAY, Inclination of incident. See Inclination.
RAY, Optic. See Optic.
RAY, Polarization of. See Polarization.
RAY, Pyramidal of. See Optic Pyramids.
RAY of Curvature, in Geometry, is used to signify the semi-circle of the curve of curvature. See Radius and Curvature.

RAY, Raia, in Ichthyology. See Raia.
RAY, Clavated. See Raia Clavata, and Thorback.
RAY, Eagle. See Raia Aquila.
RAY, Electric or Smooth, a species of ray. See Raia, Torpedo, and Anatomy of Fish.
RAY, Fuller, Raia fulcna, a species of ray, deriving its name from the instrument which fullers use in smoothing cloth, the back being rough and spiny. See Raia Fulcna.

RAY, Oblong. See Raia and Rhinobatos.
RAY, Ocellated. See Raia and Miraletus.
RAY, Rough. See Raia Rubus. At Scarborough, where it is common, it is called the white huss or gillet.
RAY, Shagreen, called at Scarborough the French ray, is about the size of the flake, but narrower in its form than the common kinds. The upper part of the body is covered closely with small fragrant-like tubercles, resembling the skin of the dog-fish; and from the vole to the beginning of the pectoral fins is a tuberculated space. Pennant.
RAY, Sharp-nosed. See Raia Oxynochus. This fish makes a snorting noise, and is supposed to be the bos of the ancients, which Oppian describes as the broadest among fishes, and fond of human flesh; adding, that the method it takes of despatching men is by over-laying and keeping them down by its vail weight till they are drowned. Pennant.
RAY, Squin. See Raia Pajlinaca, and Fastinaca Marina.
RAY, in our Old Writers, a word appropriate to cloth never coloured, or dyed, 11 Hen. IV. c. 6. Blount, Cowel.
RAY, in Botany, the spreading marginal florets of a compound flower; see RAYUS. The same term is applied to the sub-divisions of an umbel, more properly denominated
Its general and partial flaks; unless we, like Linnaeus, consider the whole umbel as one aggregate flower. See Umbella, and Inflorescence.

Ray-graffs, in Agriculture, an useful sort of early grafs that has long been, and will be, much cultivated by the farmer in some districts. There are said to be different varieties of this grafs, but that grown by Mr. Peacey, of Devonshire, has been found, on experience, much superior to the common fort. This grafs has sometimes the title of rye-graffs. See Lolium Perenne.

It has been remarked by the Rev. Mr. Duncan, of Kilmarnock, in the fourth volume of Communications to the Board of Agriculture, that it has been found of late that there is an annual and perennial kind; that the latter should only be fown; but that the annual feed, he thinks, affords the greatest and most palatable crop of hay, and may be sown on those light soils which more readily tend to grafs, at least a considerable proportion of it should be blended with the perennial feed. He adds, that the two kinds of feeds are readily distinghuished by a careful observer, as the perennial is smaller, and fairer in colour, than the annual, and likewise much lighter. Good annual feed weighs from 21 to 24 lbs. avoirdupois weight per buflie, but the perennial only from 16 to 18 lbs. As no distinction of these forts was formerly made by farmers, he suggests it as probable that they have come to be known and distinghuished, from the circumstance of no ray-graffs disappoeing wholly the first year, by which some persons have been tempted, from the high price of the feed, to allow what remained in the second year to advance to maturity, though to the great injury of the pasture. It is therefore from the feed of the second year's crop that he supposes the perennial grafs has gradually originated; and its inferiority in point of substance seems, he thinks, to prove the supposition. By this means the farmer may, by allotting a small portion of good land for the purpofe, fupply himself with what is faid to be the perennial feed, without submitting to the impofition of an extravagant price, and may probably endure or improve upon the durability of it, by collecting feed from the third or fourth year's growth.

It is found to be an excellent grafs for paffure as well as hay. It has an early, but not very abundant, foliage. It is highly relifhed by cattle and sheep. From its being apt to run up into flowering ftems, it should be kept well fed down. From its secreting and depositing much facetarine matter in the joints of the ftems, it affords a large proportion of nutritive matter for the support of animals, both in its green state and when made into hay. And it is faid not to affect the wind of horses, which renders it particularly valuable for hunting and racing horses.

It has, however, been objected to by fome, from the quantity of flower ftems which it fends up; but this is afferted by others to be only the cafe when it grows in dry upland situations. It is found, of course, to vary much under different circumftances and situations.

The fows that are most fuitable for it are thofe of the loamy and sandy kinds, but it is capable of being grown on thofe of the clayey forts when not too fiff. On the two fiff forts, a mixture with other grafses, it frequently becomes permanent, and affords an ufeful spring food, efpecialy for sheep Rock.

As it is found to produce a thick well-connected fward in fows of the rich fertile kinds, it has been suppofed only fuitable to them, though occasionally met with in thofe of the poorer descriptions.

In England it is found very bad for the strong wet heavy lands. But in other districts it is most fown in fift clayey fows, where clover is liable to fail in coming up well. Some, however, find that a light fior is quite as fuitable for it as one of a clayey nature; and that though it may be most fown in fift heavy lands, it is not from the notion that lighter fows are fels suited to it, but that such lands may be covered with this grafs, should the clover crop not turn out well in confequence of the great ftiffnefs of thofe clayey fows.

On the eift clayey fows the proportion of feed is ufually from one buflie to one buflie and a half of ray-graffs, with eight or ten pounds of red clover feed, to the acre. On other fows from fix to ten gallows of ray-graffs, with from five to eight pounds of red clover feed, and from two to four pounds of trefoil feed, are used to the acre; some adding to thefe, two, three, or more, pounds of white clover feed.

In Suffolk, for a layer for one or two years, they employ of ray-graffs feed three gallows, and of red clover and trefoil feed each one gallon, to the acre.

But for permanent paffure the proportion is this. Of ray-graffs feed four gallows, Dutch clover and trefoil feed, of each two gallows to the acre. Other different proportions are made use of in different cafes.

It has been well remarked by Dr. Campbell, in the third volume of Communications to the Board of Agriculture, that when land is in a proper state of manure, ray-graffs united with white clover, will form a perfeft fward the latter end of the second year after it is fown. A particular field, of about five acres, that was fown with these two grafses only, was, he fays, more perfectly graffed over, than others, which had the addition of trefoil and rib-graffs, and which were fown at the fame time. A neighbour of his, the only man in the county that had tried ray-graffs, told him it would not ansver, and referred him to a particular field where fome had been fown. The faft was, the doctof fays, that he had cropped his field with oats until it was no longer worth ploughing, and then, with his laft feed, he fowed ray-graffs, which certainly did not flourifh. But his argument would, he thinks, have been equally conclusive againft any grafs or grain whatever. The ray-graffs languifhed, and finally died away, giving place to the vegetaftion fuitable to the state of the land. If it be expected that ray-graffs, or any other good grafses, should thrive and produce abundant crops on exhausted or poor land, it must not, he fays, be in the foil which occurs here. And he adds the following ufeful remarks, on converting ray-graffs into hay; it is neceffary to cut it at a period previous to its being too ripe as to have perfed its feed, and changed to a yellow colour; for in this cafe a great part of the juices of the plant, which confitute a principal part of the nutriment it is to afford, will be converted into a species of straw, and its nutritive properties be proportionally diminished. When it is made into hay, perfons not acquainted with its qualities are apt to objef to its apparent coafenefs, which proceeds from its confronting almost entirely of flowering-ftems, the ray-graffs having a comparatively smaller proportion of leaves than any other grafses. Whether this be a defect or a merit will, he thinks, depend upon a folution of this queftion: Do the ftems and flowering parts of grafses, or the leaves taken weight for weight, contain the greater proportion of nutriment? It does not appear, he fays, that this has been determined by experiments inlinitated for the purpofe; but it seems probable, from the ftems being so much fweeter than the leaves, (which is particularly perceptible upon chewing them when about half dry,) and from thofe vegeftables which contain much facetarine matter being particularly nutrituous, that the greater proportionate quantity of
nutriment will be found to reside in the stalks; and if so, the advantages of ray-grafts will be decisive. But, however this may be, it is certain that, supposing wet weather comes on during the process of hay-making, the first part of the grafs that decays is the leaf, which soon becomes yellow, and then black, losing all pretensions to nutritive properties; in which case it is evident that almost the whole nutriment contained in the hay, not refined, exclusively, in the flowering-stalks. Ray-grafts then have, in unfavourable hay-weather, an advantage, he thinks, over all others, insomuch as from having fewer leaves it is not so apt to be injured by a continual rain; and it is, besides, when in the cocks, more accessible to the air and wind from lying more open and light; and consequently not so apt to heat and mould as other grafs in similar situations and feasons. And he concludes that it certainly poiffedes the following valuable properties. 1. That there are few grafs so early in the spring. 2. That there are none better relished by cattle, or more nutritive. 3. That it has the power of relieving the effects of bad weather, in ticklish feasons, in a greater degree than other grafs. 4. That there is a greater facility in collecting its feed than of any other grafs.

It is supposed that the prejudices against it have proceeded, 1. From its having been fown in land not capable of producing a full crop of any good vegetable. 2. From allowing it to shoot up so far, as to have formed the feed in the flowering-stalk, before cattle have been turned into paffure, or that it has been cut for hay. Ray-grafts appears, he thinks, to partake more of the nature of grain than any other grafs. Hence, when it has perfected its feed, it shoots out no more stalks, and but few leaves that fean, as lord Kames has juftly observed. Hence it is neceffary to turn cattle into a field of this grafs early in the spring, and to keep it well under by a fufficient quantity of fock; in which cafe it will continue to put out fresh flowering-stalks and leaves during the whole feafon. 3. The hay, for the reafon just alluded, should be cut before it becomes a mere fraw. Common hay-grafts, being compofed of grafs in various fages of growth and ripeness, admits of greater latitude than a field of ray-grafts, becaufe many of them will generally be in a proper flate for cutting, although others may have palled their prime.

He adds the following facts in fupport of its nutritive properties. No hay, says he, could be better relished by my horfes than this was; not a particlf of it was walked by them, or left in the rack; no animals could thrive, coat, or do their work better, than they did, whilst they had this ray-grafts hay to take to. Never was there a greater contraint than when they were put to the natural hay-grafts of the country, after they had finished the other. They were literally starved into the eating of it; and in spite of an additional quantity of corn, they fell away (agreeable to his farming man's mode of exprifion) a kind a-piece. This year nothing can look better than his horfes do upon this hay, (with which some red clover is mixed,) and this, with the addition of very little corn, and that mostly light, the tailings of oats and barley.

These facts place the utility of this grafs in a very striking point of view. And the following, given by Mr. Duncan, are of the fame tendency, as he found in a comparative experiment of pieces of ground laid to paffure with it, and meadow loft-grafts alone and in mixture, that the ray-grafts portion was not only more early ready for the feythe by nearly three weeks, but the hay of it always more greedily eaten by the horfes and cattle, as well as the paffure in flowering years, on the ray-grafts division, constantly eaten bare before the cattle flock would touch that of the fott grafs.

In the county of Essex the farmers in many places have, however, a very indifferent opinion of ray-grafts, believing it to do great injury to the land, especially when of the better kind. When fown with red clover, it does not do so well or is so good as a preparation for wheat, but it anwers well for peafe. In trying it mixed and uninfed with clover, some have found that when without it, it is all the better for the wheat; and that the wire-worm after ray is sure to destroy the wheat.

In weaning calves it is found extremely useful and advantageous, as it agrees very well with them, far better than tares, which are liable to run through them, or fecour.

In Suffolk this grafs is employed in mixture with others, as a sheep-feed, with great benefit and success. The farmers in the tillage parts of Oxfordshire also consider ray-grafts as preparing badly for wheat; they conceive that the wheat which follows will never be found so good where it is found as where there is none. It is thought far from having any ameliorating effects on the land, as it draws water too much. It is never fown alone by fome. It makes the very worst hay, unless cut at an early period, or very young, in the opinion of many.

In Berkshire this grafs is fown in the chalk district, and found to a certainty less nutritious than many other grafs, as well as more exhausting in its nature. When intended for permanent paffure, it is found, in general, to fail in a very few years; and, unless the feed is changed, it will degenerate under any mode of management. It, however, possesses the advantage of being cheap, and of producing early feed, which are objects of no inconsiderable importance on a farm. Some find that the Peacey variety furnithes feed a fortnight or three weeks sooner than the common fort. It is seldom fown fingly, but in mixture with many other artificial grafs, in proportions to fuit the difference of foil. In fome places it is fown with different other artificial grafs in variety, every four years, on different parts of the land, fo as to prevent it getting fick of the fame kind of feeds.

In the intention of hay, it should be cut early, or its juices will be much exhausted. Horfes fed on this fort of hay are found to prefer their wind better than on any other grafs.

In Cheshire the dairy farmers do not consider it a good grafs for producing milk, on which account it is not so much cultivated; its earlhyness, however, has made it esteemed by many; as on almost any soil, fome fuppofe it will be a paffure a week or ten days fooner than any other kind. And its having the property of correcting the tendency of clover to produce flatulence, renders it also highly worthy of the farmer's attention.

When for hay, if not cut early, the produce is scarcely to nutritious as fraw.

This grafs-feed is sometimes fown alone, and the quantity of feeds which the plants afford, and the facility of co[...]

RAYMOND DE PEGNAFORT, in Biography, a fain in the Roman calendar, was a Spaniard by nation, and born at the castle of PegnaFort, in Catalonia, in the year 1175. He received the early part of his education at Barcelona, from whence he removed to the university of Bologna, where he studied the law, took his degrees, and afterwards taught the canon law for some time with great reputation. He was afterwards called to Barcelona, by Berenger, bishop of that city, who made him his canon, and provost of his cathedral church. He held these offices in the year 1218, when he established an institution which led the way to the foundation of the Order of Mercy, (see that article.) In 1222 he resigned his dignities, and became a member of the Dominican order of preaching friars at Barcelona. In 1230, pope Gregory IX. sent for him to Rome, appointed him his chaplain and confessor, and devolved on him the care of preparing on the compilation of the "Decretals." The pontiff would willingly have recompensed him for his labours by presenting him with very considerable church preferment, but he chose rather the quiet of a monastery to the honours and emoluments of the richest fees in Spain and Portugal, which were offered to him. In 1238 he was called to assume the poll of general of his order; but upon the plea of his infirmities, he was suffered, in about two years, to return to his monastery, where he spent the remainder of his long life. He died in 1275, having entered on the 100th year of his age. His overruling dispence, he is said to have been principally instrumental in introducing the Inquisition in the kingdom of Arragon, and into Languedoc, a circumstance which probably was the means of his canonization in the year 1601. He was author of "Summa de Calibus poenito-

RAYMOND, in Geography, a township of America, in Rockingham county, New Hampshire, incorporated in 1764, containing 876 inhabitants; 12 or 14 miles W. of Exeter.

RAYMOND, or Raymond-town, a post-town in Cumberland county, and district of Maine, containing 825 inhabitants; 142 miles N.N.E. of Boston. The land is generally level, excepting one large hill, called Rattlesnake-hill, from its abounding with those reptiles. The greater part of the growth is pine and white oak, and the soil is difficult of culture.

RAYNAL, William-Francis, in Biography, a French writer of celebrity, was born at St. Genies, in the Rouergue, in 1713. He entered at a very early age among the Jesuits, and by his abilities excited high expectations of his future celebrity. His disfavour refrained him to quit the society in the year 1748, although he had made his profession, and had been ordained priest. He now entered his career of authorship, and distinguished himself as a political, historical, and miscellaneous writer. His first piece, published the same year in which he quitted the society, was entitled "Histoire du Stadthouderat;" he next published "Histoire du Parlement d'Angleterre," which gained him much reputation, though it had little claim to the dignified title of history, and was, moreover, tinged with many prejudices, religious and political. He also composed "Anecdotes Literaires," in three vols. 12mo.; and "Memoires de Niron de l'Enclos," and was much employed in the "Merce

The great work of the abbé Raynal was entitled "Histoire Philosphique et Politique des Etablissements et du Commerce des Européens dans les deux Indes," to the composition of which he was led by his engaging in some commercial speculations, thinking them likely to turn out more profitably than literary pursuits. His history was published in 1770, and as it contained history, description, and calculation, intermixed with political and philosophical reflections, and was, through the whole, animated by an ardent spirit of philanthropy and hatred of tyranny, civil and religious, it became popular, and the author was looked up to as one of the reformers of the age. Critics, however, soon found that, as a literary and philosophical work, it would not bear the test of examination. The style, though rich, was exceedingly declamatory; the images were frequently inlaid; and his principles vitiated by the licentiousness of his country; and the facts upon which the whole was founded were derived from incorrect or dubious documents. The author, it should seem, was soon made sensible of the imperfections of his work, and determined to improve it by travel; with this view he visited the principal commercial towns in France, and passed into England and Holland, at every place making inquiries among travellers and merchants with the most unremitting industriousness. On his return, he published at Geneva an improved edition of his work, in 10 vols. 8vo., containing many additions and corrections. Its tone was unaltered, and its attacks upon existing authorities were so bold, that the parliament of Paris ordered it to be burnt, and inflicted a decree for apprehending the author. He retired to Spa, whence he travelled through Germany, and after having visited all the principal places, he returned to France, and lived some time quietly in the southern provinces. At the academies of Marfilles and Lyons he founded several prizes for essays on given subjects, of which the most remarkalbe was whether the discovery of America had been more useful or prejudicial to Europe.

America has now, owing to the quarrel and war subsisting between Great Britain and its colonies, become an object of peculiar interest; and the abbé Raynal, in 1781, published "Tableau et Revolution des Colonies Angloises dans l'Amerique Septentrionale," which was commented upon and exposted by Thomas Paine, who was a zealous and able defender of the American cause, against the mother country.

The abbé came to Paris in the important year 1788, when the revolution was just ready to burst forth. He had not been long in the city, before the National Assembly was convoked, and one of its early acts annulled the decree passed against him; for this favour, he addressed a letter of thanks to the president, containing a retraction of certain principles contained in his work. Observing, afterwards, that the constituent assembly were occupied in decrees which he thought were violent infringements on the rights of property, and in others calculated to augment the popular effervescence, he wrote, in May 1791, a long letter of advice and remonstrance. It was soon seen that the sentiments in this letter were very different from those which were generally expected from the author of the "Histoire Philo-

RAYNERIUS, a learned Italian monk, who flourished most probably in the 13th century, was a native of Pisa. He
He acquired the character of a consummate divine and civilian, and was appointed professor of divinity, as well as raised to the most considerable offices of trust and honour belonging to his order. It is uncertain at what period he died. He left behind him many works, of which the chief is entitled "Pantheologia, etc., Summa universalis Theologia." This is a dictionary of theology, with the subjects disposed of in alphabetical order; it has been held in high estimation among the members of the Catholic communion. It has gone through several editions in folio and quarto. The last edition was printed at Paris in 1655, in 3 vols. folio, with additions of father Nicolai.

RAYNHAM, in Geography, a township of Massachusetts, in Bristol county, taken from Taunton, and incorporated in 1731. It contains 1154 inhabitants. Besides the great river Taunton, this township is watered by several streams, upon which are fixed saw-mills, three grist-mills, a furnace, a forge, and fulling-mill. Here are also numerous ponds, of which Nippennyquit, or Nippanoist, is two miles long and one broad. In this pond millions of alewives annually return and leave their spawn in it. An excellent kind of eel, and various kinds of fish, are found in this township. Besides the usual occupations of husbandry and mechanics, many of the inhabitants are employed in the manufactories of bar-iron, hollow ware, nails, iron for vessels, iron-hovels, potash, thingles, &c. The first forge set up in America was introduced into this town by James and Henry Leonard, natives of England, in 1652. The same family, in the 6th generation, now possesse. King Philip's hunting house flood on the northern side of Fowling pond, about one mile and a quarter from the pond. When the war broke out in 1675, which terminated in the death of the king and the ruin of his tribe, he left strict orders to all his Indians not to hurt the Leonards. Before Philip's time, Fowling pond was two miles long, and three miles and a quarter wide. But the water is now almost gone, and the large tract it once covered is grown up to a thick-fret swamp of cedar and pine. The vicinage has abounded with excellent ore, which has supplied the forge for 80 years; it is, however, incapable of being wrought into iron of the best quality.

RAYNOLDS, or RAINEY, John, in Biography, a learned English divine, was born at Pinhoe, near Exeter, in the year 1549. In 1562 he was admitted a student at Merton college, Oxford, whence he was removed, in 1563, to a fellowship of Corpus Christi college. In 1572, having taken his degrees in the arts, he was appointed Greek lecturer in his college, in which department he acquitted himself with great applause. Fuller speaks of him in the highest terms as a commentator of Aristotle's Rhetoric. He had hitherto been zealously attached to the Papist religion, while his brother William was equally zealous for the Reformation. The difference in their sentiments leading them to frequent conferences and disputations, they made converts of each other, William becoming a determined Papist, and John a steady Protestant. He frequently appeared in the pulpit, and was greatly admired as a preacher. In the year 1588 he was admitted to the degree of doctor of divinity, and soon afterwards the fame of his great learning induced queen Elizabeth to appoint him professor extraordinary in that faculty at Oxford; after which he gave him the deanship of Lincoln, which he held only a short time, when he exchanged it for the prebendship of Corpus Christi college, of which he was a fellow. He made this exchange from his attachment to an academical life, and his love of retirement and study. Similar motives led him afterwards to refuse a bishopric which Queen Eliza-

beth offered him. He retrieved the finances of his colleges, which had been suffered to fall into dilapidation, and he restored its decayed discipline, strictly obeying the statutes himself, and compelling all the other members to observe them. After the accession of James, he was appointed, with Dr. Sparks, Mr. Claderton, and Mr. Knewthubs, to appear on behalf of the Puritans in the pretended conferences at Hampton Court; of which we have a full account in the second volume of Neal's "History of the Puritans," by Dr. Toulmin, p. 10-20. Dr. Raynolds did not on this occasion act according to his usual spirit, and, suffering himself to be browbeaten by the royal tyrant, lost much of the respect which his character usually laid claim to. It was at the conclusion of this conference, that the king said to Dr. Raynolds and his friends, in answer to their arguments: "If this be all your party hath to say, I will make them conform themselves, or else I will harry them out of the land, or else do worse, only hang them, that's all." When James gave directions for undertaking a new and more correct translation of the bible, Dr. Raynolds was one of the Oxford divines who were commissioned to give a new version of the four greater prophets, the book of Lamentations, and the twelve minor prophets. While employed in this great work he was feized with the gout, under which he had been a sufferer many years, and which at length proved fatal to him. In the midst of the feverish pains, he persevered in the task assigned to him, and once a-week his fellow-labourers at Oxford regularly assembled in his apartments, where they compared the fruits of their respective studies, determining what appeared to them to be the most faithful translation, till they had accomplished their task. Dr. Raynolds died in the year 1607, highly respected for his erudition, his piety, his modesty, and humility. Several of his biographers speak of him in the highest terms. Wood says he was most prodigiously seen in all kind of learning, and had turned over all writers, profane, ecclesiastical, and divine, all the councils, fathers, and histories of the church. He was author of many theological works, of which we may mention "De Romanx Ecclesiæ Idolatria, in Cultu Sæculorum, Reliquiarum, Imaginum," &c. 1596; and "Cenfura Librorum Apocryphorum Veteris Testamenti, adversus Pontificios," which was a pithumous work, and printed at Oppenheim, in Germany, 1611, in 2 vols. 40s.

RAYPOUR, in Geography, a town of Hindoostan, in Bahar; 40 miles N.W. of Chuprah.

RAYULLAH, a town of Hindoostan, in Bahar; 32 miles E. of Bahar.

RAYPOUR, a town of Bengal; 55 miles W.S.W. of Burdwan. N. lat. 22° 48'. E. long. 87° 5'.—Alfo, a large and commercial town of Hindoostan, in the country of Ruttunpoor; 55 miles S. of Ruttunpoor. N. lat. 21° 24'. E. long. 82° 28'.

RAYPOUR, or Ray-Gaut, a remarkable pass on the Behar river, about 17 or 18 miles from Noorpoor; situated a considerable way within the level country of the Panjab.

RAYTE, or RYCHES, in Ichthyology, a name given by Joanna Cuba, Albertus, and others, to the common ikate, or flaire. See Rayte Baits.

RAZANT. See RASANT.

RASANT Flank. See Flank.

Rasant Line of Defence. See Defence.

RAZBOINIKOVA, in Geography, a town of Russia, in the government of Irkutik, on the Angara; 56 miles N.W. of Balanganakai.

RAZBOINOI, a fort of Russia, on the Ural; 92 miles E. of Orenburg.
RAZE. See Tems.

Raze, in the Menege. A horse is said to have raze'd, whose corner teeth cease to be hollow; so that the cavity, where the black mark was, is filled up; that is, wholly disappears, and the age of the animal cannot be known with any degree of certainty. See Mark.

Razi, in Biography, one of the famines of the famous Mufdalian Merchandize Ben Omar Ben Khatid Rzi, Al Timmi Al Bari, a native of the city of Rez, in the Persian Iraus, of which the word Razi is the appellative. He was born in the year of the Hegira 543, corresponding with 1481 of the Christian era, and became one of the most celebrated doctors. His knowledge was not confined to the learning usually taught in the Mohammedan schools, but it comprehended likewise the sciences imported into the East with the writings of the Grecian fages. He was, moreover, a very eloquent preacher both in the Arabic and Persian languages. By these qualifications he acquired the favour of several princes, particularly of a fultan of the Gaurid dynasty, who erected a college for him in the city of Herat in Chorafan. He was driven from this situation by the intrigues of Cadi Abdalmegid, of the sect of Kera-mians, who contended that the deity was corporeal, and of human shape. Having challenged Razi one day to a public disputation on the attributes of God, he was too confounded by the superior reasoning of the latter in defence of the divine spirituality, that he became his bitter enemy, and feit from every opportunity of calumniating him to the fultan, as a man who, under the cloak of philosophy, concealed irreligious and impious notions. By his pernicious, the prince banished Razi from the city, but he soon reptied of his ball decree, and recalled him. This happened in the year 606 of the Hegira. He was author of an 'Introduction to the most sublime Mysteries for the Use of Men of Genius,' in which he explains the principles of the Mohammedan philosophy; and several other pieces. 'Select Astronomical Researches' have been attributed to him, but perhaps on insufficient authority.

Razi is also the surname of a celebrated philosopher, chemis, and astronomer, called Mohamed Ben Zakaria, a native of the same city, in the preceding, who flourished under the caliphate of Moctedder of the dynasty of the Abbassides. He died about the year 922 of the Christian era.

Razimierz, in Geography, a town of the duchy of Warsaw, situated between Sieprzeka and Posen, where the unfortunate count Pakul was broken alive on the wheel, and impaled by order of Charles XII. of Sweden in 1768.

Razniplaiia, a fort of Uffia, in the government of Upha, on the Ural; 56 miles S.W. of Orenburg.

Razois, Port, a port at the S.W. extremity of the coast of Nova Scotia, and N.E. of cape Negro.

Razor, a well-known edged instrument used in shaving. Heat appears to give a partial increafe of tenacity to a razor's edge, probably because the edge cools fallet, contracts, and is stretched.

Razor-Bill, in Ornithology, the common English name of the alca, a web-footed bird with no hinder toes, common on our fla-fores. See Alca Torda.

Razor-Fish, in Ichthyology, the Coryphaena novaecala of Linnaeus, having the head and fins barred with blue and lines. See Novacula.

Razor Iland, in Geography, a small illand on the coast of Brazil; 12 miles S. of Rio Janeiro.

Razuda, a town of Hindoostan, in Guzerat; 40 miles E.S.E. of Chittagor.

Re, an illand in the Atlantic, near the well coast of France, about 16 miles long, and 3 broad; separated from the coast of Vendee by the ftraits of Breton, which are about 7 miles wide. The principal town is St. Martin de Re. N. lat. 46° 13'; W. long. 1° 12'.

Re, in Commerce. See Rees.

Re, in Grammar, c. c. an inappratable particle, or preposition, prefixed to the beginning of words, to vary, double, or otherwise modify their meaning.

The participial re was first introduced by the Latins, from whom it is borrowed into most of the modern tongues. Prifcian derives it from reto, backwards; others rather derive reto from re; others derive re from the Greek εἷς, εὖ, or from λευ, I flow.

The effect of the re is various: usually it signifies again, rearum, oxon; as in rejoin, re-sign, re-frame, re-cours, re-bound, re-cite, re-hear, re-recognize, re-compare, re-double, re-liquid, &c.<

Sometimes it stands for contra, ad, again; as in re-luctance, re-cumbent, re-line, &c.<

Sometimes for ex; super, over, as in re-dundant; sometimes for πρ, longe, sur, as in re-moving, &c.<

Re, in Mufs, the name of the second of the keys in the three hexachords of Guido, C, C, and E. See Solmisation, Gamut, Hexachords, and Mutations.

Re Alto Casicia, II, the Italian title of a comic opera, taken from our "Miller of Mansfield." It was fet to music for our opera-house in 1763, by Alessandri, a young composer of promising abilities. He was husband of Lu Guadagni, the original "Buona Figliuola" in Italy, and fitter to Gaetano Guadagni, the celebrated fanger. But the Miller of Mansfield was firft formed into a comic opera for Paris, by Sedaine, and fet by Montfigni, under the title of "Le Rol et le Fermier," in 1752.

Re Tendoro, II, a comic opera, founded on the adventures and vicissitudes of the unfortunate Theodor, king of Corsica. The music of this drama is one of the innumerable instances of the fertility of Pafellio's pen. It had been performed all over Italy and Germany with the greatest applause, previous to its being brought on our flage. The music, that was not changed, is extremely original and pleasing, particularly the finales. There was a mixture of airs by Corelli, Mascetti, and Storace, but behind destroy-'ing the unity of style, the certainty of there being merit of some kind or other in every composition of Pafellio, inclines lovers of music to lament that any of his airs should be changed or omitted.

REA, in Geography, a river of England, which runs into the Tame, 3 miles N.E. of Birmingham.

Rea, Lough, a lake of Ireland, in the county of Gal-way, on the border of which is the town of Loughrea. See Loughrea.

Reach, in Sea Language, the distance between any two points on the banks of a river, in which the current flows in a straight uninterrupted course.

Re-action, in Physics, the action by which a body acted upon, returns the action by a reciprocal one upon the agent.

The Peripatetics define re-action to be that which a passive body returns upon the agent, by means of some quality contrary to that received from it, in the same part with which the agent acted, and at the same time; as if water, while it is heated by the fire, does at the same time cool the fire.

It was known, even in the schools, that there is no action in nature without re-action; and it was a maxim among them, omn'e agents, agendo repulsur.

But the equality of the actions was not known. Sir Isaac Newton established it as one of the laws of nature, that
action and re-action are equal and contrary; or that the mutual actions of two bodies, striking one against another, are exactly equal, but in contrary directions; or, in other words, that by the action and re-action of bodies one on another, there are produced equal changes in each; and those changes are impelled towards directly contrary parts or ways of nature.

Some of the school-philosophers deny any such thing as re-action, properly so called, at all; urging, that action arises only from the ratio of the greater inequality; that is, we are only to account for action the executs of action, or what the agent does more than is returned by the patient. But the equality between action and re-action sets aside this exception.

READ, in Geography, a river of England, in the county of Northumberland, which runs into the Tyne, 10 miles N. of Hexham.

READ HEAD, a cape on the E. coast of Scotland. N. lat. 56° 35'. W. long. 2° 58'.

READFIELD, a post-town of America, in Kennecotta county, and district of Maine, bounded on the E. by Hallowell, and separated from Sterling on the W. by the eastern branch of the Androscoggin river; 8 miles W. of Hallowell, and 190 N.E. of Boston. It contains 1396 inhabitants.

READING, Joins, in Biography, organist, first at Lincoln, then at Hackney, and finally at St. Dunstan's church in Fleet-street, London. He was a scholar of Dr. Blow, and Stanley's first master. He published Hymns early in life, for psalmodists in parochial congregations; and, lastly, a work engraved on copper, which he called "A Book of my Anthems, with a Thorough-bafe, for the Organ or Harpsichord." He died in 1766, far advanced in years.

Reading, in Geography, a borough and market-town in the hundred of Reading, and county of Berks, England, is 38 miles W. by S. from the metropolis. It is a town of considerable extent and importance, and contains, according to the parliamentary returns of 1811, 2032 houses, and 10,788 inhabitants.

Historical Events.—Reading is unquestionably of very great antiquity; but whether it is indebted for its origin to the Britons, the Romans, or the Saxons, is unknown. Conjectures, however, have been hazarded on the subject by various writers. Camden thinks its foundation ought to be referred to the Britons; Leland calls it the Pontes of Antoninus; and Dr. Becke, the learned professor of modern history at Oxford, considers it the Calleva of Richard of Cirencester. But the circumstances which are alleged in favour of these opinions, by their respective authors, are far from being satisfactory. This place is first mentioned in history, under its present appellation, in the year 871; at which time it is described by Asser as being a fortified town, belonging to the Saxon kings, but then occupied by the Danes invaders, who had retreated hither after their defeat at Englishfield. The victorious Saxons immediately invected the town; but their enemies, having received reinforcements, attacked the besiegers with such impetuosity, that, after an obitiate contest, they deemed it prudent to retire to Atcham. Hither they were followed by the Danish forces, which were again overthrown, and driven back to Reading. Here the latter remained unmolested till the following year, when they marched to London. In the reign of Alfred, who restored the throne of Wessex soon after this event, the Danes once more feizd upon Reading, and they doubly possessed it occasionally during their incursions in the tenth century. Throughout that long period of incessant hostility and depredation, however, this town seems to have escaped any very serious disaster; but in 1006 it was reduced to ashes by Sweyn, king of Denmark, along with its famous nunner, said to have been founded by Elfrida, widow of king Edgar, as an atonement for the murder of Edward the Martyr. Reading soon recovered from this disaster, and in the course of a century afterwards became a place of considerable importance. In 1121 King Henry I. laid the foundation of its magnificent abbey, in which his remains were subsequently interred, according to his own desire. Stephen, who usurped the throne after Henry's death, built a castle here, which was surrendered to his antagonist Henry Fitz-Empress, who no sooner obtained the crown, than he ordered it to be demolished; so that even the site of it is now uncertain. That monarch, however, otherwise evinced much partiality for Reading. Here he passed much of his time, and convened a parliament, as also an ecclesiastical convocation, in which Baldwin was elected archbishop of Canterbury. The abbey church was finished in this reign, and dedicated in presence of the king. In 1185 he came hither from London, to receive Heraclius, patriarch of Jerusalem, who presented him with the keys of the holy sepulchre, and the royal banners of Jerusalem, which Henry returned. In the reign of his successor, Richard I., a convention for the trial of Longchamp, chancellor and bishop of Ely, who had been appointed regent of the kingdom during the king's absence, was held here. King John also held a convention in this town, in 1206; and in 1212 a council was convened here by the pope's legate, for the purpose of effecting a reconciliation between that infatuated prince and the exiled bishops. In 1213 the king met the legate and barons at the abbey, and held a parliament. King Henry III. spent his Christmas at Reading in 1226; and twice during his reign summoned the estates of the realm hither, for the transaction of national business. He was the first monarch who granted a charter of incorporation to the town. In 1346, Edward III. held a great tournament here; and in 1359, the marriage of his son, John of Gaunt, with Blanche, daughter of Henry, duke of Lancaster, was solemnized in the abbey church. In 1384, Richard II. and his court, together with the mayor and aldermen of London, being assembled at Reading, John Northampton, the preceding mayor of that city, was convicted before them of fœtidous practices, and sentenced to perpetual imprisonment. In 1389 a great council was held at Reading, at which the king and his barons were reconciled by John of Gaunt. Parliaments were held here also in 1440 and 1451; in the former of which the order of nobles called vilcounts was first established; and in the year following, the parliament adjourned hither from Westminister, on account of the plague. King Edward IV.'s marriage with Elizabeth, lady Grey, was first acknowledged at Reading, in 1464; on which occasion she made her public appearance at the abbey, conducted by the duke of Gloucester and the earl of Warwick. In 1466 parliament was a second time adjourned to Reading, to avoid the plague. King Henry VIII. frequently resided here, having converted the dissolved abbey into a palace. His son, king Edward VI., visited this town in 1552, when he was met by the mayor and aldermen at Colts-Crofts, and presented with two yokes of oxen; the mayor riding before him, uncovered, to the palace. The fame ceremony was repeated, when Reading was visited by the bigotted Mary, and her husband, King Philip of Spain. Queen Elizabeth was a frequent visitant here, and had a seat in the church of St. Lawrence.

Early in the reign of Charles I., when the plague raged
with great violence at London, the courts of chancery, king's bench, and common pleas, were held here, as were likewise the court of exchequer, the court of wards and livery, and the court of requets. In 1624, Reading was a parliamentary poll, but the garrison, being defective as to ordnance and ammunition, quitted the town, without refitance, on the approach of a party of the king's horse. In consequence of this event it became a royal garrison, and continued to be so till taken by the earl of Essex in April 1643, after a siege of eight days. The king, however, again recovered it in September the same year, and held it till May following, when he ordered the works to be demolished, and evacuated the town. After this event Reading was frequently occupied as the head-quarters of the parliamentary army, and was consequently much improved by the contributions levied upon its inhabitants for the support of the military. In 1688 the army of king James II. was quartered in this town, but quitted it on the approach of the prince of Orange. On this occasion a skirmish took place in the market-place between two detachments of horse, which terminated in favour of the Protestant interdict, and is still commemorated, by bell-ringing, on the anniversary of its occurrence. Queen Anne visited Reading in 1700, when she was received by the corporation in state, and presented with forty broad pieces of gold in an elegant purse made for the occasion.

Municipal Government.—Reading claims the honour of having been originally constituted a city, by charter from Edward the Confessor. This claim, however, is extremely questionable; and at all events we feel convinced that the ancient guild was nothing more than an association of mechanics and traders for their individual benefit. The first monarch who conferred upon Reading the privilege of separate jurisdiction was Henry III., in the 37th year of his reign. His charter was subsequently confirmed by all his successors, but without any material alterations, till the reign of Henry VI., when the corporation is still mentioned by the title of the mayor and burgesses. Thus it continued to be denominated till queen Elizabeth divided the burgesses into capital and feodary, and declared the mayor and them to be a corporation for the borough. That privilege further conferred upon the corporation considerable estates. Charles I. authorized aldermen to be elected, and invested the mayor and them with ample powers for the government of the town. This charter was confirmed, after the restoration, by his son Charles II., and is the one under which the corporation now acts. By it the officers are declared to be a mayor, twelve aldermen, and the same number of capital burgesses, the mayor, and his deputy, (the preceding mayor,) the senior alderman, the bishop of Salisbury, and his chancellor, being justices of the peace for the borough, and empowered to hold feisions, and a court of record. The recorder is an officer added by Charles II., who likewise first acknowledged the townclerk. Reading sent members to parliament from the time of the earliest records. Before 1716 the right of election was vested in the freemen not receiving alms, and in the inhabitants paying foot and lot; but in that year it was limited, by a decision of the house of commons, to the inhabitants paying foot and lot only. The number of voters is estimated at 560, and the mayor is the returning officer. The spring alizes for the county are held at this town, as are likewise the Epiphany feisions, but the summer alizes are held at Abingdon, and the Michaelmas; either there or at Reading, as the magistrates may judge most convenient.

Reading is a town of considerable extent, situated on both banks of the river Kenet, which separates itself into several branches in pursuing through the town. It contains three parishes, St. Giles, St. Mary, and St. Lawrence, and is divided into five wards, called the High-ward, New-ward, Minster-ward, Old-ward, and London-ward, for each of which a constable is appointed. Formerly it was a place of great trade in woollens, but that manufacture fell to decay during the fourteenth century, and has never since revived. At present the chief manufactured products are, coarse linens, (such as sheeting, fall-cloth, floor-cloth, and packing goods,) gautes, crapes, mufflins, ribbons, hat-bands, shoes, ordinary cloths, and other similar articles. Thee afford employment to a great portion of the inhabitants among the lower orders; but the principal support of the town arises from its water communications with London, Bath, and Bristol. The articles exported are, flour, of which 20,000 sacks are sent annually to the metropolis, timber, bark, straight hoops, linen, wool, cheefe, beer, and a variety of minor articles; in exchange are received groceries of every kind, iron, spirits, fir timber, deals, flates, Portland stone, bricks, hemp, flax, hides, leather, coals, Bath free-floame, Birmingham goods, &c. For the convenience of trade, several wharfs are formed at Reading, and many improvements have been lately made in the internal navigation of the diocese at large.

This town, from time immemorial, has been noted for its markets, which are held weekly, on Wednesday and Saturday. The Wednesday’s market is chiefly for fruit; but that of Saturday embraces corn and every article of provision. The spot on which the corn market is held, is a spacious piece of ground, of a triangular form, environed by commodious shops for the accommodation of people attending the market, who may be supplied here with colonial or manufactured goods cheaper than in any other town in the county. This market-place is kept in repair by the corporation, for which they are entitled to take one pint out of each sack of corn sold in the market, amounting to about 54,000 quarters annually. The provision market buildings adjoin to the corn market-place, and form a long square, consisting of two ranges of butchers’ shops, and the other half of apartments for the market-women, who bring butter, eggs, poultry, &c. for sale. At the southern end of this building is a square open area for fifthmongers’ and hucksters’ stalls, and next to this, and fronting a street called Fisher-street, is a large square gate-way, over which is the house occupied by the clerk of the market. Besides these market-places, there is another for the sale of hogs pigs, conveniently situated between Friar-street and Broad-street. This is private property, but the corporation receive the toll. At Reading are four annual fairs, one on the 2d of February, another on the 1st of May, a third on the 25th of July, and a fourth on the 21st of September. The three first are chiefly for the sale of horses and cows; but the last is also a statute fair for the hiring of servants, and is further remarkable for the quantity of cheefe brought hither from the counties of Gloucester and Wilts. Hops are also plentiful at this fair.

The houses of Reading are mostly constructed of brick, and are generally disposed in regular streets, some of them very narrow, which have been paved under the authority of an act of parliament, passed in the year 1785.

The principal public buildings and institutions in the town are the three churches of St. Lawrence, St. Mary, and St. Giles, and several dissenting meeting-houses, the town-hall and free-school, the blue-coat school, the green school, the foundation school, the school of inditry, the Lancaërian school, the school for national education, the theatre, and the county gaol.
The church of St. Lawrence was chiefly erected towards the close of the 17th century, and is partly constructed of materials taken from the buildings of the abbey. Among the parts of it, so sufferers from the monastery, is a large doorway, which is composed of a circular arch, ornamented with rich mouldings, from which were suspended on each side the arms of the abbey; but these are now nearly obliterated. This doorway is flanked with niches, in which statues formerly stood. The advowson of the church belongs to St. John's college, Oxford. St. Mary's church is somewhat more ancient than that of St. Lawrence, having been constructed about the year 1547, in the head of a previous one, which had gone to decay. Some portions of this building have evidently belonged to an older edifice, particularly a window over the west door, which is in the early pointed style of architecture. St. Giles's church was probably constructed at the commencement of the 12th century.

The tower only is modern, the ancient one having long been demolished during the civil war. The livings of both the churches last mentioned are in the gift of the lord chancellor. The principal meeting-houses for dissenters are the Calvinistic or Independent meeting-house in Broad-street, a Baptists meeting-house and a Quakers meeting-house in Church-street, a Methodist chapel in Castle-street, and another in Minster-street, a Cudworthian and an Unitarian meeting-house in London-street, and a Catholic chapel in Vafern-lane. Another meeting-house for Baptists has also been lately erected in Sievier-street.

The town-hall and free-school form one building; the free-school occupying the ground story, and the hall, court-room, and offices, the floor above. The free-school was established in the reign of Henry VII., by John Thorne, abbot of Reading, with the funds of a suppressed almshouse. This school has two scholarships in St. John's college, Oxford, the gift of Sir Thomas White, in 1557. Julius Palmer, one of the masters of this school, fell a martyr to his Protestant tenets in 1556. The blue-coat school, which is so named from the drefs of the scholars, was founded in 1676, by Mr. Richard Aldworth, who bequeathed 4000l. for the support of a master, lecturer, and twenty boys. The present school-house is of late erection, and consists of a centre and two wings. Several donations and bequests having been made to this establishment by various persons, it now usually supports about 48 boys. The green school is situated in Broad-street, and is appropriated for the education of the daughters of decayed tradesmen, residents in the town, and of orphans, who have been left unprovided for by their parents. The inhabitants of Reading are indebted for the institution of this school to the Rev. Charles Sturges, the Rev. Dr. Nicholls, and the Hon. and Rev. W. B. Cadogan, former vicars of the three parish churches belonging to the town. It is supported by annual subscription, and the proceeds of different donations and bequests. In the foundation school, founded in 1766, eight male and eighteen female children are taught to read. It was instituted with a legacy left for that purpose by Mr. Joseph Neale. The school of industry originated under the patronage of Mrs. Cadogan, for female children, and is supported by the voluntary contributions of ladies in the town. The Lancingian school, established in 1810, is situated in Southampton-street, and is attended by about 350 boys, who are nominated by the subscribers individually. The school for national education was opened in September, 1813. It is founded on the plan of instruction recommended by Dr. Bell, and is chiefly supported by the clergy of the town and county. Both these institutions are calculated to be highly beneficial to the rising generation. Besides these seminaries of education, there are in Reading several Sunday schools, all the children attending which receive a suit of clothes annually, from a fund provided by the bequest of Mr. Edward Simeon, who clothed them in the same manner during his life-time. The theatre of Reading is a neat and convenient building, lately erected, under the act for regulating provincial theatres. The gaol was built in 1793, on the site of some of the abbey ruins. It is a large edifice, and contains commodious apartments for the keeper, a neat chapel, an infirmary, and a room for the reception of the magistrates, in the centre; and two wings, one for male, and the other for female prisoners, with yards, cells for refractory individuals, &c.

Besides the above public buildings and establishments, there is a public library lately established at Reading, under the name of the "Reading Institution," also a dispensary, which is attended by some of the medical gentlemen of the town. The house is the property of the corporation, and the general expences are defrayed by subscription. The Oracle may likewise be reckoned among the public buildings of Reading. This structure was erected by the mayor and burgesses, in conformity to the will of John Kendrick, who left 7500l. "to build a strong house of brick, fit and commodious to let the poor to work therein." The funds of this charity having been at different periods greatly abused and misapplied, the subject has been several times before the supreme courts of justice. The tefator's object, in bequeathing his large legacy, was the improvement of the woollen trade; but instead of this, it was perhaps the first occasion of the decay of that manufacture, by enabling such as could obtain its advantages to underall those who were not so fortunate. The same complaints are made against it, with respect to the manufactures now carried on in it, and, as we suspect, not without some show of reason.

Monastic Establishments.—As already mentioned, the earliest religious institution at Reading was a monastery for nuns, founded by Elfrida, the mother-in-law of Edward the Martyr. This nunsry was founded in 979, and was destroyed, in 1009, by the Danes. The precise site on which it stood is uncertain, but there can be no doubt of its existance. It appears from the Domesday-book, and also from Tanner's Notitia, that another nunsry was established here at a later period, but nothing of its history is known. The abbey, the ruins of which are still sufficient to attest its extent and importance, was founded by Henry I. in 1121. The occupied a spot of ground, equal, if not superior, to any in Berkshire for fertility of soil and beauty of situation. This spot comprehended about thirty acres, and was environed on three sides by a massive and lofty wall, and on the fourth by the river Kennet. Exterior to this wall was a piece of ground, about fifty yards wide, (like the pomarium that surrounded the Roman cities,) which it was not allowable either to cultivate or build upon. It had four entrances to it, defended by arched gateways, and having battlements on their tops similar to those on the walls. Within there was the outer court, whence another gate-way led into the inner court. Part of this building remains, and is composed of bricks, chalk, and stone; and, from the diffimilarity of styles which it exhibits, has evidently undergone many alterations and repairs. Some of it is probably as late as the reign of Henry VII., though other portions of it are, undoubtedly, of much higher antiquity. The inner court conducted to the principal entrance to the abbey, the situation of which, owing to the ground having been since built upon, and the confusion occasioned by throwing up the ramparts in the civil war, cannot now be accurately determined. The only entrance on this side at present is through an arched passage, opening into the south-east corner of the cloisters, which is certainly
READING.

The other monastic institutions in Reading, besides those already noticed, were two convents for Franciscan or Grey friars, St. Edmond's chapel, and Colney chantry. One of the convents was founded about the middle of the thirteenth century, soon after the first appearance of the Franciscan order in this country. Its original situation was on a marshy ground adjoining the Caverham road, and still called the Friery Mead; but in 1285 the friars removed to their inquisitorial residence, at the western extremity of Friery-Street. After the dilution this house was appropriated as a workhouse for the poor; and part of the church now forms the borough prison. This building is in the early pointed style, and has at its western end a very beautiful lancet window. The other convent stood in Castle-street, probably on the spot now occupied by the Methodist chapel. This institution seems to have been on a very small scale, though it is mentioned by Leland as "a faire house of Grey freres." St. Edmond's chapel stood on the rising ground, called Chapel Hill, near the borough prison. It was founded, in 1284, by Lawrence Burgers, then bailli of the town. In the civil war it was converted into a fort; and afterwards, about the year 1750, was demolished, and another chapel erected in its stead on Battle-Farm. Colney chantry was instituted by one of that family in the reign of Richard II., for the souls of king Edward III., of Thomas Colney, John Colney, and William Catour. It had distinct incumbents of its own, and was under the patronage of the corporation.

Reading has given birth to several persons of eminence, Sir Thomas White, founder of St. John's college, Oxford, is said to have been born here; but Fuller affirms that he was a native of Rickmanworth. Archibishop Laud was born in this town in 1573, having been the son of William Laud, then a clothier in Broad-street, who, as the archbishop himself told lord Say, had borne all offices in the corporation, save the mayoralty. John Blagreave, the mathematician, is also commonly reputed to have been a native of Reading; as was Joseph Blagreave, a celebrated astrologer, who does not seem to have been related to the mathematician. The other distinguished natives of Reading were, Sir Thomas Hare, Sir John Barnard, a noted alderman of London; James Merrick, the translator of the Psalms; William Baker, a learned printer; Sir Conflantine Phipps, lord chancellor of Ireland; and Dr. Phanuel Bacon, author of several dramas, &c.

The vicinity of Reading presents several objects worthy of notice. At a short distance to the southward, close to a place called Catfgrove-lane, may be seen a remarkable stratum of oyster-shells, imbedded in a vein of sea-lard, at least twenty fathoms beneath the surface of a hill. This stratum is from one to two feet in thickness, and extends through a circumference of five or six acres of ground. Mixed with the shells is a considerable quantity of small teeth, apparently of fish. Caverham, formerly a seat of the Craven family, and afterwards of the Cadogans, is situated nearly on the road, on the north bank of the river Thames. The house was built by the earl of Cadogan, in the reign of George I., but has since undergone material alterations. In the old manor, Anne of Denmark, queen to James I., was splendidly entertained by lord Knowles, when on her journey to Bath, in 1613. At the time Charles I. was a prisoner at Windlor, the parliament, through the mediation of general Fairfax, permitted him to visit Caverham Lodge, where all his children who were in England then resided, in the custody of the earl of Northumberland. In the hamlet of Woodley is a very pleasing feat, belonging to lord Sidmouth; and two miles to the westward
wellward is another, the property of the Blagrave family. The park is very extensive, and is noted for fine venison. South-eaft, on the same line, is White-Knights, the seat of the marquis of Blandford. Sunning, celebrated in history as having been for some time the seat of the see of Wilts, and subsequently the cité of one of the palaces of the bishops of Salisbury, is a village three miles to the eastward, on the road to Maidhead. Lelund mentions the bishop's palace as standing in his time. It was given by bishop Ghealt, along with the manor, to queen Elizabeth, in exchange for estates in Dorsetshire. The antiquity of this place is strongly marked by the sepulchral monuments in the church. Close to Sunning is an elegant mansion, the seat of Charles Fysh Palmer, esq. Lysons's Magna Britannia, 4to, Berkshire. Beauties of England and Wales, vol. ii., by John Britton and E. W. Brayley, 1801. The History and Antiquities of Reading, by John Mann, 4to, 1814. From the latter work, the chief and most essential parts of this account have been obtained: and those who wish to peruse the most copious and authentic history of Reading will procure this volume.

Reading, a township of America, in Fairfield county, Connecticut, S. of Danbury adjoining. It contains 1747 inhabitants.---Alto, a large township of Middlesex county, in the state of Massachusets, incorporated in 1644, and containing 2278 inhabitants, many of whom are employed in the manufacture of shoes, from 2 to 300,000 pair being annually exported; 12 miles N. of Bolton.---Allo, a township of Vermont, in Windor county, W. of Windsor, adjoining. It contains 1565 inhabitants.---Allo, a beautiful post-town, and the capital of Berks county, Pennsylvania, situated on the N.E. side of Schuylkill river; 54 miles N.W. of Philadelphia. This town is regularly laid out, and flourishes: its inhabitants are chiefly German: the borough and township contain 3462. The public buildings are, a stone gaol, a court-house, an elegant church for German Lutherans, erected in 1793, a church for Calvinists, and one for Roman Catholics, a meeting-house for Friends, and a large edifice for the public offices. In the neighbourhood are 10 fulling mills, and several iron-works: and at the distance of 10 miles, on the road to Harrissburg, is a spring, about 15 feet deep and 30 feet wide, from which issue a copious stream, containing some fine trout. In 1795 the sum of 12,000l. was voted by the county for building a stone arched bridge over the Schuylkill, at this town, on the high road to Harrissburg. N. lat. 40° 21'. W. long. 75° 55'.---Alto, a township of Adams' county, in Pennsylvania, containing 732 inhabitants.

Reading. See Lectio. Reading of a Deed. See Deed.

READINGS, in Criticism. Various readings, varie lectiones, are the different manners of reading the text of authors in ancient manuscripts; where a diversity has arisen from the corruption of time, or the ignorance of copyists.

A great part of the business of the critics lies in settling the readings, by confronting the various readings of the several manuscripts, and considering the agreement of the words and sense. The various readings in the bible, (see Hebrew Bibles,) and in the classic authors, are almost innumerable.

Readings are also used for a sort of commentary or glosses on a law, text, passage, or the like; to shew the sense an author takes it in, and the application he conceives to be made of it.

READINGTON, or RIDDENTON, in Geography, a town of New Jersey, in Hunterdon county; 17 miles N.W. by W. of New Brunswick. It contains 1797 inhabitants.

READ'S BAY, a road for ships on the W. coast of the island of Barbadoes, between Holetown and Speight's-town; half a mile broad. Ships may anchor here in safety, in fix to twelve fathoms water, the ground being soft ooze, defended from all winds, except the west, which blows right into the bay. N. lat. 1° 5'. W. long. 59° 47'.

REDSBOROUGH, or REEDSBOROUGH, a post-town of America, in Bennington county and state of Vermont; 435 miles from Washington. It contains 410 inhabitants.

REE-FORRESTED, is where a forest, having been defatted, is again made a forest. As the forell of Dean was, by act of parliament in the 20th of king Charles II. See Forest.

RE-AGGRAVATION, in the Romish Ecclesiastical Law, the last monitory, published after three admonitions, and before the last excommunication.

Before they proceed to fulfillate the last excommunication, they publish an aggravation, and a re-aggravation. Fievret observes, that in France the minister is not allowed to come to re-aggravation, without the permission of the bishop or official, as well as that of the lay judge. See Excommunication.

REAH, in Geography, a town of Syria, in the pachalic of Aleppo, situated in a country that abounds with olives, of which considerable quantities are prepared, and sent to Persia and other parts. This is the residence of an Aga; 36 miles S.S.W. of Aleppo.

REAL, RALE, is applied to a being that actually exists; in which feme it coincides with actual. Real, in Law, is oppoied to personal.

REAL ACTION, that by which the plaintiff lays title to land, &c. See Action.

Customs are said to be real; that is, they determine all inheritances within their extent; and none may dispone of them, but according to the conditions allowed by the customs where they are fixed.

REAL altitude, affets, charater, chattels, covenant, distinction, dignity, estate, horizon, optic place, patronage, privileges, qualities, rent, services, suit, and writs. See the several substantive.

REAL, in Commerce, a Spanish money of account, of which there are four different sorts. The real vellon is that which is most general; it consists of 5½ quarts, 17 ochavos, or 34 Maravedis vellon. Madrid, and the whole of Catali, with most of the adjacent provinces, and 5o Bilboa, Malaga, and Galicia, keep accounts in reals and Maravedis vellon. The real of new plate (real de plata nueo, or provincial) is double the real vellon; it is worth 17 quarts, or 34 ochavos; and it is also reckoned at 34 Maravedis of new plate. This real is represented by an effective coin of base silver, but books are not kept in any part of Spain in this money.

The real of old plate (real de plata antiqua), mostly called the real of plate, is chiefly used in foreign commerce and exchanges; it is worth 16 quarts, or 32 ochavos; and it is also reckoned at 34 Maravedis of old plate. Cadiz and Seville keep accounts in reals and Maravedis of old plate.

The real of Mexican plate (real de plata Mexicano) is used in transactions with Spanish America, where accounts are mostly kept in hard dollars, reals, and quarters, and sometimes in sixteens; 8 Mexican reals make 1 hard dollar (pezo duro): this coin is worth 10 reals of new plate, 10½ reals of old plate, or 20 reals vellon. Thus, 1 real of new plate = 2 reals vellon; and 4 reals Mexi
can = 5 reals of new plate: 64 Mexican reals = 85 reals of old plate: 2 Mexican reals = 5 reals vellon: 16 reals of new plate = 17 reals of old plate: 17 reals of old plate = 32 reals vellon. The pilote of exchange (doblón de plata) is worth 32 reals of old plate, 60 reals of new plate, 8 Maravedis vellon. The dollar of exchange (peño de plata) is worth 8 reals of old plate, or 15 reals 2 Maravedis vellon. The ducat of exchange (ducado de plata) is worth 11 reals 1 Maravedi of old plate, or 20 reals 25½ Maravedis vellon. But, in commercial transactions within the country, the dóbło is reckoned only at 60, the peño at 15, and the ducat at 11 reals vellon.

The coins now current in Spain are as follow:

In gold.—The dóblo of 8 escudos, or quadruple pilote, p affine for.

The dóblo of 4 escudos, or double pilote.
The dóblo de Oro, or pilote.
The escudo.
The corona, or vein-

ción de Oro.

In silver.—The dollar, or peño duro.
The half dollar, or escudo vellon.
The pećeta Mexicana.
The real of Mexican plate.
The real of provincial plate.
The real vellon.
The piece of two quartos.
The quarto.
The ochoavo.

From 1730 to 1772, the gold was 22 carats, and the silver 11 dineros fine (the dínero = 24 grains); but in 1772 the gold was reduced to 21½ carats, and the silver to 10½ dineros fine, the pećetas and reals being reduced to 9½ dineros fine. In 1786 the standard of the gold was again reduced to 21 carats for the different dóblos and their divisions, and to 20½ carats for the corona and vein-

ten de Oro. For the value of the pilote, see PISTOLE.

The dollar (coined since 1772) contains 374½* troy grains of fine silver, or 405½* grains of English fine silver: its value therefore in English silver coin is 4½ 4½ d.; and the half dollar in proportion. The value of the peño of plate, or dollar of exchange, in English silver coin, is 30½ d.; of the dóblo of plate, or pilote of exchange, 13½ d.; and of the ducat of plate, 42 6½ d. The real of old plate is worth about 5½ d.; and the real vellon 2Æ d. nearly; or more accurately, 1½ sterling = 48 reals, 203½ Maravedis of old plate, or 91 reals 17 Maravedis vellon.

By the reports of average assays lately made on the quadruple and dollar at the London mint by order of the bank of England, the quadruple weighs 17 dwt. 8 gr.; its fineness 43 ½ gr. worse than English standard; hence its value in English gold coin is 3½ 4½Æ d. The dollar weighs 17 dwt. 8 gr.; its fineness 8 dwt. worse than English standard; hence its value in English silver coin is 4½ 3½ d. See PISTOLE.

The value of reals of Spain, and monies of account, ex-

pressed in pence and decimals of pence, according to the mint price both of gold and silver in England, i.e. 3½ 17½ 10½ d. per ounce for gold, and 5½ 2 d. per ounce for silver, is as follows:

For the assay, weight, value, &c. of gold coins, see PISTOLE.

REAL or Real, is also a money of account at Leghorn. At Zante, and also Cefalonia and Corfu, accounts are kept in reals, of 10 lire, or 100 foldi, also called afpi. REAL is the name of a kind of boat in some places. REAL, or NOVIITA, in Geography. See NOVIITA. REAL Nuevo, a town of Mexico, in the province of New Biscay; 120 miles N.W. of Parral. N. lat. 29° 10', W. long. 107° 20'.
REAL del Reforio, a town of Mexico, in the province of Chiametlan, on the Spirito Santo; 24 miles N. of Chianmetlan.

REAL de Frayles, a town of New Mexico, in the province of Mayo; 60 miles from Santa Cruz. N. lat. 27° 44'. W. long. 110° 22'.

REAL de Minas, a town of New Navarre; 180 miles S.S.E. of Cafa Grande.

REAL de St. Juan, a town of New Navarre; 195 miles S.S.E. of Cafa Grande.

REAL de la Juera, El, a town of Spain, in the province of Seville; 25 miles N.W. of Carmona.

REAL, Knights of the, or Knights of the Lion, owed their institution to the following event. Ladislaus, son of Charles Duras, having been proclaimed and crowned king of Naples at Geta, the Neapolitans set up Lewis II., Duke of Anjou, and laid the foundation of the bloody wars that followed. These troubles divided the Neapolitan nobles into two factions; and of those who declared for the house of Anjou, some were on their left arm a golden real embroidered or on a red ground, by way of contempt to queen Margaret, widow of Charles III., who wanted to hold the reins of government during the minority of Ladislaus, and called themselves "knights of the Real." While others wore on their breast the figure of a "lion," with her feet tied," pendant to a ribbon which passed round their necks, indicating by it, that they looked upon queen Margaret as tied by the leg; and then styled themselves "knights of the Lion."'

REALJO, in Geography, a town of Mexico, in the province of Nicaragua, situated on a bay of the Pacific ocean, at the mouth of a river, both of the same name. The river is so deep and capacious as to be capable of receiving 200 fall of ships. The town is defended by large intrenchments, and very fine docks for building and repairing ships; but the place suffered considerably from the Buccaneers. The town is large, has three churches, and an hospital; but the place is unhealthy, on account of the creeks and flinking swamps in its vicinity. Its chief trade consists in pitch, tar, and codrige. At the mouth of the harbour is an island, which intercepts the sea, and renders it safe and commodious; it forms two channels, but that on the N.W. side is much the best; 18 miles N.W. of Leon. N. lat. 12° 45'. W. long. 87° 30'.

REALGAR, in Mineralogy, sometimes called red orpiment, an ore of arsenic, confiding, according to Thenard, of 75 parts arsene, 25 sulphur.

The colour of realgar is a bright deep red, palling into scarlet and orange; it occurs both massive, and crystallized in prisms, which have either 4, 6, 8, 10, or 12 sides, terminated by four-fided hunmists. The primitive form of the crystal is an octahedron, with faceted triangles. The lattice of realgar is between vitreous and waxy; it is semi-pellucid, soft, fragile, and easily fusable, burning in the air with a blue flame, and giving out arsenical and sulphureous vapours. By friction it becomes negatively electrical. Realgar is found in the vicinity of volcanos, and accompanying other metallic ores, both in primitive and secondary mountains. This substance is used as a pigment; and is formed by the Chineese into toys. See Sulphurated Arsenic under Arsene.

In the history of the French Academy, we have an account of a cup brought to Paris by the ambassadors of Siam, and presented there, as a remedy used by that people against all diseases.

REAL. Upon an examination, which had like to have coil M. Homberg dear, he found it to be a kind of realgar, or red arsenic, much more caustic than ours.

Its use among the Siamee, he takes to have been the same with that of regulars of antimony; viz. to give an emetic quality to the wine drank out of it.

As the dose of medicines is much stronger in the torrid zone than among us (the quantity of ipecacuanha, e. gr. ordinarily taken by the Indians, being twenty times as great as that among us), it is very possible a cup of realgar, though enough to poison an European, may prove a gentle medicine to a Siamee.

REALIS, REALISTE, a sect of school-philosophers who followed the doctrine of Aristotle with respect to universal ideas, formed in opposition to the Nominalists, (see that article,) who embraced the hypothesis of Zeno and the Stoics upon that perplexed and intricate subject.

Aristotle held, against Plato, that, previous to, and independent on, matter, there were no universal ideas or essences, and that the essences or exemplars which the latter supposed to have existed in the divine Mind, and to have been the models of all created things, had been eternally impressed upon matter, and were coeval with, and inherent in, their objects. Zeno and his followers, departing both from the Platonic and Aristotelian systems, maintained, that the pretended universals had neither form nor essence, and were no more than mere terms and nominal representations of their particular objects.

Under the Realists are included the Scotists, Thomists, and all excepting the followers of Occam.

Their distinguishing tenet is, that universals are realities, and have an actual existence, out of an idea and an imagination; or, as they express it in the school-language, a parte rei; whereas the Nominalists contend, that they exist only in the mind, and are only ideas, or manners of conceiving things.

Doctor Odo, or Oudard, a native of Orleans, afterwards abbot of St. Martin de Tournay, was the chief of the sect of the Realists. He wrote three books of dialectics; where, on the principles of Boethius and the ancients, he maintained that the object of that art is things, not words; whence the sect took its name and name.

REALITY, REALITAS, in the Schools, a diminutive of re, thing, first used by the Scotists to denote a thing which must exist of itself, or which has a full and absolute being of itself, and is not considered as a part of any other. Yet a reality is conceived as something less than re, and accordingly every re is supposed to contain a number of realities, which they otherwise call formales.

Thus, c. gr. in a man, according to the doctrine of the Scotists, are a number of realities; viz. a subsistence, life, animal, and reason.

Some
Some distinguishing reality into subjective and objective.

REALM, REGNUM, Kingdom, a country which gives its head or governor the denomination of king.

The word is formed of the French royaime, which denotes the same.

REALMONT, in Geography, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Alby; 9 miles S. of Alby. The place contains 2247, and the canton 8040 inhabitants, on a territory of 2471,000,000 square feet, or 19 communes.

REALVILLE, a town of France, in the department of the Lot; 8 miles N.E. of Montauban. N. lat. 44° 6'. E. long. 1° 34'.

REAMLA, a town of the Arabian Irak; 10 miles W. of Ballora.

REAMO, a town of Naples, in Abruzzo Ultra; 6 miles W.N.W. of Teramo.

REAMUR, a town of France, in the department of the Vendée; 18 miles N. of Fontenay le Comte.

REANG, a town of Bengal; 45 miles S. of Silhet.

REAPER, a person whose business it is to reap or cut grain.

REAPING, the operation of cutting crops by means of the scythe. It is a very laborious sort of field-work, and one which requires considerable attention and care to perform it in a neat and exact manner. Reaping is performed with some other sorts of crops, besides those of the grain kinds; as occasionally for peas, beans, flax, and others of a similar nature. Work of this nature is executed in many different ways, according to the customs of different districts; as by fets of men hired by the month, for this particular purpose, called harvet-men; by per sons cutting it by the piece, or by the acre, and by the sheaf or fack of eight sheaves.

In some methods, by the piece or the quantity is unquestionably the belt, in most cases, on account of the very high prices which are exacted at this very busy season, and the very small extent of labor which is performed in working by the day, which cannot be controlled by the farmer at such hurrying times. Besides, the work is, for the most part, the belt and most expeditiously performed in these ways; which are objects of very great importance, and deserving of much consideration in this sort of business. The eye of the farmer is, however, constantly necessary to see that all goes on in a right manner.

In the northern parts of Lancashire, this sort of labor is mostly performed by the day, or the bath of ten sheaves, of the ask or of twelve sheaves; three-pence being often paid for the former, and four-pence or five-pence for the latter, in these places.

In some districts, the reaping of the crops commences before they are quite ripe; but in others, not until this has fully taken place.

REAPING of Corn, the practice of cutting it with the scythe, or otherwise, by persons employed for the purpose. It may be observed, that the business of reaping or cutting grain crops differs much in the manner of performing the work, in different districts of the kingdom, and kinds of crops. In the more southern parts of the island, the crops of this sort are mostly cut by means of short flit fickles, made for the purpose, having bows formed of bent fickles, or what in some places are termed cradles, fixed upon the lower part of the handles, for the more readily depositing the ears or heads of the corn in one uniform direction, as much as possible, in order that it may be afterwards bound up into sheaves. But in other cases, the naked fcythe is made use of; the corn being seldom bound up, being simply raked together into small heaps, in a similar manner to hay.

In the more northern parts of England, and in Scotland, the reaping of grain crops is, however, in general performed by the scythe, or reaping hook; the different handfuls, as soon as cut, being deposited upon bands, formed by twitling together a few stalks of the corn at the ends next the ears, and afterwards bound up into sheaves, in order to their being set up into jacks or battocks. This method is, in most instances, adopted with the wheat and rye crops, in every part of the island; as in cutting them with the fcythe, it is difficult to be performed without much loss being sustained by the sheathing of the grain. And, in addition, it is of great advantage to have these sorts of crops bound up regularly into sheaves, the fraw being much better.

Besides these, there is another mode sometimes practised, which is by means of a hook with a sharp edge, without any teeth; the labourer, in executing the work, catching up the corn towards him. It is mostly made use of in the southern districts, where it is known by the name of bagging, the grain in this way being cut very low.

In this way the reaper collects enough for one sheaf at a time, binds it, and sets it up in tens, called a fack in Middlesex. This bagging (or facking) practice is, to all intents and purposes, mowing with one hand against the standing corn. The toothless hook, employed in doing it, is of nearly twice the weight of the common fcythe. It is sharpened occasionally, when necessary, in the manner of the fcythe; and the operation of cutting the corn down is by a succession of blows made upon the fraw of the standing corn, very nearly in the direction down towards the surface of the ground. Reaping in Middlesex is mostly all done in this way, as the proper use of the fcythe is but little known.

This method has the advantage of being done cloher, and with equal or more expedition than the hand-reaping mode, besides the saving in fraw, which is here supposed worth 7s. the acre.

In Essex wheat crops are generally reaped or cut with the scythe, though in the vicinity of the metropolis it is not uncommon to have it mown with the fcythe, as close to the ground as other sorts of grain crops, in the view of increasing the quantity of fraw, which is there very valuable. It is thrown, in these cases, with great skill and dexterity into swaths. When perfectly ripe, it is soon bound up into sheaves of six or eight inches diameter, with bands of wheat-fraw of single or double lengths; but when not in this ripe or dry state, it is allowed to remain in the swaths two or three days, as necessary. However, in more than three quarters of the county, it is reaped or cut with the fcythe; and indeed in almost all places, when beaten down by the wind and rain.

In regard to the time of reaping the grain, there is considerable difference in different districts; some not reaping it until it is quite ripe, while others cut it when something short of this fstate. This, however, should probably be regulated by the nature of the season, and the kind flate or quality of the crop, as well as the use to which the grain is to be put.

In respect to the manner of reaping grain crops, whether the fcythe or fcythe be employed for the purpose, there is much difference in the height at which the crops are cut in different places. In some it is the practice to have the fcythes performed in as close a manner as possible; while in others a fumble of eight, ten, and fifteen inches; or more,
is left. These different practices have their advocates; one party supposing that the work proceeds more slowly, where it is executed in so close a manner; while the other contend that the contrary is the case. But as the flubble which is left is not only useless to the land, but in many cases very troublesome in its succeeding culture, being frequently under the necessity of being removed, it would seem to be the best as well as cheapest practice, to have the businesfs constantly executed in a close manner. It has been observed by a late practical writer, that by this means the agriculturist will not only have more litter at command, for the bedding of his yards, stack, and other places, and consequently an increase of manure, but have the businesfs more expeditiously performed, with much less waste of grain, and at the same time be freed from the trouble and expense of removing the flubble. It has indeed been fully flown, by a careful trial, made with the view of ascertaining the difference between high and low reaping, that the advantage is considerably in favour of the close method.

And the result of the trial is thus stated by the writer of the Agricultural Survey of the West Riding of Yorkshire, who observes that the experiment was made upon part of a field of wheat, two ridges of which were cut close by the ground, and the other two considerably higher, though not so high as the general run of the Yorkshire flubbles. Each of the divisions was apparently of equal quality, and measured a trifle more than a quarter of a Scotch acre, which is about one-fifth larger than the English statute acre. The crop was flacked separately, and the time taken to part cut low was one hour and twenty-four minutes, of eight hearers; while the high cutting was performed by the same number of hands in forty-eight minutes. The wages paid that week were 18d. per day, and the supposition of maintenance 5d. or 2s. per day altogether. When threshed, the grain and straw were carefully measured and weighed, and the result of the experiment was as follows:

<table>
<thead>
<tr>
<th>Description</th>
<th>Quantity</th>
<th>Cost per acre</th>
</tr>
</thead>
<tbody>
<tr>
<td>Result - 8 hearers, 1 hour 24 minutes, at 2s.</td>
<td>£  2 4</td>
<td></td>
</tr>
<tr>
<td>per day, or 22½d. per hour</td>
<td>2 4</td>
<td></td>
</tr>
<tr>
<td>The same hands in 48 minutes</td>
<td>0 1 4</td>

</tr>
<tr>
<td>Difference of expense</td>
<td>0 1 0</td>
<td></td>
</tr>
</tbody>
</table>

In favour of high cutting one shilling, or four shillings per acre.

1½ peck of wheat more upon the low cut ridges than those cut high, at 1s. 4d. per peck | £  1 8 |
14 stones (22 avoirdupois pounds) of more straw, at 2d. per stone | 0 2 4 |

Or sixteen shillings per Scotch acre.

From which deduct the increased expense of cutting, there remains a benefit of twelve shillings per acre in favour of low cutting.

It is noticed farther, that the above trial, according to the belief of the reporter's judgment, was fairly made; and the reason which urged him to make it, was to silence the objections of some neighbours, who alleged low hearing was not profitable. It is also proper to observe, that the field of wheat, on which the trial was made, was not broke down nor itraggled, so was in a favourable condition for high cutting. We have seen wheat-fields, where three times the quantity might have been left, unless great pains were used.

But the methods of reaping grain crops, both with the fickle and the scythe, have each their advantages and disadvantages. In the first manner, the crops are depreciated with more regularity and exactness, and consequently bound into sheaves with greater facility and dispatch. Besides, in many cases, the loss of is incurred by shedding, in the time the work is in performing; but the labour is executed with greater difficulty and trouble. The latter poiflhes the superiority of being more expeditious, and of being performed to any degree of cloveness that may be required; while it has the evident disadvantage of leaving the cut grain in a more irregular and uneven situation, by which it is rendered fit for being bound up into sheaves, which in many cases is an inconvenience of great consequence. When the grain has attained a high degree of ripeness, there may likewise be great loss sustained, by its being left during the operation, in this way of reaping and cutting the crop. Where this method is practised, it is, however, not unfrequently the case to have it bound into sheaves; though the most common custom is to let it remain in the rows or swathes, till fit for being put into the stack. When bound, it is generally the practice to cut it inwards against the crop on which it rests: in the other case, it is cut in the manner of grafs for hay. It is obvious, therefore, that when labourers are procured with difficulty, this mode of reaping is the most advisable; while, under the contrary circumstances, the former may be had recourse to with more advantage, as the work may be executed in a neater and more exact way. See Harvesting and Sickle.

It may be remarked, that this is a sort of work that is often let by the acre to persons that go about for harvest work; and it may, in many cases, be the belt performed in this manner. But great attention should be paid by the farmer, to see that the grain is cut and bound up in a proper method, and that the work be not performed in improper weather. The prices vary according to the nature of the crops, the season, and other circumstances, sometimes rising as high as eleven or twelve shillings the acre, and sometimes much higher.

Reaping Fork, a tool of the fork kind, invented for the purpose of raising and collecting the mown grain into sheaves, so that it may be bound up. It is constructed with two, rather long, prongs below, slightly curving upward, somewhat in the manner of the common large hay fork, to which are attached, at the upper part, near the insertion into the handle, two other upright prongs, which bend a little forward towards their tops or ends; by means of which, with the under prongs running along the ground, the tool being pushed forward by the labourer, the grain in the straw is raised up, brought together, held in a firm manner, and removed from the swathe so as to be bound into sheaves. In this way, the lower prongs perform the work of picking the strawy material from the land, while the higher upright ones prevent it from falling backwards, and determine the quantity which is necessary for a sheaf. In this manner, by this simple contrivance, the mown grain can be brought together and bound up with much greater regularity, and in a much more expeditious method than is possible to be done by mere hand labour.

Reaping Hook, an implement of the fickle kind, with which the businesfs of reaping is performed in some districts. These hooks are sometimes formed with teeth, or in a toothed manner, and sometimes with a cutting edge. In Devonshire, and some other counties, these with smooth edges are generally preferred to fickles with sawed ones;
these sorts of hooks are used occasionally with either hand, the operator shifting hands, chopping the straw low down, and gathering about half a sheaf at a time, which, when put together, is bound with reed, combed from former wheat-straw, or with a double length of the wheat which is reaping. See Sickle.

Reaping Machine, a contrivance for the purpose of reaping grain by means of animal labour. With this view, and to facilitate an operation of such importance to the farmer, different attempts have been made to construct machines, so as to dispatch the work in a rapid manner by the afflance of horse labour, but the success with which they have been attended, has hitherto been far from complete. An implement of this sort has lately been made by Mr. Plunkett; it is upon a somewhat new principle, the horse drawing the machine instead of pulling it forward, as was the old mode of applying the power.

In this machine, the horse tracks from the front side of it, which is seen at once by the appearance of the implement, so as to be clear of the crop, and the two large wheels, by means of the axle, drive another wheel, which communicates with the two other wheels, the latter of which is found in the axis of the cutter: a man at the handles regulates the direction, &c. This machine may be seen fully represented in the second volume of the Farmer's Dictionary; and a reaping machine for clover may be seen in the same work in the same plate.

Other machines of this kind have still more lately been invented by other persons, but without answering the purpose in that full and complete manner which is necessary in this sort of work.

What appears to be chiefly wanting in these sorts of machines, to render them complete and effectual, as tools for the purpose of reaping, is that of their having more power or velocity in the cutting parts, so that the work may be performed in a perfectly clean neat manner, without the straw being drove or forced down in an improper manner before the instruments which are to cut it; their cutting it out fully in the whole of its breadth; their being capable of being regulated to cut at different heights, and to different breadths; their being made capable of directing the cut strawy grain all in one even regular direction, so that it may be bound up with facility; the horses, or other animals, being so attached to them as to permit of their walking along on the side of the standing grain, where the former cut was made, or where they pull the implements before them, the having them so conveniently fixed in them as to admit of no sort of interruption to the labour in any way; their being made light and of ready application, as well as at a cheap rate; and their keeping the field or cutting parts in a perfectly sharp state, without their being made out, and undergoing the operation of whetting. There are, besides these, some other points, which should be attended to, but these are, probably, the most material.

Reaps, small parcels of corn, laid along on the stubble, in reaping, to be afterwards gathered into sheaves by the binder. This is most commonly the cafe, when the weather is moist, as in dry times the reaps of corn are usually laid in the bands, and tied up, as soon as they are in sufficient quantity, into sheaves.

Rear, a term frequently used in composition, to denote something behind or backward in respect of another; in opposition to van, or avant, before.

It is formed by corruption of the French arriere, signifying the same.

Rear, in a Military Sense, is used for the hind-part of an army, &c. in opposition to the front, or face of it.

Rear, in Naval Language, is a name given to the last division of a squadron, or the last squadron of a fleet, and which is accordingly commanded by a rear-admiral, or the third officer of the said fleet or squadron.

Rear-admiral. See Admiral.

Rear-guard. See Guard.

Rear-half-staffs, are the three hindmost ranks of a battalion, when it is drawn up fix deep. See File-leaders.

Rear-line of an army encamped, is always twelve hundred feet at least from the centre line, both of which run parallel to the front line, and allow to the referee.

Rear-rank, is the last rank of a battalion, or squadron, when drawn up, and generally sixteen or eighteen feet from the centre line, when drawn up in open order.

Rear-squadron, in the Manege, called a French cabal, is the action of a horse, when he raises himself upon his houghs or hinder legs, as if he would fall quite over in a backward direction, to the great danger of his rider. This is often caused by his having too much of the curb.

Rear, in Rural Economy, to raise the roof part of any fort of shed or other building for containing some kind of live-stock.

Rear, or Well-rear. See Wale-reared.

Rearing Animals, in Agriculture and Rural Economy, the busines of breeding and bringing them up to the most suitable flates for the purposes of the farmer. The principles of this art depend upon a variety of different circumstances and kinds of knowledge, as has been already explained. See Breeding, and Live-Stock.

Animals of the horse kind should invariably be brought up in the best manner, without any sort of flitting in their food, according to the ufe they are designed to serve, in order that they may have their full growth and power. In the labouring cattle kinds of animals, attention should, in some degree, be paid to hardiness, both in their food and their exposure, by having recourse to the more coarse sorts of feeding in the less sheltered situations, but nothing of flitting should ever be allowed, as by these means they become large, and capable of sustaining a greater degree of exertion. There is, likewise, much utility in good training, in rearing all sorts of animals in this intention; and it requires careful, steady, mild persons to be employed in it, as they, for the most part, acquire the habits and dispositions of those about them, in some measure; and the more early they are obtained the better. This point deserves much more attention from farmers and others than it has hitherto met with, as a great deal of the bad habits of working animals arise from the neglect of it. Besides, good training and mild dispositions are highly favourable to fattening animals. See Horse.

In rearing poultry, pigeons, rabbits, and fish, much care, management, and circumpection, are constantly necessary, in order to their perfect success. Too little attention is for the most part bestowed on the nature of the birds, in some sorts of the more wild poultry kinds, as those which are of the game description, for instance, the galena, the pheasant, the swan, and some others. These cannot be so readily reared, or so much facilitated, under tents of the domestic kind, as other sorts are, such as the turkey, peacock, &c. This circumstance should therefore be always kept in mind in rearing such birds. See Poultry, Pigeons, Rabbit, &c.

A very nice attention and management is also requisite in the rearing and perfecting of fish. See Fish, Pond-Fisheries, and Salmon Fishery.

In rearing birds of the game kind, such as the above, in the way of ornament about a residence, Mr. Loudon has remarked, much depends upon encouraging them, when al-
allowed to go wild, by giving them proper and abundant cover, and bowing among it such herbs and plants as they are particularly fond of, as those of the crefs, chervil, parsley, thyme, and some other kinds. They have likewise a tendency to encourage and domesticate hares. Abundance of fearles game about a residence, he thinks, give a peculiar nobleness, and appearance of freedom, which few things else can communicate or afford.

REASON, RATIO, a faculty or power of the soul, by which it distinguishes good from evil, and truth from falsehood. Or, reason is that principle, by which, comparing several ideas together, we draw consequences from the relations they are found to have.

Some of the later school-philosophers define reason to be the comprehension of many principles which the mind successively can conceive and from which conclusions may be drawn.

Others conceive reason as no other than the understanding itself, considered as it discourses.

Reason, Mr. Locke observes, comprehends two distinct faculties of the mind; viz., faculty, by which it finds intermediate ideas; and illusion, by which it discovers and distinguishes them, to discover what connection there is in each link of the chain, by which the extremes are held together; and by them, as it were, draws into view the truth sought for.

Illation, or inference, consists in nothing but the perception of the connection there is between the ideas in each step of the deduction, by which the mind comes to see either the certain agreement or disagreement of any two ideas; as in demonstration, in which it arrives at knowledge; or their probable connection, on which it gives or withholds its assent; as in opinion.

Sense and intuition reach but a little way; the greatest part of our knowledge depends upon deductions, and intermediate ideas. In those cases, where we must take propositions for true, without being certain of their being so, we have need to find out, examine, and compare, the grounds of their probability; in both cases, the faculty which finds out the means, and rightly applies them to discover certainty in the one, and probability in the other, is that which we call reason.

In reason, therefore, we may consider four degrees; first, the discovering and finding out of proofs. See Invention.

Secondly, the regular and methodical disposition of them, and laying them in such order, as that their connection may be clearly perceived. See Method.

Thirdly, the perceiving of their connection (See Judgment.) And,

Fourthly, the making a right conclusion. Reason fails us in several instances; as, first, where our ideas fail.

Secondly, it is often at a loss, because of the obscurity, confusion, or imperfection, of the ideas it is employed about. Thus, having no perfect idea of the least extension of matter, nor of infinity, we are at a loss about the divisibility of matter.

Thirdly, our reason is often at a stand, because it perceives not those ideas which would serve to shew the certain or probable agreement or disagreement of any two other ideas.

Fourthly, our reason is often engaged in absurdities and difficulties, by proceeding upon fallacious principles, which, being followed, lead men into contradictions to themselves, and incongruity in their own thoughts.

Fifthly, dubious words, and uncertain sign, often puzzle men's reason, and bring them to a point.

Though the deducing one proposition from another be a great part of the office of reason, and that about which it is usually employed; yet the principal act of reasoning is the finding the agreement or disagreement of two ideas; one with another, by the intervention of a third. As, a man, by a yard, finds two bowers to be of the same length, which could not be brought together to measure their equality by juxtaposition. Words have their consequences as the signs of such ideas and things agree or disagree with what they really are; but we observe it only by our ideas.

Hence we may be able to form an idea of that ordinary dilution of things, into such as are according to, those that are above, and those contrary to reason.

Those according to reason are such propositions, whose truth we can discover by examining and tracing those ideas we have from sensation and reflection, and by natural deduction find to be true or probable.

Those above reason are such propositions, whose truth or probability we cannot by reason derive from those principles.

Those contrary to reason are such propositions as are inconsistent with, or irreconcilable to, our clear and distinct ideas.

Thus the existence of one God, is according to reason; the existence of more than one God, is contrary to reason; and the resurrection of the body after death, above reason.

Above reason may be also taken in a double sense; viz. above probability or above certainty.

They who dispute most about the power and privileges of human reason, do it because their own reason persuades them to that belief; and so, whether the victory be on their or our side, they are equally defeated.

They seek to terrify us with the example of many great wits, who, by following this ignis fatius (so they call the only pole-star God has given us to direct our course by), have fallen into wild and ridiculous opinions, and increased the catalogue of heresies to far greater a number; but these men either followed not their reason, but made it follow their will; or else they first hoodwinked it by interest and prejudice, and then bade it shew them the way; or were wanting in those necessary diligences required for it, doubtless a part of us; or if, without any of these, the weakness of their understanding had deceived them, the error is neither hurtful to themselves, nor would be to others, if this doctrine of governing ourselves by our own reason, and not by authority and example, were generally established. Dis. Concern. Hum. Reason.

It is not the use of such liberty, but the appropriating it to ourselves, that is the cause of all the disorders charged upon it; for those who lay a restraint on other men's reason, have first made use of their own to settle them, and to make use of it in this very restraining of others. Ibid.

REASON, in Matters of Religion, is used in opposition to faith.

This use of the word, Mr. Locke takes to be in itself very improper; for faith is nothing but a firm assent of the mind; which, if it be regulated, as it is our duty, cannot be afforded to anything but upon good reason, and so cannot be opposite to it.

He that believes without having any reason for believing, may be in love with his own fancies; but he neither seeks truth as he ought, nor pays the proper obedience due to his Maker, who would have us use those differing faculties, he has given him, to keep him out of mistake and error.
R E A

But since reason and faith are by some men opposed to one another, it may be necessary to consider them together.

Reason, as contradistinguished to faith, is the discovery of the certainty or probability of such propositions, or truths, which it has got by the use of its natural faculties; viz. by sensation, or reflection.

Faith, on the other hand, is the assent to any proposition upon the credit of the proposer, as coming immediately from God; which we call revelation, which see.

Reason, in Logic and Rhetoric, denotes a necessary or probable argument; or an answer to the question, cur est? why is it?

As if it be inquired, why do the subject and predicate agree? and it is answered, because they are spoken of the same thing; this last enunciation is a reason. Hence, say the schoolmen, because quia is the sign or character of a reason, as non, no, of a negation, and est, is, of an affirmation.

They make three kinds of reasons, ratios; viz. ratio ut, that is, est, let; and quia, because. For, answering to a question, cur est? why is it? and quia, because, we begin with because, quia; as, why do you think? that I may become learned; which is the ratio ut.

Again, why do you judge? I should be ignorant: which is the ratio non. Lastly, why is a body tangible? because matter is impenetrable; which is the ratio quia.

The reason ut properly denotes the end, or final cause; and reason non the beginning; accordingly the one is called the beginning, the other end; so that the reason quia is left the only reason, properly so called.

Reason, among Metaphysicians, is used in the same sense with evidence; or that by which anything is what it is.

This is sometimes also called formal reason, as representing the thing under that form or nature under which it is conceived.

Reason, in Mathematics. See Ratio.

Reason of State, Ratio Status, in Matters of Policy, denotes a rule or maxim, whether it be good or evil, which may be of service or service to the state. The phrase is borrowed from the Italians, who first used risone del stato in this sense.

Reason of state is properly understood of something that is necessary and expedient for the interest of the government, but contrary to moral honesty, or justice.

Politicians have a long time disputed about the ratio status; whether states and governments are tied down to the same laws of morality with individual persons; or whether things, otherwise immoral and unlawful, may not be practised on urgent occasions, by way of reason of state?

The question is, whether any thing be unlawful, or prohibited a state, that is necessary to the preservation of that state, or whether it be allowed to preserve itself on any terms?

Reason sufficient of Leibnitz. See Leibnitzian Philosophy.

Reasonable Aid, a duty which the lord of the fee anciently claimed of his tenants, holding in knight's service, or on socage, towards the marrying his daughter, or the making his eldest son knight.

This is taken away by stat. 2 Car. II. See Aid.

Reasoning, Ratiocination, the exercise of that faculty of the mind called reason: or, it is reason deduced into discourse; which see.

The agreement or disagreement of two ideas does not appear from the bare consideration of the ideas themselves, unless some third be called in, and compared, either separately, or conjointly with it: the act, then, by which, from ideas thus deduced and compared, we judge this or that to be so, or not so, is called reasoning. Or, it is that operation of the mind, by which we infer one thing, i.e. one proposition from two or more propositions premised. Or, again, it is the drawing of a conclusion, which before was either unknown, or dark, or doubtful, from some propositions which are more known and evident. It is the narrow-ness of the human mind which introduces the necessity of reasoning; for if the mere perception and comparison of two ideas would always show us whether they agree or disagree, then all rational propositions would be matters of intelligence, or first principles, and there would be no use of reasoning, or drawing any consequences. But when we are unable to judge of the truth or falsehood of a proposition in an immediate manner, by the mere contemplation of its subject and predicate, we are thus constrained to use a medium, and to compare each of them with some third idea, that by seeing how far they agree or disagree with it, we may be able to judge how far they agree or disagree among themselves. Watt's Logic, part iii. chap. 1.

Rohault defines reasoning to be a judgment depending on some antecedent judgment: thus, having judged that no even number can be composed of five uneven numbers, and that ten is an even number; to conclude, that ten cannot be divided into five uneven parts, is a ratiocination, or reasoning.

This agrees with father Malebranche's doctrine, one of the great points of which is, that reasoning, on the part of the understanding, is only a mere perceiving.

That ingenious author endeavours to shew, that, as to the understanding, there is no difference between a simple perception, a judgment, and a reasoning, except in this, that the understanding perceives a simple thing without any relation to any thing else, by a simple perception; that it perceives the relations between two or more things in a judgment; and, lastly, that it perceives the relations that are between the relations of things, in a reasoning. So that all the operations of the understanding are no more than mere perceptions.

Thus, c. 87. when we conclude, that 4 being less than 6, twice 2 being equal to 4, are of consequence less than 6, we do no more than perceive the relation of the inequality between the relation of twice 2 and 4, and the relation of 4 and 6.

The manner of proceeding judiciously in reasoning; so as to arrive with the greater safety at the knowledge of truth, makes what we call method.

For the real benefit of logic to reasoning, see Logic and Syllogism.

RE-ATTACHMENT, in Law, a second attachment of him who was formerly attached, and dismissed the court without day, by not coming of the justices, or the like casuistry.

Brook makes re-attachment either general or special. General is where a man is re-attached for his appearance on all writs of affize lying against him; special, for one or more certain writs.

REAU, in Geography, a town of Germany, in the principality of Calmbach; 5 miles S.E. of Hof.

REAVE, in Rural Economy, a provincial term, used to signify the unrooking or disturbing the thatch or other covering of a building by winds, &c.

REAUHUR, REINE-ANNEE FERCHAULT, SIEUR DE, in Biography, was born in 1805 at Rochelle. He was brought up to the study of the law, which he quitted for that
that of the mathematics, natural history, and natural philosophy. In 1703 he went to Paris, and so distinguished himself in a few years, that in 1708 he was admitted into the Academy of Sciences. From that time he entirely gave himself up to the pursuits of natural history in all its branches, and few men have professed a life more actively and usefully employed. Utility was the constant aim in all his enquiries, even into the most minute parts of nature; and experiment and observation were his perpetual guides. No one surpassed him in the patient industry with which he observed natural phenomena, or followed the procedures of art. The Memoirs of the Academy of Sciences, from 1729 to 1756, are enriched with his communications. The improvement of manufactures was a great object of his attention. In 1722 he published a work, entitled "L'Art de convenir le Fer forge a Acier, et l'Art d'adoucir le Fer fondu," which contained a minute and scientific account of the processes employed in that branch of manufacture, with hints for their improvement. He introduced into France the manufacture of wrought iron, which article had before been imported from abroad; and he made a great many experiments in the manufacture of porcelain, which contributed to its perfection in France. He also performed numerous experiments relative to the art of hatching chickens by artificial heat, as practised in Egypt, an account of which he published in two vols. 1752. M. Réaumur rendered his name celebrated by his peculiar method of graduation on the thermometer, which is still the only one used in France and many parts of the continent. In this thermometer the freezing point is marked zero, and the boiling point at 80°. (See Thermometer.) Some of the most valuable of Réaumur's physiological experiments were those relating to the concussive powers of the flomach in granivorous and carnivorous birds, in which he clearly establishes the different modes of action in these two classes, v. e. by trituration, and by solution. In natural history, he acquired the greatest fame as an entomologist. Besides a number of curious papers on this subject in the Memoirs of the Academy, he published a very elaborate work, entitled "Memoires pour servir a Histoire Naturelle des Insectes," in six vols. 4to. 1734—1742. This work was the labour of many years, and the result of innumerable observations made in his garden, in which he kept insects of all kinds, that he might examine their generation, changes, and mode of life. Réaumur was a man of much private worth, of mild and amiable manners, and correct morals. He died in 1757; at the age of 75. He bequeathed his manuscripts, and cabinet of natural philosophy, to the Academy of Sciences.

REAUMURIA, in Botany, so called in honour of the great French naturalist, René Antoine Ferchault de Réaumur, principally known as a botanist, by his examination of the freezing of Fer, but chiefly celebrated as a philosophical inquirer into the history of insects, and their transformations, to which the specific name of the original species, vermiculata, evidently alludes. Linnaeus mentions Haefleqaut as the author of the name Reaumuria; of which we can find no traces in his book, though the specimen of the plant in the Linnean herbarium, has some appearance of having been gathered by this distinguished Oriental traveller. It is possible, that the Anonymous dubii, n. 15, of his Iter Palestinem, 405, which his editor Linnaeus could not make out, can be the Reaumuria. The description is not inapplicable, except what concerns the flomens and style. Yet this does not make him the author of the name, though it may possibly account for Linnaeus's mention of him in conjunction therewith. The latter appears, by his manuscripts, to have once defined Veremcularis for the generic appellation.—Linn. Gen. 276. Schreb. 371. Wild. Sp. Pl. v. 2. 1249. Mart. Mill. Dict. v. 4. Alit. Hort. Kew. v. 3. 527. Jull. 316. Lamarck Illust. t. 489. Dict. v. 6. 84. —Chas and order, Polyandria Pentagynia. Nat. Ord. Succulentes, Linn. Ficoides, Jull. Gen. Ch. Cal. Perianth inferior, of five prominent, ovate, pointed, permanent leaves. Cor. Petals five, oblong, equal, stellate, rather longer than the calyx, oblique, or lobed, at the extremity. Nectary of five double, fringed scales, at the meeting of the petals, attached to their lower part. Stam. Filaments numerous, capillary, the length of the calyx, inserted into the receptacle; Desfont. anthers roundish, incumbent. Pet. German superior, roundish; stigmas flat, anther, flat, oblong, entire, clothed with numerous, filky, simple hairs, twice their own length. Ep. Calyx of five leaves. Petals five, with ten fringed scales at their base. Capsule of five cells, with five flat, at length reflexed, valves; the partitions membranous, unconnected, deciduous. Seeds several, erect, oblong, entirely clothed with numerous, filky, simple hairs, twice their own length.

1. R. vermiculata. Saltwort-leaved Reaumuria. Linn. Sp. Pl. 754. Wild. n. 1. Forsk. Egypt. Arab. 101. Desfont. Atlant. v. i. 431. Lamarck Illust. t. 489. f. 1. (Sedum ficulum maritimum vermiculatum, flore Saxifragae albae, femine villiolo Boe. Sic. t. 4. f. C. G. S. minimum arborecens vermiculatum; Lob. 1c. 380. Kali vermiculatum albo et amplo fedi rofis flore; Barcel. t. 888. Veremcularia frutex minor; Ger. Em. 523; at last the figure, which is that of Lobel. The description accords rather with Saltola fruticoso, as cited by Hadon.) —Leaves linear-awl-shaped, convex beneath. Calyx entire. —Native of barren sandy ground towards the sea, in Sicily, Barbary, Egypt, and Syria, flowering in summer. The habit of the plant is like a Tamarisk, or Saltola. Stems shrubby, bushy, much branched, round, smooth, whitish, leafy. Leaves several, scattered, stellate, from a quarter to three quarters of an inch long, spreading, linear-awl-shaped, acute, fleshy, smooth, glaucous; convex beneath; flat above; dotted on both sides with minute depressions. Desfontaines compares the leaves to those of Sedum reflexum. Flowers terminal, solitary, white, not unlike those of Saxifraga Cotyledon, each encompassed with a number of imitated floral leaves, like those of the item or branch, but longer. Calyx-leaves ovate, with a narrow, entire, membranous edge, and awl-shaped leaf-like point. Petals terminating in three flight lobes, well represented by Barcelier. Capulete brown, very smooth, and somewhat shining; its valves rigid, reflexed after the seeds are discharged, and permanent. Seeds clothed with long, tawny, shining hairs. Forskall says this plant is used at Alexandria as a curd for the itch, being applied bruised externally, and taken internally in the form of a decoction. It is an elegant little shrub, well worthy of a place in our gardens, or green-houses, to which it is as yet a stranger.

R E A

Parad. t. 18. Hypericum alternifolium; Labillard. Syr. falc. 2. 17. t. 12.)—Leaves elliptic-lanceolate, flat. Calyx minutely crenate.—Gathered in barren dry ground, near the defert of Syria, by M. Labillardiere, to whom we are obliged for a wild specimen. The plant is said to have been introduced into England, by the late Mr. John Bell, about 1800, and is marked by Mr. Aiton as a hardy perennal. Its true genus is well ascertained by Lamarck, Poiret, and Salisbury. The stem is herbaceous, about a foot high, simple, or branched, smooth, pale or reddish. Leaves alternate, glaucous, from half an inch to an inch in length, elliptic-oblong, or somewhat lanceolate, varying greatly in breadth, dotted all over. Flowers terminal, solitary, pale rose-coloured, with eblique petals. Calyx-leaves broader than in the former; their membranous edges finely crenate, their points very small. We know nothing of the capsule or seeds.

Reay, in Geography, a town of Scotland, in the county of Caithness; 6 miles W. of Thurso.

Rebach, a river of France, which runs into the Rhine, nearly opposite to Manheim.

Rebaïs, a town of France, in the department of the Seine and Marne, and chief place of a canton, in the district of Coulommiers; 7 miles S. E. of it. The place contains 1376, and the canton 11,284 inhabitants, on a territory of 190,000, in 18 communes.

Re-baptisants, a religious sect, who maintain, that perfons irregularly baptiz'd are to be baptiz'd afresh.

The Anabaptists are re-baptiz'd, inasmuch as they baptiz'd those at maturity, who had been before baptiz'd in childhood.

St. Cyprian and pope Stephen had mighty differences about the re-baptizal of converted heretics.

Donatus was condemned at Rome in a council, for having re-baptiz'd some perfons, who had fallen into idolatry after their first baptism.

Rebat, in Geography. See Rabat.

Rebate, in Architecture. See Joinery and Plane.

Rebate, or Rabat, Rebatement, in Commerce, a term much used at Amsterdam for a discount or abatement in the price of certain commodities, when the buyer advances the sum in hand, for which he might have taken time. See Discount.

Rebate (among us usually called prompt payment) is estimated by months, and is only allowed for certain kinds of merchandize, which, according to the custom of Amsterdam, are

15 months, or 10 per cent. on German, Prussian, and Polish wools.
18 months, or 10 per cent. on brown Muscovado sugar, pot-ashes, soda, Italian Armolines, fatin, damlak, and flax flufs.
21 months, or 14 per cent. on Spanish wool and lamb's wool.
22 months, or 22 per cent. on Italian silk and raw silk from the Levant, which flufs are fold by the Antwerp weight, about 5 per 100 lighter than that of Amsterdam.

Dutch cloths, camlets, &c. are fold with 4 per cent. rabat, for ready money, or without any rabat at 9 months' credit.

Dutch flufs are fold with 2 per cent. rabat at 6 months' credit: with 4 per cent. at 3 months; or with 6 per cent. for ready money.

In all fales of goods, except those last mentioned, a further abatement is made of 1 or 2 per cent. for prompt payment.

At Hamburgh, some forts of merchandize, when fold in large quantities, have an allowance made of 7, 12, or 19 months rabat, reckoned at 8 per cent. per annum; which the buyer, when he pays ready money, or pays within four weeks of the day of sale, deducts from the nominal price.

Refined fuggars, English and Dutch cloths, English baize, shalloons, flamels, kerfefermes, ratteens, and ferges, are fold with 7 months' rabat, or 42 per cent.; that is, 47 are deducted from 105, or 7 from 157.

Cotton, cinnamon, cochineal, indigo, ginger, nutmogs, cloves, mace, rice, raw fuggars, capers, currants, cumine, gall-nuts, Ruffian leather, linen, crape, Italian silks, table-linen, Sylfia cloth, Marfellies foap, almonds, fumac, mollasses, Turkish yarn, Italian tartar, are fold with 13 months' rabat, or 8½ per cent.; that is, 13 is deducted from 163.

Silks from the Levant, as Ardellef, Barutine, and Cerbali, are fold with 16 months' rabat, or 10½ per cent.; that is, 8 is deducted from 83. Kelly's Uni. Camb. vol. i.

This interest, called rebate, or rabat, is usually regulated on the footing of 8 per cent. per annum.

The reason of this expedient is, that the merchants having not always wherewithal to pay for their goods in hand, by means of the rebate, such as have, will find their account in it; and such as have not will be engaged to discharge themselves as soon as possible, for the sake of the discount.

Rebatement, in Heraldry, a diminution or abatement of the dignity of the figures or bearing in a coat of arms. See Abatement.

Rebebe, in Commerce, a measure of corn in Egypt, particularly at Alexandria, equal to about 45 bushels; as kifloz, another measure, is equal to 42 bushels, English measure: 17.94 rebbees are equal to 10 English quarters, and each of them contains 9587 cubic inches; and 16.51 kiflos are equal to 10 English quarters, and each contains 10418 cubic inches.

Rebec, a musical instrument resembling a fiddle, with a neck, finger-board, three strings tuned 5ths, and played with a bow.

Etymologists have tortured themselves to find a derivation for the name of a vulgar instrument, no longer in use. Some trace it from the Arabic, come from the Celtic, the Welsh, the Spanifh, Italian, and old French. Indeed, fo numerous, discordant, and unsatisfactory are their opinions, as neither to be worth writing, nor perusal, if we could give them a place.

Rebec and ribble seem to be the same instrument, and are often indiscriminately used by Gower, Chaucer, and the still more ancient bards of Normandy, and our own country.

As the head, or scroll-work, of old viol and violins used to be curiously carved, so seems to have been that of the rebec. Chaucer compares the face of an old woman, an old trot, to the head of a rebec. Rabelais does the same.

"A tel minetrier tel rebec
Tenant toujours le verre au bec
Car elle avoit vilage de rebec."

Rebecco, in Geography, a town of Italy, in the department of the Parma; 29 miles S.W. of Modena.

Rebel, Jean-Ferry, feën in Biography, one of the 24 violins of the king of France's band, and chamber com- poser to his majesty. He beat time for many years at the opera, and, in his day, pulled for a great composer. His music for dances is still heard with pleasure. His capriccios, freaks, and dancing characters, have enjoyed great reputation. In 1703 he let the opera of Ulysses, written by Guichard.
Rebel left two children: Francis, who died in 1775, and Anne, the wife of the celebrated Lalande, master of the king's band.

Rebel, François, knight of St. Michael, master, like his father, of the king's band, and director of the opera, born 1702, and died in 1775. He was the son of Jean-Ferry Rebel, director of the orchestra at the opera, and one of the twenty-four violins of the king's band. His son had obtained the reversion in 1717, of chamber musician to the king, and in 1703, that of composer; having given proofs of his abilities by many different works, but, above all, by his "Pyramus and Thisbe," composed in partnership with Francoeur.

He was succedingly appointed to all the musical posts of honour and profit under the royal patronage and that of the public. The close and uninterrupted friendship between this musician and Francoeur, does honour to the memory of both; having composed jointly, for 50 years, successful pieces, without discovering to which of them the greatest honour was due. Laborde. See Francoeur.

REBELLION originally signified a second resistance or railing of such as had been formerly overcome in battle by the Romans, and had yielded themselves to their subjection.

It is now generally used for a traitorous taking up of arms against the king, either by his own natural subjects, or by those formerly subdued; whether their view be to deprive him of the supreme authority, or whether they intend to refit his commands in some particular affairs, in order to impose conditions on him. Popular commotion is a concourse of people, tumultuously assembled, and resting the voice of their superiors, whether their designs be against those sup-
eriors themselves, or only some private persons. Such violent commotions are common when the people think themselves aggrieved, and are occasioned by no order of men so frequently as the tax-gatherers. (See the next article.) If the rage of the malcontents be particularly levelled at the magistrates, or others vested with the public authority, and they proceed to a formal disobedience or violent proceedings, it is called a "federation." When the evil spreads, infecting great numbers in the city or provinces, and subverts in such a manner, that the sovereign is no longer obeyed, such a dis
order custom has more especially distinguished by the name of "insurrection." All these violence disturbs the public order, and are crimes of state, even when arising from just causes of complaint. For violent measures are interdicted in civil society; the injured party should have recourse to the magistrates, to whom they may apply for redress; and if justice be not obtained from them, their complaints may then be laid at the foot of the throne. Every citizen should even patiently suffer supportable evils, rather than disturb the public peace. Nothing less than a denial of justice from the sovereign, or affected delays, can excuse the furious commotions of a provoked people; they in some measure justify themselves, if the evils be intolerable, and the oppressions great and manifest. But, it may be asked, what conduct shall the sovereign observe towards the insurgents? The reply in general is, that which shall at the same time be most conformable to justice, and most salutary to the state. If he is to repress those who uneccessi-
darily disturb the public peace; he is, by the same reasoning, to shew clemency towards unfortunate persons, to whom just cause of complaint has been given, and who are guilty only in having undertaken to do themselves justice; so that they have been wanting in patience rather than fidelity. The sovereign should consider that his rights are derived from thse of civil society, from the trufl reposed in him, from the obligation devolved upon him of watching over the welfare of the nation, of procuring its greatest happiness, and of maintaining in it order, justice, and peace. He will also duly distinguish the nature and degree of the different disorders which may disturb the state, oblige him to take arms, or substitute the means of force instead of those of authority. By considerations of this kind he will regulate his behaviour towards revolted subjects. It cannot be question-
tioned, that subjects rising against their prince without cause defere severe punishment; yet in this case the number of delinquents calls for the sovereign's clemency; shall he de
}

populate a city; or depopulate a province, in punishing their rebellion? Such a chastisement, however just in itself, becomes a cruelty when extended to so great a number of per-
sons. The Proclamation of the Netherlands against Spain had been totally unavoidable, every man of virtue would fill execute the memory of the duke of Alva, who made it his boast that he had caused above 20,000 heads to be struck off by the hands of the common executioner. Let not his fan
guinary imitators (fays the excellent Vattel) expect to jus
tify their enormities by necessity. Who was ever more un
deferredly infalutted by his subjects than Henry the Great of France? His conquests were ever accompanied by an uni
form clemency, and at length that excellent prince obtained the success he desired; he thereby gained over faithful sub
jects; whereas the duke of Alva left his master the United
Provinces. Tyrants alone will treat, as feditious, those
have and relapse citizens, who exhort the people to pre

erve themselves from oppression in the vindication of their rights and privileges; a good prince will command such vir

tuous patriots, provided their zeal be tempered with modera
tion and prudence. If he has justice and his duty at heart;
if he aspires to that immortal and unfurled glory of being
the father of his people; let him mistrust the flithf sugges
tions of a minister, who represents to him as rebels all those citizens who do not hold out their hands to chains, who re
fuce tamely to suffer the flames of arbitrary power.

The facile, and the moft just way thoroughly to appease feditious, is to give the people satisfaction; and if the insurrection has been without cause, which perhaps has never been the case, still an amnesty is to be granted where the offenders are numerous. When this amnesty is once published and ac
cepted, whatever has past must be buried in oblivion. A

man who makes any confidence of his word, is faithfully
to keep what he has promised to rebels themselves; i.e. to
those subjects who have revolted without reason or necessity. If his promises are not inviolable, what security have the rebels in treating with him? When they have once drawn the sword, they have nothing to do but, as one of the an
cients expressed it, to throw away the scabard. The prince
will then want the mild and salutary means of appeasing a revolt: to exterminate the rebels will be the only expedient
remaining. These will become formidable through depair: com
passion will bellow sincere on them; their party will increa
se, and the state will be in danger. Vattel's Law of Na
tions, b. iii. See Civil War.

Rebel is sometimes also used, in our ancient statutes, for a

person who wilfully breaks a law; and sometimes for a vil
lain disobeying his lord.

REBELLION, Commission of. See Commission.

REBELLIOUS Assembly, a gathering of twelve per
sons, or more, intending, going about, or practising,
unlawfully, and of their own authority, to change any laws
of the realm, or to destroy the incoherence of any park or
ground enclosed, banks of fish-ponds, pools, conduits, &c.
at the intent the same shall remain void, or that they shall
have way in any of the said grounds; or to destroy the deef
in any park, fish in ponds, coeys in any warren, dove
hous.
Rebus, a name-device, as Camden enligishes it; or an enigmatical reprentation of some name, &c. by using figures or pictures, instead of words, or parts of words. Such is that of the gallant mentioned by Camden, who expreffed his love to Rofe Hill, by painting in the border of his gown a rofe, a hill, an eye, a loofe, and a well; which, in the rebus style, is read, "Rofe Hill I love well."

The Picards have the honour of the invention of this notable kind of wit; whence the French, to this day, call it rebus de Picardie. Camden adds, that the English firft learnt it of them in the reign of our Henry III. by means of the garrifons we then had in Calais, Guinene, and other places bordering on Picardy.

Its origin is by Menage, &c. ascribed to the priets of Picardy, who, it feems, anciently, in carnival time, used every year to make certain libels, entitled de rebus que geruntur, being raiilleries on the intrigues and transaftions that had palled about the city; in which they made great ufe of fuch fort of equivoques and allufions, breaking and joining words, andsupplying them with paintings.

Camden tells us, the rebus was in wonderful effeem among our forefathers; and that he was nobody who could not hammer out of his name an invention by this wit-craft, and picture it accordingly.

The Sieur des Accordis has made an ample collection of the moft famous rebus de Picardie. And Mr. Camden has done something of the fame kind in his Remains.

Abel Druger's device in Ben Johnson's Alchenif, and Jack of Newbury, in the Spectator, are known to every body. But the rebus, being once raifed to flgn-post, grew out of fashion at court.

Yet has rebus antiquity on its fide, as having been in ufe in the pure Augustan age: Cicero, in a dedication to the gods, inferred Marcus Tullius, with a little pea, called by the Latins ricer, by us a chiefe pea. And Julius Caesar, in fome of his coins, ufed an elephant, called Cifur in thel Mauritian tongue. Add to thofe, that the two mint-masters in that age, L. Aquilus Florus, and Vocius Vitiulus, ufed, the firft a flower, the fecond a cafle, on the reverse of their coins.

Rebus, in Heraldry, a coat of arms which bears an alluflion to the name of the perfon; as three cafles, for Caffleton; three cups, for Butler; three conies, for Conifby; a kind of bearings which are of great antiquity.

Rebus is also ufed by the chemical writers, at times to signify four milk, and sometimes for what they call the ultimate matter of which all bodies are compounded.

Rebutter, from re, and the French bouter, to repel, or bar, in Law, the anwert of the defendant in a cause to the plaintiff's fur-rejoinder.

The plaintiff's anwert to the defendant's rebutter, is called a fur-rebutter.

Rebutter is alfo when a man warrants any land or hereditament to another, and the perfon making the warranty, or his heir, fues him to whom the warranty is made, or his heir or affignee, for the fame thing: if he, who is fo fed, plead the deed or fine with warranty, and pray judgment, if the plaintiff fhall be received to demand the thing which he ought to warrant to the party, against the warranty in the deed, &c. this is called a rebutter.

Again, if I grant to the tenant to hold fins impetitionis vagi, and afterwards implead him for waffe, he may debar me of the action, by fhewing my grant; which is likewife a rebutter.

Rec, in Geography, a river of France, which runs into the Sarre, at Sarre Alb.

Recanati, a town of the marquifate of Ancona; near which towards Macerata are feen the ruins of Helvia Ricina; a town built by the emperor Sept. Severus, and destroyed by the Goths; 8 miles N.N.E. of Macerata. N. lat. 43° 35'. E. long. 13° 39'.

Recango, in Rural Economy, a term provincially ufed to signify lited or defcoloured in stripes.

Recapitulation. See Palindry, or Retraclation.

Recapitulation, in Oratory, &c. a part of the peroration, or conclusion; called alfo anacephalys.

Recapitulation is a summary of the preceding discourse; or a concise, tranfient enumeration of the principal things intitled on at large in it; by which the memory of the hearer is refretched, and the force of the whole collected into one view.

An infance of this may be given in the peroration of Cicero's Manilam: "Quare, cum bellum ita necediturium fit, ut negligent non positi: ita magnum, ut accuratiffimum fit administrandum: & cum ei imperatorem præfere poftitis, in quo fit eximia bellis scientia, singularis virtus, clarissima auctoritas, egregia fortuna; dubitabis, Quirites, quin, &c."

In order to confitute a good repetition or recapitulation, it muft be short and concife: it is alfo convenient to recite things in the fame order in which they were at firft laid down; but sometimes a repetition is made, by running a comparifon between the speaker's own argument, and thofe of the adverfe party, and placit them in oppofition to each other; and this method Cicero takes in the conclusion of his third oration upon the Agrarian law. In fome cafes, when the difcourfe is very long, and the arguments intitled on have been many, the orator only mentions fuch things which he thinks of leaff consequence, by faying that he omits or poftles over them, till he comes to what is of greater moment, which he reprefents most fully. Ward's Orat. vol. i. leff. 18. See Prefenration.

Recaption, Recaptio, or Reprefal, in Law, is a remedy given to the party himfelf for an injury to his perfonal property. This happens, when any one hath deprived another of his property in goods or chattels personal, or wrongly detains one's wife, child, or fervant; in which cafe the owner of the goods, and the husband, parent, or maifter, may lawfully claim and retake them, wherever he happens to find them, so he be not in a notorious manner, or
or attended with a breach of the peace. Thus, e. g., if
my horse is taken away, and I find him in a common, a fair,
or a public inn, I may lawfully seize him to my own use; but
I cannot justify breaking open a private stable, or entering
on the grounds of a third person to take him, except he be
deliberately stolen, but must have recourse to an action at
law. Reclamation is unlawful, if it be done with intention
to smother or compound a larceny. See Restitution
of Stolen Goods.

Reclamation is also the taking a second diffracts of one
formerly disftrained for the same cause, and also during the
plea grounded on the former disftraits.

Reclamation is also the name of a writ lying for the party
thus disftrained to recover damages. See Replevin.

RECAPTURE, in Naval Injuries, denotes the re-
covery of a ship, or its cargo wholly or in part, after having
been taken by an enemy. For every loss occasioned by
capture, whether lawful, i.e. when made by a declared
enemy, according to the laws of war, or unlawful, i.e. when
it is against the rules established by the law of nations,
whether by friends or enemies, the insurer is liable, agree-
ably to the comprehensive and expressive words of the policy:
and in every case of capture the insurer is answerable, to the
extent of the sum insured, for the loss or damage suffered.
This may be either total, as where the ship and cargo are
not recovered; or partial, as where the ship is recaptured
or restored before abandonment; in which case the insurer is
bound to pay the salvage, and any other recovery or ex-
ception may have incurred by the recovery of his property.
The insurer is liable for a loss by capture, whether the prop-
erty in the thing insured be changed by the capture or not.
As to the length of possession by an enemy, which is deemed
sufficient to divest the property out of the original owner,
or the effect of a recapture in revesting it; these matters
which can never now come directly in question between the
insured and insurer, in any case of insurance upon real in-
terest. In gaming insurances, or insurances without interest,
indeed, when there was a recapture, the claim, as for a
total loss, seems formerly to have involved the question,
whether the property in the thing insured had, by the capture,
or any proceeding founded on it, been divested out of the
original owner, or not, before the recapture. Neverthe-
less, when a ship is insured "interest or no interest," it has
been repeatedly determined, that if the ship be taken, it is
a total loss, however illegal the capture may be, and though
the ship may be recaptured and restored to the owner. But
though no question can now arise between the insured and
the insurer, as to the effect of a capture or recapture, in
divesting or revesting the property; it may not be deemed
unimportant to inquire when a capture shall be deemed to
transfer the property to an enemy, and what shall be the
effect of a recapture in revesting it in the original owner.
The general opinion seems to be, that by the law of nations,
the property of things captured in war is changed when all
reasonable hope of recovering them is gone; and, with respect
to things movable, all reasonable hope of recovering them is
presumed to be gone when they are brought within the pro-
tection of the enemy's forts. Grotius says, that ships or
goods, taken at sea, become the property of the captors,
when they are brought into the enemy's harbours, or to the
place where his whole fleet is stationed; for then all hopes of
recovering them may be said to vanish. But, he adds, that
by the law of nations, as introduced among European states
in modern times, things are considered as captured,
when they have been 24 hours in the power of the enemy.
Others deny this rule of the law of nations, and infilt on
the rule of the Roman law, that the prize must be carried
infra praedicta before it can become the property of the
captors; and by "praedicta" Bynkerhook and its followers
understand the ships, the ports, the towns, and the fleets, of the enemy.
In our courts of admiralty, however, it has always been
held, by the marine law of England, independent of the
statute which commands restitution, and fixes the rate of
salvage, the property is not changed in favour of a vendee
or recaptor, so as to bar the original owner, till there has
been a regular sentence of condemnation; and in the reign
of king Charles II, a solemn judgment was given upon
this point; and restitution of a ship taken by a privateer was
decreed, after she had been fourteen weeks in the enemy's po-
fession, because she had not been condemned. The same doctrine
has, in several instances, prevailed in our courts of common
law. In one case it was held that nine days' possession by
the captor, and in another, that four years' possession, and
several voyages performed, will not change the property,
without a sentence of condemnation.

In general, whenever a ship is taken by the enemy, the
insured may abandon, and demand as for a total loss; and he
is not bound to make any claim or appeal in the enemy's
courts of admiralty, or to litigate there the validity of the
capture.

But the insured is in no case bound to abandon; and, as
the law now stands, no capture by the enemy can be fo total
a loss as to leave no possibility of recovery, for the jus polli-
mittit continues for ever, except in the case of a captured
ship converted into a ship of war. (Stat. 33 G. III. c. 66.
§ 42.) If the owner himself should retake his ship or goods,
he will be fully intitled to them; and if they be retaken at
any time, whether before or after condemnation, he will be
intitled to restitution, upon payment of a settled salvage.
Stat. 29 G. II. c. 34. § 24; and 33 G. III. c. 66. § 42.

The chance of the owner's recovering his property, does
not, however, fulfill the demand of the injured, as for a
total loss; but in the case of a recapture, justice is done
to the insurer by putting him in the place of the insured.
In questions upon policies of insurance, the nature of the
contract as an indemnity, and nothing else, is always liberally
considered.

When there has been a capture, whether legal or not,
and the ship has been recaptured or restored, the insurer is
bound to defray all necessary expenses which the insured has
been put to for the recovery of his property. He is there-
fore liable for a sum of money paid by the insured to the
captors, as a compromisé made bona fide, to prevent the ship
being condemned as prize. See RANSON.

It often happens that a recaptured ship is in a state to
prosecute her original voyage; and, in that case, it is the
interest of the captors, as well as of the other parties con-
cerned, that she should be permitted to do. The last
prize act (Stat. 33 Geo. III. c. 66. § 44.) has therefore
very properly provided, "That if a ship be detained before
she has been carried into an enemy's port, it shall be law-
ful for her, if the captors consent thereto, to prosecute her
voyage; and it shall not be necessary for the captors to
proceed to adjudication till six months after the recapture,
or till the return of the ship to the port from whence she
failed; and the master, owners, or agents, with the consent
of the captors, may dispose of their cargoes before ad-
judication; and in case the vessel shall not return to the port
from whence she failed, or the captors shall have no oppor-
tunity of proceeding regularly to adjudication within the
six months, on account of the absence of the said vessel,
the court of admiralty shall, at the instance of the captors,
declare restitution to the former owners, they paying salvages,
upon such evidence as to the court shall, under all the cir-
stances

Vol. XXIX.

3 T
RECAPTURE.

eumstances of the cafe, appear reasonable; the expence of such proceeding not to exceed fourteen pounds."

We shall here observe, that there is an obvious difference between capture and arrest of princes; the object of the one is prize, that of the other detention, with a design to restore the ship or goods detained, or to pay the value to the owner.

When a ship is detained in a port after a declaration of war, or the issuing of letters of reprisal, this more resembles a capture than a detention, and gives the injured an immediate right to abandon, as for a lobs by capture, even though no condemnation be pronounced, and though the ship be afterwards reforeed. The most frequent cause of detention is an embargo, which is a proclamation or order of state, usually issued in time of war or threatened hostilities, prohibiting the departure of ships or goods from some or all of the ports of such state until further order. An embargo laid on ships and merchandise in the ports of this kingdom by virtue of the king's proclamation, is strictly legal, when the proclamation does not contravene the ancient laws, or tend to establish new ones; but only to enforce the execution of such laws as are already in being, in such manner as the king shall judge necessary. But whether an embargo be legally or illegally laid, the injury to the owner, by the detention of his ship or goods, is the same; and the injured is equally liable for the lobs occasioned by it. If a ship be seized after a cessation of arms and preliminary articles of peace are signed, this shall not be deemed a capture, but only an arrest of princes. For the regulation of salvage upon a recapture, we refer to the article SALVAGE.

Capture by an enemy or a pirate, or an arrest of princes, or even an embargo, is prima facie a total lobs; and immediately upon the capture, or upon a mere arrest, or at any time while the ship continues under detention, the injured may elect to abandon, and give notice to the injured of his intention so to do; and thus entitle himself to claim as for a total lobs from the injured. For, from the moment of the capture, the owners lose their power over the ship and cargo, and are deprived of the free disposal of them; and, in the opinion of the merchant, his right of disposal being suspended or rendered uncertain, is equivalent to a total deprivation. It would therefore be unreasonable to oblige the injured to wait the event of capture, detention, or embargo.

There is this difference between a policy upon interest, and a wagger policy, that in the one cafe the injured may, if he thinks proper, abandon the moment he has notice of a capture or detention, and this will bind the underwriters, whatever may be the ultimate fate of the ship; but in the cafe of a wagger policy there can be no abandonment, because the injured has nothing to abandon.

But a capture or arrest does not necessarily, and at all events, terminate in a total lobs, so as to entitle the injured to abandon; for as he cannot abandon till he has received advice of the lobs; if, at the time he receives such advice, or before he has elected to abandon, he receive advice that the ship or goods injured are recovered, or are in safety, he cannot then abandon; because he can only abandon while it is a total lobs, and he knows it to be so; not after he knows of the recapture. Therefore, if a captured ship be retaken and permitted to proceed on her voyage, so that the sufferers but a small temporary inconvenience; this would only be a partial, and not a total, lobs.

On the other hand, a title to restitution upon a recapture does not necessarily, and at all events, deprive the injured of the right to abandon; for if, in consequence of the capture, the voyage be lost, or not worth pursuing; if the salvage be very high; if farther expense be necessary, and the injured will not undertake at all events to pay it, he may abandon. The rule is, that, if the thing injured be recovered before any lobs is paid, the injured is entitled to claim as for a total, or a partial lobs, according to the final event; that is, according to the state of the cafe at the time he makes his claim. There is no vested right to a total lobs, till the injured, having a right to abandon, elects to do so; for he is only entitled to an indemnity for his lobs as it stands at the time of the action brought, or offer to abandon.

But if, after a total lobs has been actually paid, the thing injured be recovered, the injured cannot oblige the injured to refund the money he has received; but he shall stand in the place of the injured, and so no injustice is done.

Cases are mentioned by Mr. Serjeant Marshall, which serve as examples to show that though a captured ship be recaptured, yet if the voyage be lost, the lobs will be total, and the injured will have a right to abandon.

By the marine law, the property was not changed by the capture, till after condemnation; and since the 29 Geo. II. c. 34, the "jus poellimini" continues for ever. A recapture does not in all cases prevent the lobs being total. If the voyage be absolutely lost, or be not worth pursuing; if the salvage be very high; if further expense be necessary; if the injured will not engage, at all events, to bear that expense, though it should exceed the value, or fail of success; under these, and many other similar circumstances, the injured may difentangle himself and abandon, notwithstanding there was a recapture. Upon a recapture the property returns to the original owner, pledged to the captors for the amount of the salvage; upon the payment of which he is intitled to restitution. If upon a recapture the captain, finding that the voyage cannot be pursued, and, acting fairly for the benefit of all concerned, sell the ship and cargo to pay the salvage, and thereby put an end to the voyage, the injured may abandon and recover as for a total lobs. However, a capture does not necessarily amount to a total lobs, nor does a recapture prevent its being total. If the captain purchase the ship from the captors for account of his owners, the money paid, being in the nature of salvage, is only partial lobs.

To this article we shall subjoin two or three remarks on the subject of abandonment, which do not elsewhere occur. A time should be fixed when the degree of the injured's responsibility should be ascertained. In several maritime states on the continent, politic regulations have been established, limiting the time, after a lobs has happened, within which the injured may abandon. In England we have no such positive regulation, nor any time limited by law for abandoning. But the courts have laid down a rule, better adapted to the purpose; and the rule is, that as soon as the injured receives advice of a total lobs, he must make his election whether he will abandon or not. If he determines to abandon, he must give the underwriters notice of this within a reasonable time after the intelligence arrives; and any unnecessary delay in giving this notice will amount to a waiver of his right to abandon; for unless the owner does some act, signifying his intention to abandon, it will be only a partial lobs, whatever may be the nature of the lobs, or the extent of the damage. If the injured in any manner prevent the abandonment, they shall pay the whole lobs, to the amount of the sum injured. If no intelligence be received of a ship within a reasonable time, it shall be presumed that the foundered at sea: when the time has elapsed which affords that presumption, the injured may abandon, and claim as for a total lobs. Marshall on Insurance, vol. ii.
Receipt or discharge given for or upon the payment of money.

And where any sum of money whatever shall be therein expressed, or acknowledged to be received in full of all demands.

And any note, memorandum, or writing whatsoever, given to any person for or upon the payment of money whereby any sum of money, debt, or demand, or any part of any debt or demand therein specified, and amounting to 2l. or upwards, shall be expressed or acknowledged to have been paid, fettled, balanced, or otherwise discharged or satisfied, or which shall import or signify any such acknowledgment, and whether the same shall or shall not be signed with the name of any person, shall be deemed and taken to be a receipt for a sum of money of equal amount with the sum, debt, or demand so expressed or acknowledged to have been paid, fettled, balanced, or otherwise discharged, or satisfied, within the intent and meaning of this schedule, and of the foregoing act, and shall be charged with a duty accordingly.

And any receipt or discharge, note, memorandum, or writing whatsoever, given to any person for or upon the payment of money, which shall contain, import, or signify any general acknowledgment of any debt, account, claim, or demand, debts, accounts, claims, or demands, whereof the amount shall not be therein specified, having been paid, fettled, balanced, or otherwise discharged or satisfied, or whereby any sum of money therein mentioned shall be acknowledged to be received in full, or in discharge or satisfaction of such debt, account, claim, or demand, debts, accounts, claims, or demands, and whether the same shall or shall not be signed with the name of any person, shall be deemed and taken to be a receipt for the sum of 500l. or upwards, within the intent and meaning of this schedule, and of the foregoing act, and shall be charged with the duty of 5l. accordingly.

By 43 Geo. III. c. 126, such receipt shall not be available in law or equity as fuch acknowledgment, or be given in evidence, unless duly stamped as aforesaid.

**Recarts, in Geography, a town of Portugal, in the province of Beira; 6 miles E. of Bragança Nova.**

**Recan.** See Arracan.

**Recoco, a town of the Ligurian republic, near the coast; 11 miles S.E. of Genoa.**

**Receipt, a port and harbour on the coast of Brazil.**

S. lat. 8° 19'.

**Receipt, or Receipt, in Commerce, an acquittance or discharge; or a written acknowledgment of having received a sum of money.**

Where the receipt is on the back of a bill, &c. it is usually called an endorsement.

Among tradesmen the receipt usually makes the second of the three articles of an account; the receipt contains the monies received; the two others the expense, and the return or balance.

By the 44 Geo. III. c. 98, the former stamp duties were repealed, and others imposed; by the 48 Geo. III. c. 149, these last were repealed, and the following were imposed; viz.

**Receipts exempted from stamp duty by any act or acts of the present session, relating to the assessed taxes.**

Receipts or discharges given by the treasurer of the navy for any money impounded or received by him for the service of the navy.

Receipts or discharges given by any agent for money impounded to him on account of the pay of the army or ordnance.

Receipts or discharges given by any officer, seaman, marine or soldier, or their representatives respectively, for or on account of any wages, pay, or pension due from the navy-office, army pay-office, or ordnance-office.

Receipts or discharges given for the consideration money, for the purchase of any share in any of the government or parliamentary fleets or ships, or for the proceeds and funds of the government and company of the bank of England, or for the East India company, or South Sea company, and for any dividend paid on any share of the said fleets or funds respectively.

Receipts given for money deposited in the bank of England, or in the bank of Scotland, or royal bank of Scotland, or in the bank of the British Linen company in Scotland, or in the hands of any banker or bankers, to be accounted for on demand, provided the same be not expressed to be received of or by the hands of any other than the person or persons to whom the same is to be accounted for; but if with interest, see Promissory Notes.

Receipts or discharges written upon promissory notes, bills of exchange, drafts or orders for the payment of money duly stamped according to the laws in force at the date thereof, or upon bills of exchange drawn out of, but payable in Great Britain.

Receipts or discharges given upon bills or notes of the governor and company of the bank of England; letters by the general post acknowledging the safe arrival of any bills of exchange, promissory notes, or other securities for money.

Receipts or discharges indorsed or otherwise written upon, or contained in any bond, mortgage, or other security, in any conveyance, deed, or instrument whatever, duly stamped according to the laws in force at the date thereof, acknowledging the receipt of the consideration money therein expressed, or the receipt of any principal money, interest, or annuity thereby secured.

Release or discharges for money by deeds duly stamped according to the laws in force at the date thereof.

Receipts or discharges given for drawbacks or bounties upon the exportation of any goods or merchandise from Great Britain.

Receipts or discharges for the return of any duties of customs upon certificates of over entry.

Receipts or acknowledgments of payments indorsed upon any bills, orders, remittance bills, or remittance certificates, drawn by commissioned officers, marshals, and surgeons in the navy, or by any commissioner or commissioners of the navy, under the authority of the act passed in the 35th year of his majesty's reign, for the more expeditious payment of the wages and pay of certain officers belonging to the navy.

---

**Recarts.** And all receipts, discharges, and acknowledgments of the description aforesaid, which shall be given for or upon payments made by or with any bills of exchange, drafts, promissory notes, or other securities for money, shall be deemed and taken to be receipts given upon the payment of money within the intent and meaning of this schedule and of the foregoing act.

**Exemptions from the preceding Duties on Receipts.**

Receipts exempted from stamp duty by any act or acts of the present session, relating to the assessed taxes.

Receipts or discharges given by the treasurer of the navy for any money impounded or received by him for the service of the navy.

Receipts or discharges given by any agent for money impounded to him on account of the pay of the army or ordnance.

Receipts or discharges given by any officer, seaman, marine or soldier, or their representatives respectively, for or on account of any wages, pay, or pension due from the navy-office, army pay-office, or ordnance-office.

Receipts or discharges given for the consideration money, for the purchase of any share in any of the government or parliamentary fleets or ships, or for the proceeds and funds of the government and company of the bank of England, or for the East India company, or South Sea company, and for any dividend paid on any share of the said fleets or funds respectively.

Receipts given for money deposited in the bank of England, or in the bank of Scotland, or royal bank of Scotland, or in the bank of the British Linen company in Scotland, or in the hands of any banker or bankers, to be accounted for on demand, provided the same be not expressed to be received of or by the hands of any other than the person or persons to whom the same is to be accounted for; but if with interest, see Promissory Notes.

Receipts or discharges written upon promissory notes, bills of exchange, drafts or orders for the payment of money duly stamped according to the laws in force at the date thereof, or upon bills of exchange drawn out of, but payable in Great Britain.

Receipts or discharges given upon bills or notes of the governor and company of the bank of England; letters by the general post acknowledging the safe arrival of any bills of exchange, promissory notes, or other securities for money.

Receipts or discharges indorsed or otherwise written upon, or contained in any bond, mortgage, or other security, in any conveyance, deed, or instrument whatever, duly stamped according to the laws in force at the date thereof, acknowledging the receipt of the consideration money therein expressed, or the receipt of any principal money, interest, or annuity thereby secured.

Release or discharges for money by deeds duly stamped according to the laws in force at the date thereof.

Receipts or discharges given for drawbacks or bounties upon the exportation of any goods or merchandise from Great Britain.

Receipts or discharges for the return of any duties of customs upon certificates of over entry.

Receipts or acknowledgments of payments indorsed upon any bills, orders, remittance bills, or remittance certificates, drawn by commissioned officers, marshals, and surgeons in the navy, or by any commissioner or commissioners of the navy, under the authority of the act passed in the 35th year of his majesty's reign, for the more expeditious payment of the wages and pay of certain officers belonging to the navy.
Receipts or acknowledgments of payments indorsed upon any bills drawn pursuant to any former act of acts of parliament, by the commissioners of the navy, or by the commissioners for managing the transport service, and taking care of sick and wounded seamen, upon and payable by the treasurer of the navy.

If any person shall write or sign any receipt liable to any stamp duty, without being first duly stamped as aforesaid; or with a stamp of a lower value than is herein directed; shall forfeit 50l. if the sum paid or expressed therein shall not amount to 100l. and 25l. if the sum amount to 100l. or upwards. 31 Geo. III. c. 27. f. 17. 35 Geo. III. c. 55. f. 8.

Every person who shall give any receipt or writing acknowledging the payment of money, in which a less sum shall be expressed than the sum actually paid or received, or who shall separate or divide the sum actually paid or received into divers sums, or shall write off any part of any debt, or demand, or be guilty of or concerned in any contrivance with intent to defraud his majesty, shall forfeit 50l. 35 Geo. III. c. 55. f. 9.

And the persons, or their agent, from whom any sum shall be due or payable, and who shall have paid such sum, may provide a stamp with the proper duty, or of some higher rate of duty than required, and demand of the person entitled to such sum, or any agent to whom the sum shall have been paid, a receipt for such sum, and also the amount of the duty thereon as aforesaid; and if such person refuse to give such receipt upon demand thereof, or to pay the amount thereof, every such person shall forfeit for each offence 10l. 43 Geo. III. c. 126. f. 5.

Stamps denoting the duties under former acts may be used, provided they be applied to receipts of the like amount as required by this act. f. 8.

And all vellum, parchment, and paper liable to any stamp duty as aforesaid, shall be stamped before the same be written or printed upon; or may be brought to the said commissioners or their officers to be stamped within 14 days after such receipts shall be given or bear date, and shall be stamped on payment of 5l. over and above the duty; and if brought after 14 days within one calendar month, on payment of 10l. over and above the duty. 31 Geo. III. c. 35. f. 19. 25. 35 Geo. III. c. 55. f. 15. 11.

All penalties by this act incurred may be sued for in the courts at Westminster; or any neighbouring justice may hear and determine any offence which subjects the offender to any pecuniary penalty; who may, on complaint made within three calendar months, summon the party accused, and the witnesses, and examine into the matter of fact; and on confession, or the oath of one witness, may give judgment therein, and levy such penalty by distress on the goods of the offender, which, if not redeemed within six days, may be sold; and such penalty shall be distributed half to the king, and half to the informer; and for want of sufficient distress, the offender shall be committed to prison for three calendar months, unless such penalty shall be sooner paid. 31 Geo. III. c. 25. f. 24. 25. 35 Geo. III. c. 55. f. 13. 13.

If any person shall find himself aggrieved by the judgment of such justice, he may, upon giving security to the amount of such penalty and costs, appeal to the next sessions, which shall happen 14 days next after such conviction, on giving reasonable notice; and in case such judgment be affirmed, they may award the person appealing such costs as to them shall seem meet. 1d.

Provided, nevertheless, that such justice may, where he shall see cause, mitigate any such penalty, so as not to reduce the same to less than one moiety thereof and above the costs. 31 Geo. III. c. 25. f. 26. 35 Geo. III. c. 55. f. 14.

Writs not appearing, having been duly summoned, without reasonable cause to be allowed by such justice, or refusing to give evidence, shall forfeit 40l. to be recovered in like manner. 31 Geo. III. c. 25. f. 27. 35 Geo. III. c. 55. f. 15.

Penfons counterfeiting or forging any stamp hereby directed to be made of shall be guilty of felony without benefit of clergy. 31 Geo. III. c. 25. f. 29. 35 Geo. III. c. 55. f. 17. 43 Geo. III. c. 126. f. 11.

All penalties given by any former act relating to the stamp duties shall extend to this act. 31 Geo. III. c. 25. f. 30. 35 Geo. III. c. 55. f. 18. 43 Geo. III. c. 126. f. 12.

Penfons sued or prosecuted on account of any thing done in pursuance of this act may plead the general issue and give the special matter in evidence; and if a verdict be for the defendant, or the plaintiff be non suited, treble damages shall be awarded against such plaintiff. f. 15.

By the 44 Geo. III. c. 98, the former duties on legacies under the care of the commissioners for stamp duties were repealed, and new duties were imposed. By the 45 Geo. III. c. 28, additional duties were imposed, and by the 45 Geo. III. c. 149, the following were imposed (being by f. 3. of this last act placed under the provisions of former acts relating to such duties,) and those imposed by former acts were repealed.

Schedule, Part III.

Legacies and succession to personal or moveable estate upon interment.

1. Where the testator, testatrix, or intestate, died before or upon the 5th of April 1805.

For every legacy, specific or pecuniary, or of any other description, of the amount or value of 20l. or upwards, given by any will or testamentary instrument of any person who died before or upon the 5th day of April 1805, out of his or her personal or moveable estate, and which shall be paid, delivered, retained, satisfied, or discharged, after the 10th of October 1808.

Also for the clear residue (when devolving to one person), and for every share of the clear residue (when devolving to two or more persons), of the personal or moveable estate of any person who died before or upon the 5th of April 1805 (after deducting debts, funeral expenses, legacies, and other charges first payable thereout), whether the title to such residue, or any share thereof, shall accrue by virtue of any testamentary disposition, or upon a partial or total intestacy; where such residue, or share of such residue, shall be of the amount or value of 20l. or upwards, and where the same shall be paid, delivered, retained, satisfied, or discharged, after the 10th of October 1808.

Where any such legacy, or residue, or share of such residue, shall have been given, or devolved, to or for the benefit of a brother or sister of the deceased, or any descendant of a brother or sister of the deceased; a duty at and after the rate of 2s. 10d. per cent. on the amount of the value thereof.

Where to or for the benefit of a brother or sister of the father or mother of the deceased; or any descendant of a brother or sister of the father or mother of the deceased; a duty at and after the rate of 4l. per cent. on the amount or value thereof.

Where to or for the benefit of a brother or sister of a grandfather or grandmother of the deceased, or any defendant of a brother or sister of a grandfather or grandmother of the deceased; a duty at and after the rate of 5l. per cent. on the amount or value thereof.

Where to or for the benefit of any person in any other degree of collateral consanguinity to the deceased, than is above described, or to or for the benefit of any stranger in blood to the deceased; a duty at and after the rate of 8l. per cent. on the amount or value thereof.

11. Where the testator, testatrix, or intestate, shall have died after the 5th of April 1805.

For every legacy, specific or pecuniary, or of any other description, of the amount or value of 20l. or upwards, given by any will or testamentary instrument, of any person who shall have died after the 5th of April 1805; either out of his or her personal or moveable estate, or out of or charged upon his or her real or heritable estate, or out of any monies to arise by the sale, mortgage, or other disposition of his or her real or heritable estate, or any part thereof, and which shall be paid, delivered, retained, satisfied, or discharged after the 10th of October 1808.

Also, for the clear residue, (when devolving to one person), and for every share of the clear residue (when devolving to two or more persons), of the personal or moveable estate of any person who shall have died after the 5th of April 1805, (after deducting debts, funeral expenses, legacies, and other charges first payable thereout), whether the title to such residue, or any share thereof, shall accrue by virtue of any testamentary disposition thereof, or upon a partial or total intestacy, where such residue, or share of residue, shall be of the amount or value of 20l. or upwards, and where the same shall be paid, delivered, retained, satisfied, or discharged after the 10th of October 1808.

And also for the clear residue (when given to one person), and for every share of the clear residue (when given to two or more persons), of the monies to arise from the sale, mortgage, or other disposition of any real or heritable estate, directed to be sold, mortgaged, or otherwise disposed of, by any will or testamentary instrument of any person who shall have died after the 5th of April 1805, (after deducting debts, funeral expenses, legacies, and other charges first payable thereout, if any), where such residue, or share of residue, shall amount to 20l. or upwards, and where the same shall be paid, retained, satisfied, or discharged after the 10th of October 1808.

Where any such legacy or residue, or any share of such legacy or residue, shall have been given, or have devolved, to or for the benefit of a child of the deceased, or any defendant of a child of the deceased; a duty at and after the rate of 1l. per cent. on the amount or value thereof.

Where to or for the benefit of a brother or sister of the deceased, or any defendant of a brother or sister of the deceased; a duty at and after the rate of 2l. 10s. per cent. on the amount or value thereof.

Where to or for the benefit of a brother or sister of the father or mother of the deceased; or any defendant of a brother or sister of the father or mother of the deceased; a duty at and after the rate of 4l. per cent. on the amount or value thereof.

Where to or for the benefit of a brother or sister of a grandfather or grandmother of the deceased; or any descendant of a brother or sister of a grandfather or grandmother of the deceased; a duty at and after the rate of 5l. per cent. on the amount or value thereof.

Where to or for the benefit of any person in any other degree of collateral consanguinity to the deceased, than is above described, or to or for the benefit of any stranger in blood to the deceased; a duty at and after the rate of 8l. per cent. on the amount or value thereof.

And all gifts of annuities, or by way of annuity, or of any other partial benefit, or interest, out of any such estate or effects as aforesaid, shall be deemed legacies within the intent and meaning of this schedule.

Exemptions.

Legacies and residues, or shares of residue, of any such estate or effects as aforesaid, given or devolving to or for the benefit of the husband or wife of the deceased, or to or for the benefit of any of the royal family.

And all legacies which were exempted from duty by the 39 Geo. III. c. 73, for exempting certain specific legacies, given to bodies corporate or other public bodies, from the payment of duty.

By f. 43. of 48 Geo. III. c. 119, the commissioners are authorized to remit penalties incurred before passing this act by non-payment of the duty on legacies, if the duty in arrear shall be paid on or before the 31st Jan. 1809.

By f. 44. in all cases not provided for by f. 43. where any receipt for any of the above matters shall be brought to the head office to be stamped after the expiration of three calendar months from the date thereof, it may be stamped on payment of the duty, together with the penalty incurred for not stamping the same in due time; and if the receipt have been signed out of Great Britain, and be brought to be stamped within 21 days after being received in Great Britain, and no penalty to be incurred.

The said duties to be under the management of the commissioners of the stamp duties, 33 Geo. III. c. 52. f. 3.

And in case of specific legacies, where the residue of any personal estate shall consist of property not reduced into money, the person taking administration of such effects, or by whom the duty ought to be paid, may set a value thereon, and offer the duty accordingly; and may, at his own expense, require the stamp commissioners to appoint a person to set such value, and such commissioners may accept the duty by such person with an appraisement, but if they shall not be satisfied with the value so set, they may appoint a person to appraise such effects, and to set the value thereof, and require the duty to be paid accordingly; but if the person who ought to pay such duty shall not be satisfied with such valuation, he may cause the same to be reviewed by the commissioners of the land-tax of the diocress where such effects shall be, at their next meeting, if fourteen days have elapsed before such meeting, and if not, at the next succeeding meeting, of which appeal six days notice shall be given to the stamp commissioners; and the said commissioners of the land-tax may appoint a person to appraise such effects, and to set a value thereon, and may hear and determine such appeal in like manner as appeals to them in other cases, and their judgment shall be final; and if the valuation made under the authority of such stamp commissioners shall not be appealed from within the time aforesaid, or shall be affirmed upon appeal, the duty shall be paid accordingly; and if any variation shall be made on such appeal,
appeal, the duty shall be paid according to such variation; and if the duty assessed in manner aforesaid shall exceed the duty offered to and refused by such flapm officers, the excess shall be borne by the person liable to pay such duty. If any dispute shall arise between persons entitled to such legacy, or residue, or taking administration as aforesaid, respecting the value thereof, or duty to be paid thereon, the duty shall be assessed by such flapm commissioners on reference to them by either party; and if the value of such property shall be in dispute, such flapm commissioners shall cause an appraisement to be made thereof, at the expense of the person liable to pay the duty, in manner aforesaid; and if such person shall be dissatisfied with such valuation, the same shall be reviewed and finally determined by the said commissioners of the land-tax, upon appeal to them within the time and in the manner aforesaid.

And if the effects whereon such duty is payable shall be within ten miles from London, such persons as shall be deputed by the said flapm commissioners shall act in their stead. f. 36 Geo. III. c. 52.

And if it shall appear to the said flapm commissioners, upon oath, to be administered by a justice, or master extraordinary in chancery, that the duty has been paid than ought to have been, by mistake, without intention of fraud, such mistake may be rectified by such commissioners, who may accept the duty really due within three calendar months, if no suit hath been instituted, and on payment of 10l. per cent. thereon by way of penalty. f. 50.

Every person paying or receiving money contrary to this act, who shall within twelve calendar months discover the other party offending, so as he be convicted thereof, shall be indemnified and discharged from all penalties against this act. f. 31.

And all powers of forming acts relating to the flapm duties, not hereby altered, shall be in force, in the execution of this act. f. 42.

Wherever any executor or administrator shall not have paid the said duties within time, the court of exchequer may, on application from the flapm office on satisfactory affidavit, grant a rule for such executor to shew cause why he should not deliver to the commissioners an account on oath of all legacies, or of the personal property paid or payable by him, and why the duties thereon have not been, or should not be forthwith paid, and may make such rule absolute where it appears proper. And registrars of ecclesiastical courts shall, within a month of requisition, deliver to the flapm office an account of wills and letters of administration in their custody, with particulars relating thereto, and extracts from any wills deemed necessary by the commissioners, on payment of fees agreed on or allowed by the ecclesiastical court, on pain of 50l. recoverable by information by the attorney-general. 42 Geo. III. c. 99. f. 2. 5.

And by the 5 W. c. 21, the probate of the will or letters of administration of any common soldier or seaman, slain or dying in the service, shall be exempt from the flapm duties. f. 65.

RECEIPT, or RECEIPT, in Law. See RECEIPT.
RECEIPT of Homage. See RECEIPT.
RECEIPT of the Exchequer. See COURT of Exchequer.
RECEIPT, in Medicine. See RECEIPT.
RECEIPT, Auditor of. See AUDITOR.
RECEIVER, or RECEIPT, in Chemistry, a globe-shaped vessel, which is adapted to the neck or beak of an alembic, retort, or other distillatory vessel, in order to collect, receive, and contain the products of distillations.

Receivers should be made of glass, not only because this matter refills the action of the strongest and most corrosive

f)ubstances, but also because being transparent, it allows the operator to see through it, and to judge by the frequency of the drops, if the distillation be too quick or too slow, and also if the quantity and nature of the substances that come over be such as are required.

Almost all receivers are kinds of bottles of different sizes, of a spherical form, the necks of which are cut short, and each of which is pierced with a small hole in its lateral or upper part, to give vent to the air or vapours, which are too expansive. Receivers of this form are called balloons; which fee. Some receivers are matrassells with long necks. These are generally adapted to the beak of an alembic. The long neck serves to keep the belly of the receiver, where the liquor is collected, at a proper distance from the fire.

Receivers have different forms for particular operations. Such are those which have two or three beaks, either to be adapted to other receivers, or to admit at the same time the necks of several distillatory vessels, when the intention of the operator is, that the vapours of different substances should meet in the same receiver. Such also are receivers for essential oils, obtained from aromatic plants distilled with water, which are so made, that they are never full, but that the water runs out, and leaves the oil behind. These are a kind of glas eucubits, which contract as they rise higher; so that their neck or upper opening is but nearly of a convenient size to receive the beak of the worm. These receivers have another opening above the middle of the swelling or belly; and to this opening is joined a glass tube, which bends and rises vertically along the outer part of the receiver, so as to be within two inches and a half as high as the upper opening. At this height the tube bends again towards the side opposite to the body of the receiver, to pour into another vessel the liquor which arises there. It forms the figure of an S.

When this receiver is to be used, it is to be placed vertically under the beak of the worm. During the distillation, the liquor rises to an equal height in the body of the receiver, and in the crooked tube: when, therefore, the height of the liquor in the receiver becomes greater than the height of the tube, it must begin to flow from the mouth of this tube into another vessel placed upon purpose to receive it; but as essential oils are either lighter or heavier than water, and as they are, therefore, always collected either above or under the water, and as the liquor which distilis itself through the tube is taken from the middle part of the receiver, nothing but water can be evacuated at the mouth of the pipe, while the oil always remains in the receiver. With such a receiver distillation may be performed without the trouble of changing the vessels. Macquet’s Chem. Dict. See Distillation and Laboratory.

RECEIVER of an Air-Pump, is part of its apparatus: being a glassy vessel placed on the top of the plate, out of which the air is to be exhausted. To an air-pump belong various receivers, of various forms and sizes, and serving for various purposes. See Air-Pump.

RECEIVER, Exhausted, in Pneumatics. See Exhausted. And for the method of repairing those that are cracked, see Cement.

RECEIVER, Receiver, or Receptacle, in Law, is used commonly in the bad sense, for such as knowingly receive stolen goods from thieves, and conceal them.

This offence is only a misdemeanor at common law; however, by the statutes 3 & 4 W. & M. c. 9 and 5 Ann. c. 31, the offender is made accessory to the theft and felony. But because the accessory cannot in general be tried, unless with the principal, or after the principal is convicted, the receivers
RECEIVERS by that means frequently eluded justice; to remedy which it is enacted by statute 1 Ann. c. 9. and 5 Ann. c. 31. that such receivers may be still prosecuted for a misdemeanor, and punished by fine and imprisonment, though the principal felon be not before taken, so as to be prosecuted and convicted. And in case of receiving stolen lead, iron, and certain other metals, such offence is, by statute 29 Geo. II. c. 50. punishable by transportation for fourteen years. So that now the prosecutor has two methods in his choice: either to punish the receivers for the misdemeanor immediately, before the thief is taken (Foster. 373.); or to wait till the felon is convicted, and then punish them as accessories to the felony. But it is provided by the same statutes, that he shall only make use of one, and not both of these methods of punishment.

By the same statute also (29 Geo. II. c. 50.) persons having lead, iron, or other metals in their custody, and not giving a satisfactory account how they came by the same, are guilty of a misdemeanor, and punishable by fine and imprisonment. And by statute 1 Geo. III. c. 48. all knowing receivers of stolen plate or jewels, taken by robbery on the highway, or when a burglary accompanies the stealing, may be tried as well before as after the conviction of the principal, and whether he be in or out of custody; and, if convicted, shall be adjudged guilty of felony, and transported for fourteen years. By Stat. 21 Geo. III. c. 68. the receiving of any stolen copper, brass, bell-metal, or unfinish fixed to any building, or any iron-rials or fencing set up in any court or other place, is made transportation for seven years, or three years' imprisonment to be kept to hard labour. By Stat. 21 Geo. III. c. 69. the receiving of stolen pewter of any kind is subjected to the like penalty, although the principal has not been convicted. By Stat. 22 Geo. III. c. 58. the receiving of any stolen goods, (except lead, iron, copper, brass, bell-metal, and folder,) is made a misdemeanor, punishable by fine and imprisonment, or whipping, as the court shall appoint; which shall exempt the offender from being punished as accessory, although the principal be afterwards convicted, and the offence shall appear to be grand larceny, or some greater offence. (See Larceny.) For the punishment of receivers of goods stolen by bum-boats, &c. on the river Thames, see Stat. 2 Geo. III. c. 28. § 12. Receivers of linen goods stolen from the bleaching-grounds are, by Stat. 18 Geo. II. c. 27. declared felons without benefit of clergy. In France, receivers are punished with death; and the Gothic constitutions distinguished also three sorts of thieves: "unum qui confilium daret, alterum qui contraclaret, tertium qui receperat et occulterat; parsi pane singulos obnoxious."

Receivers also denotes an officer, of which there are various kinds, denominated from the particular matters they receive, the places where, or the persons for whom, &c.

As receiver of rents; receiver-general of the customs; receiver of the fines, upon original writs in chancery, &c.

Receiver-General of the Duchy of Lancaster, is he who gathers all the revenues and fines of the lands of the said duchy, all forfeitures, allements, &c.

Receiver-General of the public revenue is an officer appointed in every county, to receive the taxes granted by parliament, and remit the money to the treasury.

Receiver's Office. See Greenwich Hospital.

Recent Fruits. See Fruit.

Receptacle of Stall Manure, in Agriculture, the place where the various matters from the stals, and other places where animals are kept, are deposited and laid up.
unles where liquid manure is more in demand than that of the bulky kind.

From the flow progresses made by manures of this sort to maturation, in the winter feation, in the open air, even when piled up in the dirt situations, on account of its being constantly frosted or saturated with moisture, and exposed to the effects of the cold atmosphere, the plan of giving receptacles of this sort a long oval square form, and covering them with roofs, to free them wholly from rain, as well as to defend them from cold, has been hit upon, and recommended from authority. As by thus affording the articles of manure the means of passing into the state of fermentation, in the winter months, their putrefaction and decay would be beneficially promoted, for the use of the more early crops of the sprig. But how far the advantage, gained in this way, may equal or be superior to the expence of building, and extra labour in the removals of the manure, is a point which is by no means yet fully decided. And the superior benefits, which have lately been derived from the use of manure in its more raw or green state, render all such schemes perhaps of less importance than would otherwise be the case.

As it is a matter of great consequence to prevent the excessive waste of this sort of manure, which at present frequently takes place in most parts of the country, it has been suggested by an experienced writer, who has attended much to the subject, and thought a great deal upon it, that piling it in shallow receptacles or basins, and conducting the liquor, when not wanted for moistening the piles of manure, which overflows from them, to reservoirs or catch-pools, in order to stop, deposit, and arrest the heavier and more gross particles that may be conveyed in it, and to provide a valuable collection of liquid manure in particular situations, and of rich maddy matters in others, are the most appropriate practical means of accomplishing the matter, in an easy and cheap way, that can be adopted or had recourse to. See Dung, Farm-Yard, Homestead, Manure, Reservoir, and Yard Manure.

RECEPTACULUM, Receptacle, in Botany and Vegetable Physiology, is the seventh, or last, part of fructification distinguished by Linnaeus, being the common basis, or point of connection, of the others. (See FRUCTIFICATION.) It is evident that such a part must exist, under some shape or other; yet the receptacle is not always distinguished by any particular figure. In simple flowers it is often little more than a mere point; in compound ones it is very remarkable and important, serving, by its differences of structure, to afford very good generic distinctions. The receptacle of the Daily, Bellis, is conical; that of Chrysanthemum convex. In Spharandus this part is very nearly globular, while in some species of Centaurea and Cardina it is either flat, or slightly concave. In Stenobus it is naked, destitute of hairs or scales between the florets or seeds; while in Cardius it is hairy, and in Anthemis variously scaly. This last genus differs, by the character in question alone, from Chrysanthemum, whose receptacle is naked; but the character is not quite so natural, in this case, as could be wished. Mr. Brown has observed, that it affords not even a certain artificial distinction, in the Chrysanthemum indicum of the gardens, Curt. Mag. t. 327; which Wilde- now, like M. de Ramatuelle and professor Desfontaines, has referred to Anthemis, because they found the receptacle to be scaly. We are convinced they are in the right, and yet this appears to be the very same plant with Chry- santhemum indicum, the scales of the receptacle being variable, and sometimes almost, if not altogether, evanescent. Some genera of this class have a cellular, or honeycomb-like receptacle, as Onopordum, and Tolpis (Crepis barbata of Linnaeus). In that case the edges of the cells are variously jagged, toothed, or fringed, and they now and then are fearfully distinguishable from the reticulations or rugosities of some naked receptacles.

The receptacle of the floures, in Linnaean language, means the area or space between the flamen and sepals, in certain genera whose germen is inferior; as the whole umbiliferous order, in which the part in question is more or less tenuis, often coloured, and affumes a glandular aspect. The receptacle of the fees is not unfrequently a distinct part from the capsule or its valves, serving to connect the fees therewith. (See an example of it in Recet- tea.) The racbis, or common flaks of a spike, or spikelet, in Graffius, is also termed a receptacle.

In some plants the receptacle undergoes great changes, acquiring a different texture in the fruit, from what it had in the flower. Thus, the whole fruit, as we call it, of the Fig, (see Ficus), is a common receptacle, at first coriaceous, and, like the rest of the plant, containing a milky, somewhat acid, juice. It forms a bag, lined with flowers or florets, and having a small aperture at the top. After the flowers are past, this bag becomes pulpuy, coloured, and full of sweet aromatic juice. So the fruit of the Strawberry, (see Fragaria,) is but an originally small dry receptacle, subsequently enlarged, and become pulpuy, whose outside is studded with naked fees. In Bryoffemata, described under our article Pappirus, the separate flaks of each germs becomes the enlarged and pulpuy supporter of a naked feed. In Pollichia, (see that article,) the common receptacle of the flowers, minutely scaly, and hardly discernible, in its earlier state, changes to a congeries of white, juicy, sweet, tooth-like scales, elevating the feeds in their appropriate withered perianths, and altogether constituting one of the most extraordinary pulpuy fruits that we have ever met with. A similar change of substance is observable in the calyx of the Mulberry, as well as in Consuella Zanonis; a change common and natural in the germens of pulpuy fruits, though rare in the particular parts of which we have been speaking.

RECEPTACULUM Gynii, in Anatomy, that portion of the trunk of the absorbing vessels, into which the luecal absorbents pour the fluids which they have taken up in the alimentary canal; it is usually rather larger than the neighbouring portions of the vessel, and sometimes very considerably so. See ABSORBENTS.

RECEPTARI, a term of reproach used for such physicians as wrote pompous receipts for loads of medicines, more confuting the good of the apothecary than the patient; as also for such as gave receipts for general medicines, to be used at the discretion of people wholly unacquainted with the nature of diseases.

RECEPTION, Receptio, in Philosophy, denotes the fame with passion, confidered as op posed to action.

Reception is also properly used for the manner of treating or entertaining a person; and the solemnities and ceremonies practised on that occasion. See Entry.

The reception of ambassadors is usually performed with a great deal of pomp.

Reception is sometimes also used for the act of approving, accepting, and admitting a thing. See Acceptance.

The Cannon law only binds where it is received: the civil law is received in some countries, and not in others.

The French would never receive the council of Trent, the Spanish inquisition, nor the dogmata of the ultramontane canons.
RECEPTION, in Astrology, is a dignity befalling two planets when they exchange houses; 6. gr. when the fun arrives in Cancer, the house of the moon; and the moon, in her return, arrives in the fun's house.

The same term is also used, when two planets exchange exaltation.

RECEPTITIOUS GOODS. See Goods.

RECESSION of the Equinoxes. See PRECESSION of the Equinoxes.

RECENSUS, a word used by some medical writers to expres an abscess, or suppuration.

RECESSION Imperii, Recens of the Empire, a phrase used in speaking of the affairs of Germany; signifying a collection of the votes or determinations of a diet.

At the end of each diet, before it breaks up, they gather together all their resolutions, and reduce them into writing; the act which contains them they call the recens imperii, because made when on the point of retiring.

RECEY für Oster, in Geography, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the district of Chatillon; 15 miles S.E. of Chatillon. The place contains 865, and the canton 5913 inhabitants, on a territory of 250 kilometres, in 17 communes.

RECHABITES, a kind of religious order among the ancient Jews, instituted by Jonadab the son of Rechab; and comprehending his family and posterity.

Their founder prescribed them three things: first, Not to drink any wine. Secondly, Not to build any houses, but to dwell under tents. Thirdly, Not to sow any corn, or plant any vines.

The Rechabites observed these rules with great strictness, as appears from Jerem. xxxv. 6, &c. Whence St. Jerom, in his thirteenth epistle to Paulinus, calls them monachi, monks. Jonadab, their founder, lived under Jehoshaph, king of Judah, contemporary with Jehu, king of Israel; his father Rechab, from whom his posterity were denominat d, descended from Raguel or Jethro, father-in-law to Moses, who was a Kenite, or of the race of Ken; whence Kenite and Rechabite are used as synonymous in scripture.

The Kenites entered the promised land with the Hebrews, and dwelt in the tribe of Judah, about the Dead sea. They were distinguished from the Israelites by their retired fort of life, and by their contempt of cities and houses. Serrurius distinguishes the ancient Rechabites defended from, and instituted by, Jethro, from the new Rechabites of Jonadab. The union of Jonadab laid no obligation on the other Kenites, nor on the other descendants of Jethro. This they continued to observe above 300 years. Jehu began to reign A.M. 3120, and Jehoiakim, king of Judah, was put to death A.M. 3455, B.C. 599; but in the last year of Jehoiakim, king of Judah, Nebuchadnezzar coming to besiege Jerusalem, the Rechabites were forced to take refuge in the city, still, however, lodging in tents. During this siege, Jeremiah received orders from the Lord to converse with the disciples of Rechab, to invite them into the temple, and to offer them wine to drink. But the Rechabites would not accept the offer.

The Rechabites were, probably, led captive, after the taking of Jerusalem by the Chaldeans. (See Psalm lxix.) They returned from their captivity, and settled in the city of Jabez beyond Jordan. (See 1 Chron. ii. 53.) Some have suggested, that the Alids of the Maccabees, (1 Macc. ii. 42. vii. 15, and 2 Macc. xiv. 6.) were successors and followers of the Rechabites. Others have con founded them with the Effenes. But it is certain, that the manner of life of the Effenes was very different from that of the Rechabites, as appears from Josephus, Antiq. lib. xviii. cap. 2, who informs us, that the Effenes had huts, and inhabited houfes, but had neither wives nor children; and did not perform their religious ceremonies with the other Jews at Jerusalem: all which was contrary to the practice of the Rechabites.

RECHING, in Hunting, the driving back of the deer, or other beasts, into the forests, chases, &c. which had droggled out into the copses or thickets, &c.

Anciently there were offices of rechacers of the deer believed by the king on gentlemen, or old hunters, with salaries for the keeping of running dogs to rechace the deer into the forests, and then to beat the dogs off, without pursuing any farther.

RECHANGE, in Commerce. See RE-EXCHANGE.

Rechange is also used at sea for such tackle as is kept in reserve aboard the ship, to serve in case of failure of that already in use. See Tackle.

The Levantines use the word reçoître or refaire in the same sense.

RECHARGE of a Fire Arm, is a second loading, or charge. The recharge should never be so deep as the first charge, lest the piece, being over heated, should burst.

RECHBERG, in Geography, a town of Austria; eight miles N.W. of Grein.

RECHE, a river of France, which runs into the Aisne, near Malmedy.—Alfo, a town of England, in the county of Cambridges, on the river Cam, formerly a place of great trade, and before the draining of the fen, a port for vessels of considerable burthen; five miles W. of Newmarket.

RECHEAT, in Hunting, a lefion which the huntsman winds on the horn, when the hounds have left their game, to call them back from pursuing a counter-foe.

RECHENBURG, in Geography, a town of Saxony, in the circle of Erzgebirg; four miles S.E. of Frauenstein.

RECHIA, a town of Servia; 100 miles W. of Nijia. N. lat. 43° 12'. E. long. 19° 31'.

RECHICOURT, a town of France, in the department of the Meurthe, and chief place of a canton, in the district of Sarrebourg; five miles N. of Blanmont. The place contains 992, and the canton 8516 inhabitants, on a territory of 21.7½ kilometres, in 17 communes.

RECHNITZ, a town of Hungary; six miles S.S.W. of Guntz.

RECHPERG, a town of Austria; two miles N. of Stain.

RECMUS, among the Romans, a kind of square mantle, or veil, worn by women on the head. Salmus will have it to have been a fort of gown used by the Roman ladies, and tucked up before with a square pin, or a purple colour.

RECINA, in Geography, a town of the marquisate of Ancona; three miles N.W. of Macerata.

RECIPE, in Medicine, a prescription, or formula, of a remedy, appointed to be administered to a patient. See PRESCRIPTION.

It is thus called, because always beginning with the word recipe, take; ordinarily expressèd by the abbreviation R.

RECIPIANGLE, or RECIPEND-ANGLE, a mathematical instrument, serving to take the quantity of angles; used especially in the drawing plans of fortifications.

The recipiangle was formerly a popular instrument among the French, but little known among us; it is usually very simple,
RECIPIENT, in Arithmetie and Algebra, is the quotient arising from the division of unity by any number or quantity. Thus, the reciprocal of \( a = \frac{1}{a} \), the reciprocal of \( \frac{b}{y} = \frac{y}{b} \), and so on.

**Reciprocal Equations**, in Algebra, are those equations which contain several pairs of roots which are the reciprocals of each other. Thus, an equation whose roots are \( a \), \( b \), \( \frac{1}{a} \), \( \frac{1}{b} \) &c. is called a reciprocal equation. Some authors define reciprocal equations, to be those equations whose coefficients proceed in the same order from both extremes, and reciprocally equal to each other; thus, \( a x^2 + b x + c = 0 \) is a reciprocal equation; but this form ought rather to be considered as a necessary property of these equations, by which they may be readily distinguished, than to be employed in the definition of them; it being doubtfles the reciprocity of the roots from which they have received their peculiar appellation.

The solution of these equations may always be made to depend upon others of half the original degree, when the equation is of even dimensions; or upon half the dimension minus 1, when it is odd.

Thus far, in fact, this property is not exclusively due to reciprocal equations, as the fame may be done in all cases where any similar relation is known to have place between the roots of an equation, whether by multiplication, division, addition, or subtraction; but in these cases there is nothing in the form of the equation by which such relations may be known to have place, whereas in reciprocal equations their reciprocity becomes immediately obvious by the peculiar order of their co-efficient, these being the same from both extremes, both with regard to sign and magnitude. Hence any equation of the form

\[
x^n + a x^{n-1} + b x^{n-2} + \ldots + b x + a x + 1 = 0
\]

is immediately known to be reciprocal, and we may proceed in its solution as follows.

First, if the equation be of odd dimensions, as

\[
x^{n+1} + a x^n + b x^{n-1} + \ldots + b x + a x + 1 = 0
\]

then it is obvious that either \( +1 \) or \( -1 \), is one of its roots, for either \( +1 \), or \( -1 \), substituted for \( x \), according as the signs of the co-efficients may require, will obviously render the whole expression equal to zero, and is therefore a root of the equation. The equation may, therefore, be immediately reduced to another of lower dimensions by division, according to the known theory of equations; thus, let the proposed equation be

\[
x^3 - 5 x^2 + 7 x^2 - 7 x^2 - 5 x + 1 = 0
\]

Here \( x = -1 \) is obviously one of the roots, as this substituted for \( x \) renders the whole equal to zero; and consequently the whole equation is divisible by \( x + 1 \), according to the known theory of equation, which division being made, we have, for our reduced equation,

\[
x^3 - 6 x^2 + 13 x^2 - 6 x + 1 = 0
\]

which is now of even dimension one degree less than the original equation, and still reciprocal. We need, therefore, only consider equations of the latter form; viz. those of which the index of the highest power is an even number.

Let \( x^n + p x^{n-1} + q x^{n-2} + \ldots + g x + b x + 1 = 0 \)

be any reciprocal equation, whose roots are \( a, \frac{b}{a}, \frac{1}{b}, \ldots \),

**RECIPIENT**
RECIPROCAL EQUATIONS.

Find the two values of \( z \) in the equation \( z^2 + (p - 1) z + q - p - 1 = 0 \), and call them \( r, r' \); then \( x = \frac{1}{r} \) or \( \sqrt{\frac{1}{r'}} \), \( \frac{1}{r'} \) or \( \sqrt{\frac{1}{r}} \).

Find the three values of \( z \) in the cubic equation \( z^3 + z^2 + (q - 3) z + r - 2 = 0 \), and call them \( r, r', r'' \); then
\[
x = \frac{1}{r} \pm \sqrt{\left(\frac{1}{r'}\right)^2 - 1}, \quad x = \frac{1}{r'} \pm \sqrt{\left(\frac{1}{r''}\right)^2 - 1}
\]

6th degree. \( x^4 + \beta x^3 + q x^2 + \rho x + 1 = 0 \).

Find the three values of \( z \) in the cubic equation \( z^3 + z^2 + (q - 3) z + r = 2 = 0 \), and call them \( r, r', r'' \); then
\[
x = \frac{1}{r} \pm \sqrt{\left(\frac{1}{r'}\right)^2 - 1}, \quad x = \frac{1}{r'} \pm \sqrt{\left(\frac{1}{r''}\right)^2 - 1}
\]

7th degree. \( x^5 + \beta x^4 + q x^3 + \rho x^2 + p x + 1 = 0 \).

Find the three values of \( z \) in the cubic equation \( z^3 + z^2 + (q - 3) z + r - 2 = 0 \), and call them \( r, r', r'' \); then
\[
x = \frac{1}{r} \pm \sqrt{\left(\frac{1}{r'}\right)^2 - 1}, \quad x = \frac{1}{r'} \pm \sqrt{\left(\frac{1}{r''}\right)^2 - 1}
\]

8th degree. \( x^6 + \beta x^5 + q x^4 + \rho x^3 + p x^2 + r x + 1 = 0 \).

Find the four values of \( z \) in the equation \( z^4 + \beta z^3 + (q - 4) z^2 + (r - 3 \beta) z + s = 2 = 0 \), and call them \( r, r', r'', r''' \); then
\[
x = \frac{1}{r} \pm \sqrt{\left(\frac{1}{r'}\right)^2 - 1}, \quad x = \frac{1}{r'} \pm \sqrt{\left(\frac{1}{r''}\right)^2 - 1}, \quad x = \frac{1}{r''} \pm \sqrt{\left(\frac{1}{r'''}\right)^2 - 1}
\]

9th degree. \( x^7 + \beta x^6 + q x^5 + \rho x^4 + p x^3 + r x^2 + s x + 1 = 0 \).

Find the four values of \( z \) in the equation \( z^4 + (p - 1) z^3 + (q - 3) z^2 + (r - 2 \beta) z + s = 2 = 0 \), and call them \( r, r', r'', r''' \); then \( x = \frac{1}{r} \pm \sqrt{\left(\frac{1}{r'}\right)^2 - 1}, \quad x = \frac{1}{r'} \pm \sqrt{\left(\frac{1}{r''}\right)^2 - 1}, \quad x = \frac{1}{r''} \pm \sqrt{\left(\frac{1}{r'''}\right)^2 - 1}
\]

A reciprocal equation of the 10th and higher powers, requires the general solution of equations of the 5th and higher powers, and therefore cannot be exhibited analytically. Bonnycastle's Algebra, vol. i.

Binomial equations are all reciprocal equations of a peculiar kind, which renders them all resoluble by means of certain trigonometrical formulæ.

Binomial equations are all reducible to the form \( x^n \pm 1 = 0 \); or \( x^n = 1 \); or \( x^n = -1 \). Where it is obvious, that if \( m \) is even, or \( m = 2n \), then \( x^n = 1 \) will have two real roots, \( \pm 1 \), and \(-1 \); and \( x^n = -1 \) will have two of its imaginary roots \( \pm i \), and \(-i \); so that, in both cases, such an equation may be reduced two degrees lower, by dividing it by \( x^2 - 1 \), or \( x^2 + 1 \), and the resulting equation will be a reciprocal one, having each of its coefficients equal to unity. If \( m \) be odd, then the equation will necessarily have one real root, and no more, which will be \( +1 \) in the first case, and \(-1 \) in the second; consequently, such an equation can be reduced but one degree, the fame as above stated. We may, therefore, find a direct solution for all binomial equations of odd dimensions as far as the 9th power, and of even dimensions as far as the 10th power, by the principles and formulæ already given, by merely making \( p = 1 \), \( q = 1 \), \( r = 1 \), &c., and it would, therefore, be useless to repeat them again in this place; we shall proceed immediately to the general solution of binomial equations, on the principles of analytical trigonometry.

All the imaginary roots of the equation
\[
x^n - 1 = 0
\]
are contained in the general formula
\[ x^3 - 2 \text{ cof.} \frac{2 \ell \pi}{n} x + 1 = 0; \]
\( \ell \) being any integer not divisible by \( n \), and \( \pi \) representing the semi-circumference. For it is a known trigonometrical property, that if
\[ 2 \text{ cof.} y = x + \frac{1}{n} \]
them two equations we readily draw the two following; viz.
\[ x' = 2 \text{ cof.} \quad y \cdot x + 1 = 0 \]
\[ x'' = 2 \text{ cof.} \quad n \cdot y \cdot x + 1 = 0 \]
which have necessarily one common root, being both derived from the same value of \( x \); and since there are both reciprocal equations, if \( x \) be one root, \( x = \frac{1}{n} \) will be another; they have therefore two roots common, and consequently, from the known theory of equations, the former is a divisor of the latter. If, now, we make \( y = \frac{2 k \pi}{n} \), or \( ny = 2 k \pi \), these equations become
\[ x^3 - 2 \text{ cof.} \frac{2 k \pi}{n} x + 1 = 0 \]
\[ x^n - 2 \text{ cof.} \frac{2 k \pi}{n} x^n + 1 = 0 \]
But the cof. \( 2 \frac{k \pi}{n} = 1, 2 \pi \) representing the whole circumference; therefore the latter equation is the same as
\[ x^n - 2 x^n + 1 = 0, \text{ or } (x^n - 1)^2 = 0, \]
the divisor of
\[ x - 2 \text{ cof.} \frac{2 k \pi}{n} x + 1 = 0; \]
that is, the roots of the equation
\[ (x - 1)^2 = 0, \text{ or } x^n - 1 = 0, \]
are all contained in the general formula
\[ x^3 - 2 \text{ cof.} \frac{2 \ell \pi}{n} x' + 1 = 0; \]
and, therefore, by giving to \( k \) the successive values 1, 2, 3, \( \ldots \), \( \frac{1}{2}(n - 1) \), the following formulae will be obtained; viz.
\[ x^3 - 2 \text{ cof.} \frac{2 \pi}{n} x + 1 = 0 \]
\[ x^3 - 2 \text{ cof.} \frac{4 \pi}{n} x + 1 = 0 \]
\[ x^3 - 2 \text{ cof.} \frac{6 \pi}{n} x + 1 = 0 \]
\[ \ldots \]
\[ x^3 - 2 \text{ cof.} \frac{(n - 1) \pi}{n} x + 1 = 0 \]
which contain among them all the imaginary roots of the equation \( x^n - 1 = 0. \)

And if, instead of making \( y = \frac{2 k \pi}{n} \), as above, we make
\[ y = \frac{(2 k + 1) \pi}{n} \]
our second formula becomes
\[ x^n + 2 x^n + 1 = 0, \text{ or } (x^n + 1)^2 = 0; \]
because \( \text{cof.} \frac{(2 k + 1) \pi}{n} = -1 \). Consequently, the equa-

don's Theory of Numbers, Bonneycastle's Algebra, and our article Polygon.

Reciprocal Figures, in Geometry, are such as have the antecedents and consequents of the same ratio in both figures. See Plate XII. Geom. fig. 2. Here
\[ A : B :: C : D, \text{ or, } \]
\[ 12 : 4 :: 9 : 3 \]

That
That is, as much longer as the side A, in the first rectangle, is than the side D of the second rectangle; so much deeper is the side C in the second rectangle, than the side D in the first; and, consequently, the length of one is compensated by the depth of the other.

Also, as the side A is \( \frac{1}{2} \) longer than the side C, so the side B is \( \frac{1}{2} \) longer than D: wherefore the rectangles must be equal.

This is the foundation of that Catholic theorem: that the rectangle of the extremes must always be equal to that of the means; and, consequently, the reason of the rule of three, or golden rule.

For, suppose there were given any three numbers, or quantities, geometrically proportional, as A, B, and C; and, that it were required to find a fourth, D, proportional to them: since \( A : B :: C : D \), therefore \( A D = B C \), and,

\[
D = \frac{B C}{A}
\]

that is, the fourth term is equal to the quotient of the second, multiplied by the third term, divided by the first.

Or, thus in numbers: suppose given 12, 4, and 9, required a fourth proportional. Now as 12 : 4 :: 9 : Q.

But 12 Q = 4 \times 9 = 36. Therefore \( Q = \frac{36}{12} = 3 \),

by dividing both sides by 12.

And hence it follows, that if any two triangles, parallelograms, prisms, parallelepipeds, pyramids, cones, or cylinders, have their bases and altitudes reciprocally proportional, those two figures or solids are equal to one another; and, vice versa, if they are equal, their bases and altitudes are reciprocally proportional.

**Reciprocal Proportion**, is that in which the fourth is less than the second by so much as the third is greater than the first; and vice versa. See **Proportion**.

This is the foundation of the inverse, or indirect rule of three. Thus, 4 : 10 :: 8 : 6.

Great use is made of this reciprocal proportion, by Sir Isaac Newton, and others, in demonstrating the laws of motion.

**Reciprocally Theorem.** See **Theorem**.

**Reciprocally**, the property of being reciprocal; thus we say, that in bodies of the same weight, the density is reciprocally as the magnitude; *viz.*, the greater the magnitude the less the density; and the less the magnitude the greater the density; so again, the space being the same, the velocity is reciprocally as the time, and the contrary.

**Recipocity.** The law of reciprocity is a term used by Legendre, in his "Theorie des Nombres," to denote a reciprocal law, which has place between prime numbers of different forms; which is this: that \( m \) and \( n \) being prime odd numbers,

\[
\frac{n-1}{2} \div m = \frac{n-1}{2} \div n
\]

provided \( m \) and \( n \) are not both of the form \( 4x - 1 \), and if they are both of this form, then

\[
\frac{n-1}{2} \div n = - \frac{n-1}{2} \div m
\]

or they will have only contrary signs.

**Recission, in Law.** See **Ademption**.

**Recit**, Fr., a generical term in music, for what is sung by a single voice. It is likewise applicable to instruments; as, recit de baie, recit de hautbois; a solo part for the violoncello or hautbois. Indeed *recit* in French, seems synonymous with the word *sol* in Italian, to whatever vocal or instrumental part it is applied, in opposition to *tutti*, or chorus, in which the whole band is employed.

*Recit* in France is not only a technical term in music, but in the drama, where, at the opening of a tragedy, or subsequent to an event, it implies an account, a narration, the recital of an event. In the French and Italian tragedies, in imitation of the Greeks, battles and murders are always recited, but never transacted on the stage.

**Recital, in Law**, the rehearsal, or making mention, in a deed or writing, of something which has been done before.

A recital is not conclusive, because it is no direct affirmation; and by recited recitals in a true deed, men might make what titles they pleased, since false recitals are not punishable. If a person, by deed of alienation, recite that he is possessed of an interest in certain lands, and assign it over by the deed, and become bound by bond to perform all the agreements in the deed; if he is not possessed of such interest, the condition is broken; and though a recital of itself is nothing, yet being joined and considered with the rest of the deed, it is material. And where it is but a recital, that before the indenture the parties were agreed to do such a thing, it is a covenant, and the deed itself confirms it. The recital of one lease in another, is not a sufficient proof that there was such a lease as is recited. But the recital of a lease in a deed of release, is good evidence of a lease against the releasor, and those who claim under him. A new reversionary lease shall commence from the delivery, where an old lease is recited, and there is none, &c. A recites that he hath nothing in such lands, and in truth he has an estate there, and makes a lease to B. for years; the recital is void, and the lease good. In this case, if the recital were true, the lease would not bind.

**Recitation, the act of reciting, or delivering a discourse, either in the way of narration, rehearsal, declamation, or the like.**

**Recitativo, Itat., Recitative.** The Cruden Dictionary gives no more early authority for the use of this word, as a musical term, than that of Batiffa Doni, de Prez, Mof. Vetere, published in 1647; who defines it, "a musical composition in an andante or plain style, different from air; it is used in narrative poetry, in imitation of recitation on the stage."

Rousleau's definition is more full and clear. He terms it a discourse, or speech, in musical and harmonical tones. It is a melody nearly approaching to common speech; a musical declamation, in which the musician ought to imitate, as much as possible, the inflexions of voice in declaiming. This melody is called recitative, because it resembles a narration, a recital; and is used in the dialogue of musical dramas."

We have presented our readers, under the article *Opera*, with extracts from the prefaces of the poets and composers by whom recitative was invented, as well as from contemporary writers, who thought its origin of sufficient importance to be recorded.

Giovanni Batiffa Doni, about the middle of the 17th century, (Op. Omn. tom. ii. in Firenze, 1763, folio,) a learned and elegant writer on music, though extremely warped in his judgment by a predilection for the music of the ancients, in a dissertation on the Origin of Stage-singing, during his own time, gives so curious and instructive an account of the first operas that were performed at Florence, that we shall translate a part of it.

"Some kind of cantilena, or melody, has been introduced
in dramatic representations, at all times, either in the form of intermezzi (interludes), between the acts; or, occasionally, in the body and business of the piece. But it is still fresh in the memory of every one, when the whole drama was first set to music, and sung from the beginning to the end."

The revival of theatrical music was brought about by the invention of recitative, as we have already itated in our article Opera.

"The beginning of this century (1600) was the era of musical recitation on the public stage at Florence, though it had been used there in several private exhibitions before. There refided in that city, during these times, signor Gio. Bardi de' Conti di Vernio, who was afterwards called to the service of pope Clement VIII., by whom he was tenderly beloved, and made his maestro di camera. This most accomplished nobleman was particularly attached to the study of antiquity, and to the theory and practice of music, to which he had applied himself for many years so closely, that he became, for the time in which he lived, a correct and good composer. His house was the constant rendezvous of all persons of genius, and a kind of flourishing academy, where the young nobility often assembled to pass their leisure hours in laudable exercises and learned discourse; but particularly on musical subjects, when it was the wish of all the company to recover that art of which the ancients related such wonders, as well as other noble inventions, which had been ruined by the irritations of barbarians.

"During these discouuns, it was universally allowed that as modern music was extremely deficient in grace, and the expression of words, it became necessary, in order to obviate these objections, that some other species of cantilenas, or melody, should be tried, by which the words should not be rendered unintelligible, nor the verse destroyed."

Euridice was the first musical drama after the invention of recitative. It was written by Ottavio Rinuccini, set by Jacopo Peri, and performed at Florence in 1600, on occasion of the marriage of Mary of Medicis with Henry IV. of France. The poem and the music were published separately the same year. The poet, in his dedication to the queen of France, says, "It is generally imagined that the tragedies of the ancient Greeks and Romans were entirely sung; but this noble kind of singing had not till now been revived, or even attempted, to my knowledge, by any one; and I used to think, that the inferiority of our music to that of the ancient was the cause; till hearing the compositions of Jacopo Peri to the fable of Daphne, I wholly changed my opinion. This drama, written merely as an experiment, pleased so much, that I was encouraged to produce Euridice, which was honoured with full more applause, when sung to the music of the fame composer Jacopo Peri, who with wonderful art, unknown before, had merited the favour and protection of the grand duke our sovereign, it was exhibited in a most magnificent manner at the mptials of your majesty, in the presence of the cardinal legate, and innumerable princes and nobles of Italy and France."

Such is the abridged history of recitative. The only printed copy of the music to this primitive opera was in the library of the marchese Rinuccini, a descendant of the poet at Florence: in examining and making extracts from which, we observed that it was printed in score, and barred; two very uncommon circumstances at the time of its publication; that the recitative seemed to have been not only the model of subsequeut composers of early Italian operas, but of the French operas composed by Lulli, a native of Florence; and that the time was as frequently changed as in the old French operas.

The confusion arising from all the parts singinf different words at the fame time, together with some other circumstances, mentioned under Opera, account for the necessity of a recitative, or a musica parlante, a speaking music, and for solo singing in general on the stage: besides, poetry was injured, and rendered unintelligible in fugues, canons, and in choruses, full of imitations and contrivances, all unfit for narration and dialogue.

To describe the characteristic difference of recitative from air, and common speech; it is not air, as no time is kept; it is not speech, as every inflexion of voice is in tune with some one note of the instrument by which it is accompanied; and as to the length or shortness of the notes that are written, the companion watches for the accents or termination of phrases, or lines in the verse, to give the chord to which the note that is sung belongs.

It is sometimes accompanied by the orchestra with ritornelli, or interlithial symphonies; but then a regular time must be kept. This only happens in solemn scenes of dignity or diffirets, and in foleoques.

No flats or sharps are placed at the clef in recitative: these are all regarded as accidental; nor is Italian recitative ever confined to any one key.

After recitative was found, it was long ere any thing like an air appeared in these musical dramas. (See Opera, Air, Motivo, and Measure.) Roussel has treated the article recitative at large, with great intelligence and good taste.

Recitative Style, is the way of writing accommodated to this sort of music.

RECV, LA, in Geography, a well-fortified town of Brail, in the jurisdiction of Fernambuco.

RECKENITZ, a river which separates the duchy of Mecklenburg from Pomerania, and runs into a lake, which communicates with the Baltic near Ribnitz.

RECKHEIM, or REKUM, a town of France, in the department of the Lower Meuse, which gives name to a county, situated on the W. side of the Meuse, and surrounded by the bishopric of Liege; 7 miles N. of Maeftricht.

RECKLING, in Rural Economy, a provincial word, signifying the last of the farrow or brood of pigs, poultry, or other sorts of domestic birds.

RECKLINGHAUSEN, in Geography, a town of Germany, fortified by a castle, and capital of a county of the same name, which is situated between the bishopric of Munster, the duchy of Cleves, and the county of Mark; 16 miles S.S.W. of Munster.

RECKON, in Rural Economy, a term sometimes applied to a pair of pot-hooks of a certain make, occasionally employed in dragging wells, ponds, &c.

RECKONING, in Navigation, the art of estimating the quantity of a ship's way; or of the distance run between one place and another.

Or, more generally, a ship's reckoning is that account, by which at any time it may be known where the ship is, and on what course or courses she is to steer to gain her port. See Log-Board, Log-Book, and Journal.

This is usually performed by means of the log-line; the manner of applying which, see under its proper article, Log-Line.

Yet this is liable to great irregularities. Vitruvius advises an axis to be passed through the sides of the ship, with two large heads projecting out of the ship, in which are to be included wheels touching the water, by whose revolution the space passed over in any given time may be measured. The fame has since been recommended by Stella; but
but there are few who have written of navigation, that have not shown the insufficiency of this method.

Reckoning, Dead. See Dead Reckoning.

Reckson, in Geography, a town of Bengal; 6 miles E. of Calcutta.

Reclaiming, or Reclaiming, in our Ancient Customs, the action of a lord purifying, profaning, and reclaiming his vassals, who had gone to live in another place, without his permission.

Reclaiming is also used in a similar sense, for the demanding of a person or thing to be delivered up, or surrendered, to the prince or state it properly belongs to; when, by any irregular means, it has come into the possession of another.

Reclaiming, in Falconry, is the calling of a hawk, or bird of prey, back to the fist.

The sparrow-hawk, goshawk, etc. are reclaimed with the voice; the falcon only by cutting the line. So that the term luring, with regard to the falcon, is more proper than reclaiming.

The partridge is also said to reclaim her young ones, when she calls them together upon their scuttering too much from her.

Reclaiming is also used for taming animals that are wild by nature.

Reclaiming, in a monastic fen. See Religious.

Reclaiming Lands, in Agriculture, the business of re-flowering and bringing them into a state of cultivation and improvement. There are various kinds and states of land, which admit of this sort of amelioration and improvement; as among the wet forts, all those of the bay or estuary description, which are washed and occasionally covered by the sea or other waters; different descriptions of fen lands, and those of the more firm marshy nature, and those in more interior situations, which are of a loose swampy or watery quality, as marshes and boggy grounds. And among those of the more dry, hard, white, and wild descriptions; all the varieties of the rough silly forts of unimproved lands; the many different kinds of rough woody grounds; and the numerous forts of moory lands, as well as other varieties, which are now and then to be met with in particular circumstances and situations.

The first of the wet or watery forts of land, noticed above, are far from being always ready, or in a ripe state for admitting improvement of this nature; yet in different situations and circumstances, they occasionally permit of its being accomplished, without any great difficulty or trouble. See Embankment, and Embarking against the Sea.

The fenny and marshy lands, where, in the former, they are wholly or only in a partial manner overgrown by ulelefs aquatic plants; and in the latter, are become too firm as to bear the pattering flock, and to afford nutritious herbage for their growth and support, but are notwithstanding full liable to be overflowed by high tides, or land floods; are, of course, capable of very great improvement in the above ways, as well as by many other means. See Fen, Fenney Land, Marsh Land, and Salt Marsh.

These forts of watery lands are not incident to the flat bays and inlets of the sea-coasts, or the mouths of the large rivers, in a particular manner; but are met with in the more inland situations of the country, accompanying the larger rivers and waters in the more central parts of the kingdom: consequently such forts of improvement must be very extensive in their nature, and of very great importance to the nation.

The other kinds of swampy watery lands, which are liable to be covered with that fluid during wet seasons; those on the sides of lakes and ponds; the marshes which are choked and grown up with aquatic vegetables, lo as to have some sort of hardish crust formed upon them; and the soft boggy lands, formed in somewhat similar ways, are all capable of allowing great improvement, by suitable draining, and other methods of management. See Spring and Surface Draining, Swamp, Bog, and Morass.

Lands of the above kinds are mostly met with on the lower slopes, or at the feet of hilly grounds; being caused by the stagnation of water in their internal parts, which has the effect of chilling and rendering them too moister for the production of a nutritious and useful herbage, as well as of promoting the growth of coarse plants of the aquatic nature, though their situations may occasionally have some degree of relative height.

There are many valuable tracts of land of these kinds, in many different parts of the island, which have been already reclaimed by these methods of proceeding; which should have the effect of stimulating the owners of such lands in other places, where they still remain unimproved, to exert themselves in getting them reclaimed.

Among the more dry kinds of unreclaimed lands, the fir, or those of a rough, itony, waile quality, are all those in the valleys of hilly or mountainous tracts, on the skirts or lower parts of mountainous heights, and the rough itony lands, fit for cultivation, in other situations. They are the most readily reclaimed and improved, in the least hilly forts of lands and situations. In some cases, where the surfaces of the ground were in a great measure covered by large rocks and stones of great sizes, very hard in their qualities, and of scarcely any value, the lands have been reclaimed, and brought into an arable state, and let for high rents: the stones which were removed paying, in a great degree, the expenses of the labour; they being exported and sold as paving-stones, and for other uses to the metropolis. And though this cannot always be done, it shews what is capable of being performed by industry and perseverance; and that, where surface stones can be turned to useful purposes, the most rugged and barren lands may be reclaimed with advantage, under proper modes of management. In such instances, instead of leaving the surfaces of the grounds in worse states than they were before, by being taken up with pits, and heaps of ulelefs rubbish, which buried the better moulds, as is common in working superficial quarries, the pits and other hollows were levelled, and filled up to some height, with the coarse and rubbish materials produced in the course of the works, and the finer mould from other parts thrown back upon the above sub-foil materials, so as to form an even top-foil; the larger spaces of the ground being trenched over to a good depth, leaving the belt foil on the surface. It is thus finished, that by following similar easy methods of management, in carrying on other undertakings of the same kind, lands of a value in proportion to that of the materials which are removed, may commonly be created, without incurring any very great expense. Hence it is thought to believe those who have the direction and management of landed estates, that comprehend grounds of these forts, to examine and consider well whether the itony materials which they contain, and encumber their surfaces, cannot be turned or converted to some profitable purpose, by the means of roads, iron railways, canals, or some other easy mode of conveyance for such heavy substances.

It must be noticed, however, that the method of levelling and trenching over the lands by the spade, in such circumstances, can only be practised in a very few cases, where labour is particularly cheap.

There is another description of itony lands, of a much
lefs formidable nature, which frequently stands in need of being reclaimed, and in which the surface is left encumbered than the interior parts of the soil. In these cases, the interrupting materials are rather large stones than rocks, though the latter may sometimes in part form them. The means which are best suited to the bringing of these into a profit-
able state of cultivation, are to be found in the more northern parts of the island, in the practice and exertions of particular spirited individuals. The plan of the improvement is perfectly simple, but it is expensive in its performance; the whole of the land being terminated over by means of the spade, to a proper depth, as from one to two feet. The stones which are not wanted for use are thrown into pits, and the hollow parts, to contribute to their being made level, are sometimes into the deep trenches formed in digging, being first covered over with the work of the earthy materials, upon which the better moulds and turfy sub-
stance, which are filled in the work, are spread out as a foil, by which the whole is rendered very suitable for agricultural purposes.

The soil of reclaiming lands in this way depends, in some measure, on the cult of surface in the lands, the nature of the interrupting matters, and the depth of the earthy sub-
stances to be removed, in razing a sufficiency of mould for forming the surface foil: but from five to twenty pounds the acre may be considered as the limits of the charges.

And this, it is supposed, leaves an ample profit in the sale of such lands, or otherwise, in these situations where tythes are not taken, and where the rates and taxes are so very few and trifling, and where labour and living is so cheap. It can now, however, be done in this manner in but few instances, as has been already noticed.

It is, notwithstanding, believed that there are very many lands, not only in these northern parts, but in England and Wales, that would more than repay the expenses of this spirited mode of improvement. It may be remarked, that where the stones are very large, or where fragments of rocks are met with, in these undertakings, they may be got rid of either by blasting, or rendering their upper parts, or by linking them in the soil, so as to allow the plough to pass over them with safety.

The former method is more suited to the loft forts of stones; the latter to those of the harder kinds.

Such rocky grounds as are common in hilly and moun-
tainous situations, which, on account of their climate, and the compact nature of the rocky materials, as well as their quantity, are incapable of being cleared as corn-lands, or so as to admit the plough, may often be reclaimed and improved as pasture lands for sheep, &c. or sometimes as hay lands. The plan of proceeding, in these cases, is that of removing the flinty matter from the surface, and allowing it entirely to the growth of grassy herbage: the means of accomplishing which is similar to those already noticed, but the soil considerably left: the main attention here being merely the smoothing of the surface ground, for the pur-
poses of pasturing or mowing; but the more the flinty sub-
stances are covered with good earthy mould, the better and greater will be the quantity of produce. See Til-

There are many rough woody tracts of ground, of the shrubry or other kinds, which may be cleared and reclaimed with vail advantage to their proprietors, as well as the community in general, as corn-lands, or for other uses. The most usual method of accomplishing this sort of improvement has been to dig out the whole of the roots, whether of low woods or timber woods, at the time of enning the crops, so as to admit the plough immediately. In perform-
ing this in this way, however, where the floors are of the timber kind, numerous and large, deep breaking of the ground is often necessary, which is laborious and expensive; and rotten wood, mould, leaves, and other surface matters, are apt to be left in mixture with the fertile or poisonous sub-flora. As lands, cleared and reclaimed in this manner, have been known to remain in a rare unprofitable condition, for several years, though lined, dunged, and raised in sharp ridges, in order to its acceleration. This improper practice has consequently been highly disadvantageous, injurious, and ruinous, and thrown much difficulty and interruption in the way of clearing and reclaiming such waste lands for the growth of corn, however suit-
able they may be for the purpose in the nature of their soils and situations, thereby tending to propagate and support the notion, that such finds of land will not repay the ex-

ences and trouble of being improved.

But from attending to what has naturally happened to the cleared parts of wood-lands, it will be seen that a depth of fertile mould, reposing on fertile sub-flora, form a reg-
ular foil and sub-foil, which are free from the roots of trees, ready to receive the plough, and afford corn crops in due succession. This is supposed to take place somewhat in this way. The trees having been suffered to become decayed, or more properly cut down in due season, and the brush or underwood cut and cleared away from time to time by the occupiers, while such commons or other places were fully or too much crossed with cattle and sheep, the young shoots were of course browned off and nibbled away quite to the stumps, consequently weakened, and at length totally destroyed. The roots and other parts soon followed this course, and pulled into a state of vegetable mould, increa-

ing and enriching the soil at the same time. Nay, this may, in the natural state, it is supposed, be, in some mea-
sure, effected alone by the grazing animals, as it is essential to their existence.

This natural process, however, afforded in this way, is slow, requiring a length of time for its completion; yet by proper means of art, well applied, it may be accomplished in a few years; the larger roots being extracted from the ground, instead of waiting for their reduction by a slow de-
cay, without any unnecessary disfigurement of the sub-foil;
and then filling in the pits by the roughhewings of the natural surface; by which means the cleared ground will be smoothed and made fit in due time for being cultivated. Where the surface is much incumbered with leaves and rotten woody matters, they are to be raked up, and put into heaps to decay; or they may be burnt, and the ashes spread out over the surface of the land. Proper draining and fur-
ther levelling mull likewise take place, where necessi-

ty; as well as harrowing or hacking the surface aford, so as to sow it with proper grass seeds; again raking off any rubbithat may arise, and then rolling the whole quite smooth for mowing. It should be rolled hard, especially with the wheeps, mowing off occasionally any woody shoots that may be permitted to arise; keeping the whole in the state of clofe pal-
turage, until the smaller roots, which were left, be so de-
cayed as to become obedient to the plough-share. At this period, but not before, such pasture ground may be broken up for grain crops in proper succession.

The process might be hastened by the use of lime, or other calcareous matters in union with the vegetable sub-
flora which were removed, as they would be sooner dif-

olved or reduced, and the compost be more rich. And by spreading them out on the land a similar effect might be produced, and a finer sort of herbage be encouraged, which would cause a clover bite, and sooner bring the land into a
more thick set rate of sward, which is the prolific matrix for corn crops.

The really necessary expense of reclaiming and bringing these kinds of wooded lands into a state of cultivation, by these means, is inconceivable, particularly where fuel is dear. Where the timber wood is properly cut down by the axe, and the underwood taken off rather below the surface, the larger roots, and the stubs which are left, will, in some instances, more than repay the colt of the clearing and levelling the surface. And the other expenses will be repaid by the immediate production of a fallow ground, the value of which is constantly increasing without any further charge, until it may probably be worth two or three times what the lands were while they were in the woody condition.

In cafes where fuel is cheap, and particularly when the timber wood is rapidly fallen, as in the barking leafton, they may be cut off by the level way with the surface of the land; the stubs, and large superficial roots being after that carefully disburied to fome inches within the ground, &o as to prevent their throwing out shoots to injure the surface and keep the roots alive. In this way the stubs will be fo decayed in a few years as to be capable of being removed with little trouble or expense. See Tillage.

In clearing and reclaiming moory lands where they are too wet, the first step is that of properly draining them; they are afterwards brought into cultivation and to their full value by other means, such as in large undertakings, by suitable divisions of the lands into fields proper for the farm or farms to which they are to be laid, and so ditched as that the surface water may be effectually taken off, without having deep, open, expensive troublesome drains in other parts; the surface of each field being adjusted in such a manner as to shoot off the rain water into the intersecting ditches, in order to prevent injury from happening, in that way, so as to impede the cultivation for any length of time.

As the surfaces of these kinds of land are mostly rugged and uneven, as well as of a loofe spongy texture, which unfit them for the tillage processes, without previous affilintance from hand labour; where the moory earth, or vegetable mould, is deep, and refes to the surface uncovered by fossiliferous matters, some length of time is requisite to bring it to that solidity and firmness of texture which is suited to the common arable purposes. Hence the general principle of improving deep moory lands, where there is no fossiliferous covering, is supposed to be the fame as that advised for bringing woodlands into cultivation; namely, that of converting them to a profitable state of herbage, before corn crops are attempted to be produced.

The processes must be guided and regulated by the nature and situation of the tract to be improved. Where the surface is very irregular, full of inequalities, and of an abrupt nature, it must first be adjusted so as to admit the means of tillage when they can be properly had recourse to, and for carrying away the surface waters in the manner already noticed. Then to pare off the leffer hillocks and ridings, as the stubs and hallocks which were formed during its wet state, and more or less of its general surface, so as to remove the coarse plants and flate mould which occupy it, and thereby produce a freshfines in the whole.

In dry leaflons, when the surface has sufficient firmness to bear the tread of animals, the paring may be done by the plough for that purpose, but in other cafes by the breakfast plough or paring-fpade. When the surface has been cut over in this manner, and any part has the appearance of being too wet, as may be judged of by the colour of the mould, in some degree, covered drains are to be formed in such places, which may commonly be made in a cheap and durable manner by the firm fibrous tufts collected from the surface. The root of the roots and mould which were pared off should be burnt, and their ashes spread evenly over the surface, being immediately raked or harrowed into the foil. At this period of the improvement almost any kind of fossiliferous material can be thrown over the ashes at a little expense; and a full quantity of different grasses seeds be covered in with it; leaving the surface to take on a sward without any further trouble or outlay of money.

Afterwards the grasy herbage is to be kept closely fed down when the weather will permit, first by sheep and then by heavier forts of flock, until the surface becomes firm and the foil is well bound together by the fibrous roots of the herbage, fo as to be capable of affording corn crops in proper succession.

It has been objected to this summary mode of bringing the land into the state of herbage, that there are no immediate gros returns for the money laid out in reclaiming and bringing it into the cultivating state. But although corn cannot be raised on such raw loose-textured forts of land at first, potatoes are found to answer well, and rape with still more advantage in its culture, the labour attending it, and the profit which it affords. See Moor, Moory Land, Spring and Surface Draining, &c. See also the Invernesshire Agricultural Report.

The reclaiming and bringing lands of these several different descriptions into a state of cultivation and improvement is evidently a work of very great importance, particularly in a country where the population is increasing too numerous for the produce, as by such means the extent of agricultural territory may be jujlly faid to be increafed. Extensive improvements of these kinds have lately taken place in Cornwall, and some other southern districts.

RECLAIMING PLANTATIONS AND TIMBER WOODS, IN RURAL ECONOMY, the reafoning of such as have grown into a wild, neglected, and improper state from some fort of mismanagement, or want of attention. The cafes which have a tendency to produce this effect are very numerous, and have been the means of vast individual as well as national loss. One material and very frequent cause is the neglect of their boundary fences; another is the mitaken notion of its being the best practice to leave them entirely to nature after they are once properly planted; a third is the very abuful suppression, that nothing should be done to them for a length of time after planting, in the way of rendering the trees more thin among themselves, or in their branches; and lastly, an universal carelessness and disregard of them, frequently from the narrow conception of expense being incurred without the chance of any immediate return of profit. It is, on the whole, much too common to take great care in first forming the plantations, without ever thinking or taking any fort of interest in their after-management. But the benefit is by no means accomplished in the simple act or operation of planting out the trees. Good examples of this kind of management are indeed few, but they occasionally exit, and much has been written on the matter, so that information may be readily obtained. And there is every inducement to get it; as well prepared, inclosed, planted, cultivated and managed plantations, will far outgrow others that have existed for a much longer time, but have been otherwise treated, often affording more than woods of three times their length of standing.

In directing the proper management in all cafes of this nature, some attention must be paid to the particular kinds of the plantation which they may be, in the first place; after which, the means of reducing them to their appropriate states, or to some other in the most easy and convenient manner,
manner, may be taken into consideration. It may often happen that their proper originally intended flates cannot be attempted, but that which has been gradually acquired must be promoted. With a view to the accomplishment of those intentions, plantations may be considered as consisting either of hard woods only, or of evergreen or resinous trees only, or of both these sorts of trees in mixture.

In the first of these kinds, or those which are composed solely of the hard-wooded sorts of trees and plants, where they are to be brought into the flate of woods, as timber trees and under-growths, and the latter to be used only as fuel, the good trees of such kinds are suitable to the soil, and the probable demand of the vicinity and other parts, should be fixed upon, and left as standard trees; the whole of the others being cut over by the surface of the ground, so that they may become tools for supplying the under-growths. When this has been performed, the ground, where necessary, should be dug, hoed, or trenched over, as circumstances may direct; but where the trees and under woods have been much crowded, these kinds of work will seldom be required. However, if, instead of the common underwood, oak be required, then after pitching upon the most proper and suitable standard trees for remaining, the whole of the rest are to be taken up by the roots, the land dug over, and acorns planted out upon it; which, when they are grown up, must be kept clean and free from weeds for some years, in order to promote their healthy growths and rife to the flate of young trees.

Where the whole is to be reduced to the flate of cope wood for fuel only, the belt way is to cut over every part by the surface of the ground; and when for bark, to root out the whole, only relerving the oaks, and planting with acorns as already noticed.

In the grove forms to be produced, the most suitable and appropriate trees are to be left at proper distances, and the whole of the remainder taken out by the roots; after which the ground should have the proper culture, until the trees are incapable of being injured by cattle flocks; at which time the whole may be laid down with natural grats feeds.

In the second sorts of plantations, where they have remained, after planting, without being in any way thinned, for a great many years, they are often, in a great measure, incapable of being remedied, as they are, for the most part, so overpowered by each other, that their growth is suffocated; wherever any thinning takes place, the trees all round are destroyed. In these cases it is the advice of some to have the whole grubbed up by the roots and replanted, after the ground has been properly prepared by fallowing and repeated corn crops. But as there may sometimes be much lost in this way, it may be proper to try the cautious thinning of them, which should be done during the latter summer months in a careful manner, as succefs has occasionally attended this method.

With natural plantations of this kind under twenty years' growth, and artificial ones under ten, much advantage has been gained by suitable cautious thinning and retrenching. In all these cases there is no necellity whatever for the cultivation of the ground, as the trees suffer few or no plants to rife below them, and besides, injury may be done to their superficial roots.

The management in the lat or mixed kinds of plantations, where the evergreen trees are in such proportions as not to admit of either of the above modes, is to reduce them to the grove plan only, or to this in some parts and the wood kind in others; the modes of accomplishing both of which have been already laid down. However, in each of these methods, it will frequently happen that the tree or trees which are the most advantageous and desirable in the parts where the plantations exist, are either very deficient, or wholly wanting. In all such instances it is probably the best and most beneficial practice to grub up nearly the whole of such trees, and replant the ground with the proper sort or sorts; care being taken to leave such a number of the old trees, either in a scattered manner, or in narrow flipes and screens, for sheltering and protecting the young trees, plants, and feeds, which have been put in, planted, or sown. See Plantation and Wood.

It may be noticed that in reclaiming all kinds of wild and neglected plantations in lands which are inclined to the retention of moisture; the first thing which is necessary is invariably that of the removal of the stagnant watetuses, as where this is not properly performed, the other operations will be of but little avail, however well they may be executed. In many extensive tracts of this nature, the injury which is sustained by this sort of neglect is fiercely to be calculated. There are many thousands of acres, in different situations in this country, which would by this means alone be brought to twenty times and more their present value. And as this sort of work in such cases can, for the most part, be accomplished by open cuts or gutters alone, at a very trifling expense in comparison of that for arable and some other sorts of land, it should never be neglected where good management is in the least degree attended to. See Surface and Subterraneous Draining.

It is a material point in reclaiming all these sorts of plantations and timber woods, to keep the surrounding ditches and fences well up and in a proper safe flate, as large tracts are often completely ruined in a very short time by inattention in this respect, from the cropping, rubbish, and defloration in other ways produced by the entrance of cattle of different kinds into them. There is hardly any thing so injurious to the more young timber plantations as cattle being suffered to get into them. See Fence.

The retrenching of old ill-managed plantations of these kinds should constantly be done in a very gradual manner, having due regard to their length of standing, the nature of the trees, the quality of the land, the situation and exposure, as well as some other points. Their outside parts are in general to be left more thick and close, than those which are more in the interior, and the parts of the soil which are of a bad thin quality, should be left less thick of trees and plants than where it is of greater depth and richness. And open exposures should be kept more thick and close than where they are more warm and sheltered.

In retrenching the branches of the different trees, the work should be performed according to the length of time the trees have been growing, their particular growths and sizes, the difference of kind, and the uses, purposes, and intentions for which their wood or other parts are designated. It is always proper to stop rather short, than to carry it to an extreme, as there is sometimes danger in the latter case. See Pruning.

It is always necessary and essential to reclaim these old wild sorts of plantations as soon as possible, as the forming of new tracts of this kind chiefly benefit poltery, while the ameliorating and improving of the other, by these means, are an immediate and direct gain to the present proprietors, of very great national importance at the present time, and which would otherwise be complete losses to both.

No sorts of woods of the timber kind should indeed ever be suffered to remain any great length of time without being properly looked over and put into such flates as that they may go on in the most beneficial and profitable manner, as
where they are in any way or by any means restricted or impeded in their growths, there is a constant and continual loss taking place, and the ultimate disadvantage is prodigiously great, as the timber never becomes either so good or in such quantity; of course it is of inferior value in both respects, which makes a difference of much consequence to the proprietors as well as to the nation at large. See Wood.

RECLINATION of a Plane, in Dialling, the number of degrees which a dial-plane leans backwards, from an exactly upright or vertical plane, i.e., from the zenith.

The reclination is easily found, by means of a ruler, and a quadrant; for having drawn an horizontal line on the plane by a level or quadrant, and to it another line at right angles, apply a ruler, so that one end of it may hang over, or reach beyond the plane; then will a quadrant, applied to the under edge of the ruler, shew the degrees and minutes of the plane’s reclination; counting from that side of the quadrant that is contigous to the edge of the ruler.

RECLINATUM Folium, in Botany, a leaf whose point is curved downwards, below the level of the base. See Leaf.

RECLINATUS CAULIS, a reclined stem, is bent towards the earth, as in many species of Ficus, Salis, Rubus, &c.

RECLINER, or RECLINING Dial, is a dial whose plane reclines from the perpendicular; i.e., leans from you when you look at it before it.

When this reclination is equal to the height of the pole, the dial is said to be equinoctial. See Dial.

RECLINER, Declining, or Declining reclining dial, is a dial which neither stands perpendicularly, nor opposite to one of the cardinal points. See Dial.

RECLUSE, among Religious, a person close shut up in a very narrow cell of an hermitage, or other religious house; and cut off, not only from all conversation with the world, but even with the house. The word is chiefly used for such as thus imprison themselves out of devotion, to do penance. It is sometimes also applied to incontinent wives, whom their husbands procure to be thus kept in a perpetual prison in some convent.

Recluses were anciently very numerous; they were then a kind of solitaries who shut themselves up in some little cell, with a vow never to stir out of it.

None were admitted to this oath until they had given sufficient proofs of their abstinence, and had leave from the bishop, or the abbot of the monastery where they were shut up; for the cells of the recluses were always to join to some monastery.

The prelate’s permission being obtained, they were tried for a year in the monastery; out of which, during that time, they never stirred.

They were then admitted to their vow of stability in the church before the bishop; which being done, and the recluse having entered his little cell, the bishop fett his seal on the door.

The cell was to be very small, and very exactly closed. The recluse was to have every thing within it necessary to life; and even, if he were a priest, an oratory consecrated by the bishop, with a window which looked into the church, through which he might make his offerings at the mass, hear the singing, sing himself with the community, and answer those who talked to him. But this window was to have curtains before it, both within and without; so that the recluse might neither see, nor be seen.

Indeed he was allowed a little garden in his reclusion, to plant a few herbs, and take fresh air; adjoining to his cell was that of his disciples, which he was very rarely without; with a window, through which they served him with necessaries, and received his instructions.

When it was judged proper to have two or three recluses together, their cells were made contiguous to each other with windows of communication; if any woman would consult them, or confess to them, it was to be in the church, and in the face of all the world.

Where there were two or three recluses together, they were never to hold any conference, but on spiritual matters, and to confess to each other; where there was but one, he was to confess and examine himself.

If the recluse fell sick, his door was opened for people to come in and afflitt him; but he was not allowed to stir out on any pretence whatever.

These articles are extracted from the rule, compiled for the recluses, by Grimaiac, a priest in the ninth century.

There were also women recluses, who led the same life, in proportion. St. Vivara died a recluse at St. Gall, and was there martyred by the Hungarians in 825.

RECLUSION, the state of a recluse; or the cell and other appurtenances of it.

F. Helyot gives a particular account of the ceremonies practised in the reclusion of a woman, in that of mother de Cambray, inftitutrix of the order of the representation of Notre Dame. A cell being built for her in 1625, adjoining to the church of St. Andrew, in Tournay, the bishop waited for her early in the morning at the church-door. Upon her arrival, proliferating herself at the feet of that prelate, he gave her his benediction; conducted her to the grand altar; and there blessing a mantle, veil, and feapular, he put them on her, and gave her a new name.

Having here made her vow, and the bishop having arranged the people in praise of the new recluse, he conducted her proceffionally to her reclusion; the clergy all singing Veni, fpona Chrifi, &c.

Here the bishop, blessing her afresh, consecrated the reclusion, and shut her up in perpetual confinement.

RECOGNISANCE. See Recognizance.

RECOGNITION. Recognizatio, denotes an acknowledgment. The word is particularly used in our law-books, for the title of the first chapter of the Statute of Rome, I Jac. I. by which the parliament acknowledged the crown of England, after the death of queen Elizabeth, to have rightfully descended to king James.

RECOGNITIONS of Clement, in Ecclesiastical History, a supposititious or apocryphal book, ascribed to St. Clement, but really composed by some learned and eloquent man in the second century. Rufinus, who translated the ten books of Recognitions out of Greek into Latin, in whose translation only we now have them, plainly supposes them to have been written by Clement of Rome; but that the copies, in his time, had been corrupted in some places. The first ecclesiastical writer who has mentioned this work is Origen, by whom it is cited twice; but he does not seem to have held it in high estimation. Eusebius, who is supposed to mention the Recognitions under the title of “The Acts of Peter, which made a part of them, rejects them, and owns no work for St. Clement, but his epistle to the Corinthians. Epiaphonius mentions “The Travels of Peter” as written by Clement, but corrupted by the Ebionites, so that little was left that is genuine. St. Jerome’s opinion of the works of Clement coincides with that of Eusebius. This book is, for a large part of it at least, says the learned Dr. Lardner, a fiction or romance, in which divers things concerning the Christian religion are represented in a philosophical manner, in order to render them more agreeable to the Greeks.
is called the "Circuits," or "Travels and Acts of Peter," from its subject, as it contains an account of the apostle Peter's disputes with Simon Magus, and his discourses to other people, and his miracles. It is called the "Recognition," from Clement's recognizing his father, and mother, and brethren, who had been long separated from each other.

Mr. Whiston, though he allows that this work was not written by Clement himself, supposes that it was the production of some of the heirs of Clement, and other companions of the apostles; but Dr. Lardner is of opinion, that it must be reckoned to be Clement's, or to be sufficiently supported. With regard to the age of this work, Lardner further adds, that the arguments here urged against Hætenism seem to imply, that the Christian was not yet the prevailing established religion. And the author often speaks of the power of Christians to heal diseases, and to expel demons, as if it was common in his time. That such gifts were enjoyed by many Christians in the second, and in the beginning of the third century, we are assured by Irenæus, Tertullian, Origen, and others; after which time, or however after the end of the third century, they were not so common, if they did not quite cease. Mr. Whiston's opinion of this book is, that if it be not, in some sense or other, itself a sacred book, yet it ought certainly to be esteemed in the next degree to that of the really sacred books of the New Testament. But in the opinion of many other learned men, it is a worthless piece, of little or no use. It contains, however, as Dr. Lardner observes, some excellent sentiments, and fine passages, intermixed with very great faults, for which no excuse can be made. This book contains passages of our four gospels, though it has been doubted whether he used the four, or some one gospel containing it all thefe. Its author seems to own the first epistle of St. John, and the book of the Revelation. He was also well acquainted with the book of the Acts of the Apostles; but it is not certain how far he owned it. The passages from St. Paul's epistles are not sufficient to prove, that they were esteemed by this writer to be of authority. The author does not feem, indeed, to have gone far in the examination of the apostle Paul, and on this account he made little use of his epistles, and of the Acts of the Apostles. From his hasty inferences, and injurious reflections upon St. Paul, it may be suspected, that he was a mere Ebionite; the ancients alluring us, that this sect of Christians rejected the authority of that apostle and his epistles. The author bears testimony to many principal facts of the New Testament. He gives an account of our Lord's temptation; he mentions the choice of the twelve apostles, and afterwards of other seventy-two disciples. In one place he speaks of the twelve apostles in such a manner as if he intended to exclude Paul from the honour of the apostleship, and even to deny him the character of a sufficient and faithful "preacher of Christ's word." We have also, in this book, relations of the miracles of our blessed Lord's ministry, and of his death and resurrection, and the extraordinary signs attending these events. Grabe's Preface to the Writings of St. Clement in his "Spicilegium," Coder apud Patr. A. vol. tom. ii. p. 424. Lardner's Works, vol. ii. p. 342, &c. See Clementine Homilies.

RECOGNITION, in the Drama. See DISCOVERY.

RECOGNITIONE, in the English law, is a writ to the justices of the common bench for sending a record touching a recognition, which the recognizor fuggests to have been acknowledged by force and hard dealing; that, if it appear, it may be annulled. See TRANSCRIPTIO.
along the cylinder, is to the length of the cannon diminished by the space behind the ball, as the weight of the ball is to the weight of the cannon. Let a twenty-four pounder of ten feet be 6400 pounds weight, and when the ball quits the piece, the cannon will have recoiled \( \frac{1}{3^2} \times 10 = \frac{10}{9} \) of a foot, less than half an inch.

The greater the charge, \( \text{ceteris paribus} \), the greater the rebound. By an experiment made before the Royal Society, and related in the Philosophical Transactions, it was found, that cannons, charged to a certain degree, throw the ball from right to left of their own direction; but that the cannons themselves recoil from left to right.

Some of the gentlemen of the French academy doubting the justness of the observation, M. Callini, the younger, undertook to repeat the experiment; which he did by means of a machine, as like that used in England as he could; and that tried over and over again.

The result was, that the ball, when the gun had liberty to recoil, was always thrown to the right of the point to which it was thrown when the gun was fixed without a possibility of rebounding; but then the recoil was always made in the same way, viz. to the right; and he never found that contrariety of directions between the ball and the rebound, observed in the English experiment. See Hist. Acad. R. Scienc. A. 1703, p. 120, &c.

The cause of the phenomenon seems very difficult to assign; for supposing the guns of a common make, with the touch-hole on the top, we cannot so much as guess what cause should confoundly determine the ball from right to left; unless some very material circumstances be omitted in the recital they have given us in the experiment.

Guns whose vents are a little forward in the chase recoil most. To lessen the recoil of a gun, the platforms are generally made sloping towards the embrasures of the battery. See PROJECTILES.

RECOLLÉS, a congregation of reformed Franciscans, called also friers minor de St. Francis, de l'Esprit observance. They were established about the year 1532, when some religious of the order of St. Francis being willing to keep his rule to the letter, Clement VII. gave them houses, whether they might retire, and receive such as were disposed to follow them. The same year he approved the reform; and in 1584 it was carried from Italy into France, where these religious had already been established, in the towns of Tulle in Limousin, and Murat in Auvergne. They had a convent at Paris in 1603; and since they have erected no less than a hundred and fifty in the whole kingdom, where they are divided into seven provinces.

RECOLEGE, in Geography, a town of France, in the department of the Doubs; eight miles W. of Besançon.

RECOMPOSITION, in Chemistry, the compounding of bodies from their separated parts, or principles, so as to compose the original whole again. This is extremely difficult to effect universally, but in some cases it may be done, and that so perfectly, that the recompounded body shall not be distinguishable by the senses from that which had never been separated by the fire. If the art of chemistry were perfect, we should thus be able, at least in some degree, to recompound all the bodies we divide; but this is far from being the case at present. We can by no means do this in vegetable and animal bodies, where there is a vascular structure, and therefore we are carefully to distinguish between the regeneration of organized, and that of unorganized bodies.

RECOLENTIA, in our Law Books, &c. A church is said reconciliari, to be reconciled, when it is consecrated after, having been polluted or profaned; as by the pollution of pagans, heretics, &c.

RECONCILIATION, in Penitents, in Church History, See Poenitentes.

RECONNOITRE, in War, implies to view and examine the state of things, in order to make a report of them. The word is French, signifying, literally, to know, recollect.

We say to reconnoitre the coasts, to reconnoitre a port, &c. A body of horse was sent to reconnoitre their camp, the ground, the condition of the roads, rivers, &c.

Parties ordered to reconnoitre, are to observe the country and the enemy; to remark the routes, conveniences, and inconveniences of the first; the position, march, or forces of the second. In either case, they should have an expert geographer, capable of taking plans readily; he should be the chief mounted of the whole, that in case the enemy happen to scatter the effect, he may serve his works and ideas.

All parties that go for reconnoitring only, should be but few in number; never more than twelve or twenty men. An officer, be his rank what it will, cannot decline going with so few under his command: the honour is amply made up by the importance of the expedition, frequently of the most interesting consequence, and the proper to recommend the prudence, bravery, and addresses of any officer that has the fortune to succeed.

It is previously necessary that the officer ordered on this duty should be well acquainted with the country, the roads, and the distance of the enemy. His party must consist of men of approved fidelity, part of whom should be disguised. This detachment must march off in the night. The men must have strict orders neither to smoke tobacco, make a noise, nor speak. The officer must be provided with two guides, who are to be strictly interrogated, but are to remain ignorant of the route you intend to take. A detachment of this kind should be furnished with subsistence for two or three days. The horses are to be fed every two or three leagues, for it is absolutely necessary that they should be always fresh and fit for duty. The officer will take care never to halt, but at a distance from any road, and also take every precaution to prevent his being surprized, whilst his horses are feeding, &c.

RECONNOITRE is also used at sea. To reconnoitre a vessel, a fleet, &c. is to approach near enough to examine the rate and burden of a vessel, &c. the force it may have aboard, what nation it is of, &c.

To reconnoitre a land, or shore, is to observe its situation, in order to find what land it is.

RECORD, RECENSUS, in Law, an authentic testimony of any thing in writing, contained in rolls of parchment, and prefered in a court of record. See Court, and Custom.
Records are said to be vetustatis & veritatis exigia. So early as the Conquest we find the "preteriorum memoria eventorum" reckoned up as one of the chief qualifications of those who were held to be "legibus patriae optime institutis." For it is an established rule to abide by former precedents, where the same points come again in litigation; as well to keep the scale of justice even and steady, and not liable to vary with every new judge's opinion, as also because the law in that case being solemnly declared and determined, what before was uncertain, and perhaps indifferent, is now become a permanent rule, which it is not in the breath of any subsequent judge to alter or vary from, according to his private sentiments; he being sworn to determine not according to his own private judgment, but according to the known law and custom of the land; not delegated to pronounce a new law, but to maintain and expound the old one. Yet this rule admits of exception, where the former determination is most evidently contrary to reason; much more if it be clearly contrary to the divine law. But even in such cases the subsequent judges do not pretend to make a new law, but to vindicate the old one from misrepresentation. For if it be found that the former decision is manifestly absurd or unjust, it is declared, not that such a sentence was bad law, but that it was not law, that is, that it is not the established custom of the realm, as has been erroneously determined. An act committed to writing in any of the king's courts, during the term in which it is written, is alterable, being no record; but that term once ended, and the act enrolled, it is a record, and of such credit as admits no alteration, or proof to the contrary.

It is a settled rule and maxim that nothing shall be averred against a record (see Court,) nor shall any plea, or even proof, be admitted to the contrary. (Co. Litt. 265.) And if the existence of a record be denied, it shall be tried by nothing but itself; that is, upon bare inspection whether there be any such record or no; else there would be no end of disputes. But if there appears any mistake of the clerk in making up such record, the court will direct him to amend it. Courts of record, or repositories for the public records of the kingdom, were first established by Edward I, our English Justiciar, some of which are more ancient than the reign of his father, and those were by him collected.

Lawyers reckon three sorts of records; viz. a judicial record, as attainer, &c.; a ministerial record upon oath, as an office of inquisition found; and a record made by conveyance and consent, as a free, or deed enrolled, and the like.

Record, Affurias by matter of, are such as do not entirely depend on the act or consent of the parties themselves; but the function of a court of record is called in, to substantiate, preserve, and be a perpetual testimony of the transfer of property from one man to another; or of its establishment, when already transferred: of this nature are private acts of parliament, the king's grants, fines, and common recoveries.

Record, Court of. See Record, supra, and Court.

Record, Debt of, is a sum of money, which appears to be due by the evidence of a court of record. Thus, when a specific sum is adjudged to be due from the defendant to the plaintiff, on an action or suit at law, this is a contract of the highest nature, being established by the sentence of a court of judicature. Debts upon recognizances, together with statutes merchant, and statutes staple, &c. if forfeited by non-performance of the condition, are also debts of record; the contract, on which they are founded, being witnessed by the highest kind of evidence, viz. by matter of record.
ors in rendering this branch of knowledge clear and familiar. He is likewise mentioned as remarkably skilled in rhetoric, alchemy, geometry, music, mineralogy, and every part of natural history. He was well acquainted with the Saxon language, and made large collections of historical and other ancient manuscripts. To these various studies he joined that of divinity, and was attached to the principles of the Reformers. But notwithstanding he was justly deemed a prodigy of learning and talents, it does not appear that he met with encouragement at all adequate to his merits; since all that we know further of him is, that he died in the king’s bench prison, where he was confined for debt, in the year 1558.

He was author of several works, some of which were several times reprinted, on the following subjects.

“*The Ground of Arts, teaching the Work and Practice of Arithmetic, both in whole Numbers and Fractions,*” 1542. This was dedicated to king Edward VI. “*The Whetstone of Wit,*” a second part of the former. “*The Pathway to Knowledge, containing the first Principles of Geometry,*” “*The Cattle of Knowledge, containing the Explanation of the Sphere,*” “*The Urinal of Physick,*” 1547, which was reprinted in London in 1582, 1599, and 1665; and in the last mentioned year, the title of “*The Judicial of Urine*” was given to it. This book contains a description of urinary vessels with figures. It is short, but very methodical treatise, full of divisions and subdivisions relative to the different kinds of urines, and the prognostics to be deduced from them. Nevertheless he candidly acknowledges at the beginning, that the judgment to be formed in diagnoses from the urine is not so certain as some have represented; and indeed the perplexity and variety of opinions concerning this subject are sufficiently apparent from his treatise. His other works were, “*Of Anatomy,*” “*Of Auricular Confession,*” “*Of the Eucharist,*” and “*The Image of a true Commonwealth.*” Aikin’s *Biblo. Memoirs of Medicine.*

**REC**

**RECOVERY, Feigned or Common, is a sort of fictio juris, being a certain form or course prescribed by law to be observed for the better affuring of lands and tenements to us; the end and effect of which is, to discontinue and destroy eftates-tail, remainders, and reversions, and to bar the in- tails of them.**

These common recoveries were invented by the ecclesiastics to evade the statutes of mortmain; and afterwards encouraged by the fines of the courts of law in 12 Edw. IV. in order to put an end to all fettered inheritances, and bar not only eftates-tail, but also all remainders and reversions expectant thereon.

A common recovery is so far like a *fine* (which fee), that it is a suit or action, either actual or fictitious; and in it the lands are *recovered* against the tenant of the freehold; which recovery, being a fupposed adjudication of the right, binds all persons, and vells a free and absolute fee-simple in the receiver.

This recovery is either with a *single or double voucher*; and sometimes a treble or farther voucher, as the exigency of the case may require.

As a recovery is in the nature of an *action* at law, not immediately compromised like a fine, but carried through every regular stage of proceeding, its form and method are not easily understood by those who are unacquainted with the course of judicial proceedings. Judge Blackstone has, therefore, stated its nature and progress as clearly and concisely as possible; avoiding, to the utmost of his power, all technical terms and phrases not before interpreted. Of his luminous statement we shall avail ourselves in the sequel of this article.

Let us (says he), in the first place, suppose David Edwards to be tenant of the freehold, and desirous to suffer a common recovery, in order to bar all entailis, remainders, and reversions, and to convey the same in free-simple to Francis Golding. To effect this, Golding is to bring an action against him for the lands; and he accordingly files out a writ, called a *precipe quod reddat,* because those were its initial or most operative words, when the law proceedings were in Latin. In this writ the demandant, Golding, alleges, that the defendant, Edwards, (here called the tenant) has no legal title to the land; but that he came into possession of it after one Hugh Hunt had turned the demandant out of it. The subsequent proceedings are made up into a record or recovery roll, in which the writ and complaint of the demandant are first recited; whereupon the tenant appears, and calls upon one Jacob Morland, who is supposed, at the original purchase, to have warranted the title to the tenant; and thereupon he prays, that the said Jacob Morland may be called in to defend the title, which he so warranted. This is called the voucher, *vocatio,* or calling of Jacob Morland to warranty; and Morland is called the *vouchee.* Upon this, Jacob Morland, the vouchee, appears, is impleaded, and defends the title. Whereupon Golding, the demandant, defires leave of the court to *impart,* or confer with the vouchee in private; which is (as usual) allowed him. And soon afterwards the demandant, Golding, returns to court; but Morland the vouchee disappears, or makes the default. Whereupon judgment is given for the demandant, Golding, now called the recoveror, to recover the lands in question against the tenant, Edwards, who is now the recovery, and Edwards has judgment to recover of Jacob Morland lands of equal value, in recompense for the lands so warranted by him, and now lost by his default; which is agreeable to the doctrine of warranty. This is called the recompense, or recovery in value. But Jacob Morland having no lands of his own, being usually the cryer of the court.
court (who, from being frequently thus vouch'd, is called the common vouchee) it is plain that Edwards has only a nominal reconpence for the lands so recovered against him by Golding; which lands are now absolutely vested in the said recoveror by judgment of law, and feisin thereof is delivered by the sheriff of the county. So that this collusive recovery operates merely in the nature of a conveyance in fee-simple, from Edwards the tenant in tail, to Golding the purchaser.

The recovery, here described, is with a single vouchee only; but sometimes it is with double, triple, or farther vouchee, as the exigency of the case may require. And indeed it is now usual always to have a recovery with double vouchee at the least: by firft conveying an estate of freehold to any indifferent person, against whom the precipe is brought; and then he vouches the tenant in tail, who vouches over the common vouchee. For, if a recovery be had immediately against tenant in tail, it bars only such estate in the premises of which he is then actually feised; whereas if the recovery be had against another person, and the tenant in tail be vouched, it bars every latent right and intrest which he may have in the lands recovered. If Edwards therefore be tenant of the freehold in possession, and John Barker be tenant in tail in remainder, here Edwards doth first vouch Barker, and then Barker vouches Jacob Morland the common vouchee; who is always the last person vouched, and always makes default; whereby the demandant, Golding, recovers the land against the tenant Edwards, and Edwards recovers a reconpence of equal value against Barker the first vouchee; who recovers the like against Morland the common vouchee, against whom such ideal recovery in value is always ultimately awarded.

This supposed reconpence in value is the reason why the inluce in tail is held to be barred by a common recovery. For if the recoveror should obtain a reconpence in lands from the common vouchee (which there is a possibility in contemplation of law, though a very improbable one, of his doing) these lands would supply the place of those so recovered from him by collusion, and would defend to the inluce in tail. This reason will also hold with equal force, as to seque remainders and reversioners; to whom the possibility will remain and revert, as a full reconpence for the reality, which they were otherwise entitled to: but it will not always hold; and therefore, as Pigott says, the judges have been ever aucti, in inventing other reasons to maintain the authority of recoveries. And, in particular, it hath been said, that, though the estate-tail is gone from the recoveror, yet it is not destroyed, but only transferred; and still subsists, and will ever continue to subsist (by construction of law) in the recoveror, his heirs, and assigns: and, as the estate-tail fo continues to subsist for ever, the remainders or reversioners expectant on the determination of such estate-tail can never take place.

To such awkward shifts, such subtle refinements, and such strange reasoning, were our ancestors obliged to have recourse, in order to get the better of that flabby statute de dominis. The design, for which these contrivances were set on foot, was certainly laudable; the univeting the fettors of estates-tail, which were attended with a legion of mischiefs to the commonwealth; but, while we applaud the end, we cannot but admire the means. Our modern courts of justice have indeed adopted a more many way of treating the subject; by considering common recoveries in no other light, than as the formal mode of conveyance, by which tenant in tail is enabled to alien his lands. But, since the ill consequences of lettered inheritances are now generally seen and allowed, and of course the utility and expedience of setting them at liberty are apparent; it hath often been wifhed, that the procs of this conveyance was shortened, and rendered less subject to niceties, by either totally repealing the statute de dominis; which perhaps, by reviving the old doctrine of conditional fees, might give birth to many litigations: or by vesting in every tenant in tail of full age the same absolute fee-simple at once, which now he may obtain whenever he pleases, by the collusive fiction of a common recovery; though this might possibly bear hard upon those in remainder or reversion, by abridging the chances they would otherwise frequently have, as no recovery can be suffered in the intervals between term and term, which sometimes continue for near five months together: or, lastly, by empowering the tenant in tail to bar the estate-tail by a solemn deed, to be made in term and enrolled in some court of record; which is liable to neither of the other objections, and is warranting not only by the usage of our American colonies, and the decisions of our own courts of justice, which allow a tenant in tail (without fine or recovery) to appoint his estate to any charitable use, but also by the precedent of the statute 21 Jac. I. c. 19, which, in case of a bankrupt tenant in tail, empowers his commissioners to sell the estate at any time, by deed indented and enrolled. And if, in a national concern, the emoluments of the officers, concerned in palling recoveries, are thought to be worthy attention, those might be provided for in the fees to be paid upon each enrolment.

The force and effect of common recoveries may appear, from what has been said, to be an absolute bar not only of all estates-tail, but of remainders and reversioners expectant on the determination of such estates. So that a tenant in tail may, by this method of assurance, convey the lands held in tail to the recoveror, his heirs and assigns, absolutely free and discharged of all conditions and limitations in tail, and of all remainders and reversioners. But, by statute 34 and 35 Hen. VIII. c. 20. no recovery had against tenant in tail, of the King's gift, whereof the remainder or reversion is in the King, shall bar such estate-tail, or the remainder or reversion of the Crown. And by the statute 11 Hen. VII. c. 20. no woman, after her husband's death, shall suffer a recovery of lands settled on her by her husband, or settled on her husband and her by any of his ancestors. And by statute 14 Eliz. c. 8. no tenant for life, of any sort, can suffer a recovery, so as to bind them in remainder or reversion. For which reason, if there be tenant for life, with tenant in tail, and other remainders over, and the tenant for life is desirous to suffer a valid recovery; either he, or the tenant to the precipe by him made, must vouch the remainder-man in tail, otherwise the recovery is void: but if he does not vouch such remainder-man, and he appears and vouches the common vouchee, it is then good; for if a man be vouched and appears, and suffers the recovery to be had against the tenant to the precipe, it is as effectual to bar the estate-tail as if he himself were the recoveror. Salk. 571.

In all recoveries it is necessary that the recoveror, or tenant to the precipe, as he is usually called, be actually seised of the freehold, else the recovery is void. (Pigott. 28.) For all actions to recover the feisin of lands, must be brought against the actual tenant of the freehold, else the suit will lose its effect; since the freehold cannot be recovered of him who has it not. And, though these recoveries are in themselves fabulous and fictitious, yet it is necessary that there be altera fabula, properly qualified. But the nicety thought by some modern practitioners to be requisite in conveying the legal freehold, in order to

RECRUE, in Medicine, is a relapse, when a diffeafe that has gone off returns
again.

Recruit-Hoifes, are the horfes brought up for com-
pleting the regiments of hoife or dragons every year.

RECTANGLE, in Geometry, called also oblong, and
long square, a quadrilateral rectangular figure M L I K,
(Plate XII. Geometry, fig. 3.) whole oppofite fides, M L
and I K, as well as M I and L K, are equal.
Or, a rectangle is a parallelogram, whole fides are un-
equal, but its angles right.

To find the area of a rectangle, see PARALLELGRAM.
If from the fame point A, (fig. 4.) be drawn two lines,
one of which, A D, is a tangent to a circle, the other a
fecnat A B; the fquare of the tangent A D will be equal to
the rectangle under the fecnat A B, and that part of it with-
out the circle A C. If two or more fecnats, A a, A B,
&c. be drawn from the fame point A; the rectangles,
under their wholes, and their parts without the circle, will
be equal. If two chords interferf each other, the rectangles
under their segments will be equal. The rectangles under
equal lines are equal. The fum of all the rectangles
contained under a given line, and all the parts of another
any how divided, is equal to the rectangle contained under
the two whole lines. If from any point, within a rectangle,
to the angles of a rectangle, four lines be drawn, the fums
of the fquares of those drawn to the oppofite angles will be
equal. The rectangles contained under the correponding
fides of equiangular triangles, taken alternately, are equal.
The rectangle under the two fides of any triangle is equal to
the rectangle under the perpendicular to its base, and the
diameter of the circumcribing circle. The fquare of a line
bifecling any angle of a triangle, and terminating in the oppo-
fite fide, together with the rectangle under the two seg-
ments of that fide, is equal to the rectangle of the two fides,
including the propcfed angle. The rectangle of the two
diagonals of any quadrilateral infcribed in a circle, is equal
to the fum of the two rectangles contained under the oppo-
fite fides.

Rectangles, Similar. See SIMILAR.

Rectangle, in Arithmetic, is the fame with product or
factor.

RECTANGLED, Right-angled, Triangle, is a tri-
gle, one of whose angles is right, or equal to 90°. See
Triangle.
There can be but one right angle in a plain triangle; therefore a rectangle triangle cannot be equilateral.

RECTANGULAR, in Geometry, is applied to figures and solids which have one or more angles right.

Such are squares, rectangles, and rectangular triangles, among plain figures; cubes, parallelepipeds, &c. among solids.

Squares are also said to be rectangular with respect to their situation: thus, if a cone, cylinder, &c. be perpendicular to the plane of the horizon, it is called a rectangular or right cone, cylinder, &c.

The ancients used the phrase rectangular section of a cone, to denote a parabola; that conic section, before Apollonius, being only considered in a cone, whose section by the axis would be a triangle, right-angled at the vertex. See Conic Sections.

Hence it was that Archimedes entitled his book of the quadrature of the parabola, by the name of "Rectanguli Coni Seclio."

RECTANGULAR Barometer. See Barometer.

Rectangular Windsmills. See Windmills.

RECTIFICATION, compounded of redact, right, direct, and so, I became, the act of rectifying, i.e. of correcting, remedying, or redressing, some defect or error, in respect of either of matter, art, or morality.

Rectification, in Chemistry, is the repeating of a distillation or sublimation several times, and generally with a less degree of heat than at first, in order to render the substance purer, finer, and freer from aqueous and earthy parts.

Rectification is a reiterated separation of a distilled matter, e.g. brandy, spirits, or oils, by distilling them over again, to render them more subtile, and exalt their virtues.

That the rectification of spirits may, in all cases, proceed with the greatest exactness, a due regard to it must be had even from the first fermenting the substance from which they are to be made, and continued through all the stages of distillation, the low wines, proof spirit, and alcohol. The management of the fermented liquor, to this purpose, is principally the letting it stand to subside after the fermentation is over, and the drawing it off clear and thin, not too rich for the still. The still is not to be overfilled with this.

Great care must be taken to prevent its burning, and the faints that run last must be kept separate, not mixed with the rest of the liquor distilled, which is now called the low wines. In the rectifying of these into proof spirit, great caution must be used that the fire be kept regular, not raised by sudden spirits, which always throw up the oil in large quantities, which is to be left behind. In the succeeding rectification of the proof spirit into alcohol, the fame cautious management of the fire is necessary; and, in both this and the last, the fains are not to be suffered to run in among the spirit, but to be faved separate. They may be all mixed together at last, and reduced to a spirit fit for burning in lamps; but the keeping out of the rectified liquor will keep away the coarfeft and most fluctuating part of the oil of the ingredients.

By these easy means, without any additional trouble or charge, we might be furnished with a spirit greatly exceeding what we commonly meet with. And in general, the art and mystery of our fellers of the several sorts of English brandies, seem to consist in this prudent management, and in the adding a little of the olum vini, or oil of wine-lees, to the spirits thus procured pure: this gives the flavour of foreign brandies, and is so extensive in its use, that half an ounce of it is sufficient for a hoghead of pure spirit.

Malt spirit is that which principally requires all this care in the rectification, because its oil is more nauseous and offensive than that of any other spirit; but all others will be greatly the better for being treated in the same manner, and it is indeed necessary that they should for some particular uses.

It is remarkable, that no one method of combinatory rectification, that is, of the rectification performed by means of falt, and other additions, is suited to all the several kinds of spirits: scarcely indeed will any one way serve for any two spirits: but this method, by simple and careful distillation, is equally suited to all. Molasses-spirit, cyder-spirit, wine-spirit, or brandy, run, and arrack, are all improved by it; and all of them are then known to be perfectly rectified, when, in the flate of alcohol, they not only prove, totally inflammable in a little vefel floating upon cold waters, but when poured into the puref spring water they have not the least power of making any change in it; nor leave any marks of oilinefs, or that inacuity which, on the mixture of the lefs pure spirits, floats on the top, and in certain lights gives the rainbow colours. Shaw's Effay on Distillation. See Alcohol and Distillation.

Fixed salts are rectified by calcination, dissolution, or filtration.

Metals are rectified, i.e. refined, by the coppel; and regulxes by repeated fusions, &c.

In a word, all rectifications are founded upon the same principle; and confift in separating substances more volatile from substances less volatile; and the general method of effecting this is to apply only the degree of heat which is necessary to caufe this separation.

RECTIFICATION of vitriolic Acid. See Concentration.

Rectification, in Geometry, is the finding of a right line equal to a proposed curve, or simply finding the length of a curve line; a problem which, even in the prefent advanced state of analysis, is attended in many cases with considerable difficulty; and was, in all, totally beyond the reach of the ancient geometers, who were not able to assign the length of any curve line whatever; though they could, in a few infances, determine the area of a curvilinear space. See Quadrature.

The first rectification of a curve line was effected by Mr. H. Neal, as we are informed by Dr. Wallis, at the conclusion of his Treatise on the Cifloid. This curve was the femicubical parabola, and Neal's rectification of it was publifhed in July or Augulf, 1657; and two years after, viz. in 1659, the fame was done by Van Haureat in Holland. See Schoten's Commentary on Defcartes' Geometry.

It is, however, to the doctrine of fluxions that we owe the complete rectification of curve lines, in finite terms, when they admit of it; and in others by means of infinite series, circular arcs, logarithms, &c.; of which method we fhall give a general view in the prefent article.

Let A M O (Plate XIII. Analysis, fig. 10.) be a curve of any kind, whole ordinates are parallel to one another, and perpendicular to the axis A H; and let the fluxion of the abfide A P be denoted by P p or M R, and R m be taken to repreffent the corresponding fluxion of the ordinate P M, then will the tangent M m be the line which the generating point of the curve would describe, if its motion were to become uniform at M; consequently this line will truly express the fluxion of the space A M. Hence putting A P = x, P M = y, and A M = z, we have z = M m = \( \sqrt{(M R^2 + R m^2)} \) = \( \sqrt{(x^2 + y^2)} \); from which, and the equation of the curve, the value of z may be determined. But if all the ordinates of the proposed curve A R M (fig. 10.) be referred to a centre C; then, putting the tangent R P, intercepted by the perpendicular C P, = t, the arc B N, of a circle described about the centre C, = x, the radius
RÉCTIФICATION.

radius CN (or CB) = a, &c. (see Quadrature of Curves, Cafe 2,) we shall have \( \dot{z} : j : y \) (C.R. : R.P.); and consequently, \( \dot{z} = \frac{y'j}{t} \); whence the value of \( z \) will be found, if the relation of \( y \) and \( j \) is given.

I. To find the length of the semi-cubical parabola, of which the equation is \( ax^3 = y^2 \); or \( x = \frac{y^2}{a^3} \).

Here \( \dot{x} = \frac{3y^2}{2a^3} \) or \( \dot{x} = \frac{9y^2}{4a} \); substituting, therefore, this value of \( \dot{x} \) in the general expression
\[ \ddot{z} = \left( \frac{9y^2}{4a} + y^4 \right)^{\frac{1}{2}} \]
the fluent of which is
\[ z = \frac{1}{27a^3} \times (9y + 4a) \frac{1}{3} + C, \] correction.

Now when the arc = 0, then \( y = 0 \); therefore
\[ 4 \frac{a^3}{27a^3} + C = 0, \] or \( C = \frac{27}{4} \).

whence the complete fluent is
\[ z = \frac{(9y + 4a)^{\frac{1}{3}} - 4a}{27} \]
which is the length of the curve, answering to any length of the ordinate \( y \).

II. To rectify the common parabola; or to find the length of any parabolic arc AM (fig. 11.) Let the parameter = a, the abscissa = AP = x, &c. as above. From the well known property of this curve, \( a \times y^2 \); and \( a \times x = 2y^2 \); consequently \( \dot{x} = \frac{2y}{a} \), and \( \dot{x} = \frac{4y^2}{a} \), which sub-stituted for \( \dot{x} \) in the general expression for the length of the curve, makes \( \dot{z} = \left( \frac{4y^2}{a} + y^2 \right)^{\frac{1}{2}} = \frac{y}{a} \times (a^2 + 4y^2)^{\frac{1}{2}} \)
which, thrown into an infinite series, becomes
\[ z = \frac{y}{a} \times \left( a^2 + 4y^2 \right)^{\frac{1}{2}} - \frac{2y^2}{a^2} + \frac{4y^3}{a^3}, \] &c.

The fluent of this series is \( z = y + \frac{2y^3}{3a^2} - \frac{2y^2}{5a^2} + \frac{4y^3}{7a^2} \), &c.

Yet, &c. = the length of the curve AM required.

Otherwise the above \( \dot{z} = \frac{y}{a} \times (a^2 + 4y^2)^{\frac{1}{2}} \) is \( \frac{y}{a} \times \left( \frac{a^2 + 4y^2}{a^2 + 4y^2} \right)^{\frac{1}{2}} = \frac{a^2y^2 + 4y^4}{a \times (a^2y^2 + 4y^4)}^{\frac{1}{2}} = \frac{1}{2} \left( \frac{1}{a} \times \left( a^3y^2 + 4y^4 \right) - \frac{1}{2} \right) \times \left( \frac{1}{2} a \times y \right)^{\frac{1}{2}} + \frac{1}{2} \times \frac{y}{a} \times \left( \frac{1}{2} \left( \frac{1}{a} \times \left( a^3y^2 + 4y^4 \right) \right)^{\frac{1}{2}} + \frac{1}{2} \times \frac{y}{a} \times \left( \frac{1}{2} \left( \frac{1}{a} \times \left( a^3y^2 + 4y^4 \right) \right)^{\frac{1}{2}} \right) \right)^{\frac{1}{2}} \). But the fluent of the first of these two terms is \( \frac{1}{2} \times \left( a^3y^2 + 4y^4 \right)^{\frac{1}{2}} = \frac{y}{a} \times \left( \frac{1}{2} a^2 + y^2 \right)^{\frac{1}{2}} \); and the fluent of the last of the two terms is \( \frac{1}{2} a \times \sqrt{y^4 + \left( \frac{1}{2} a^2 + y^2 \right)^2} \); therefore \( z = \frac{y}{a} \times \left( \frac{1}{2} a^2 + y^2 \right)^{\frac{1}{2}} + \frac{1}{2} a \times \sqrt{y^4 + \left( \frac{1}{2} a^2 + y^2 \right)^2} \). But when \( z \) and \( y \) vanish, or become equal, as they do at the vertex, this fluent becomes \( \frac{1}{2} a \times \sqrt{y^4 + \left( \frac{1}{2} a^2 + y^2 \right)^2} \); and, therefore, the said fluent being corrected, gives the true value of \( z \), or the length of the curve \( AM = \frac{y}{a} \times \left( \frac{1}{2} a^2 + y^2 \right)^{\frac{1}{2}} + \frac{1}{2} a \times \sqrt{y^4 + \left( \frac{1}{2} a^2 + y^2 \right)^2} \).

Hence, if \( AC \) and \( DC \) (fig. 12.) be the conjugate semi-axes of an equilateral hyperbola; and \( AC = a, MP = 2y, QM = x \) then will \( AP = x - a \); and \( x^2 - a^2 = 4y^2 \); therefore \( \dot{x} = 4y^2 + a^2 \); consequently \( x = \frac{1}{2} \left( \frac{1}{a} \times \left( a^3y^2 + 4y^4 \right) \right)^{\frac{1}{2}} \). If then \( q \) be supposed infinitely near \( QM \), we shall have \( QQ = j, \) and therefore the element of the area \( CQMA = j \times \sqrt{a^2 + 4y^2} \). Whence it appears, that the rectification of the parabola depends on the quadrature of the hyperbolic space \( CQMA \).

III. To determine the length of an arc of the common hyper- bola. Let the semitransverse axis be represented by \( b \), and the semiconjugate by \( c \), and we shall have \( \frac{b^2y^3}{c^3} = \frac{2b}{x} + x^2 \); from the nature of the curve (see Hyperbola); and therefore \( x = \frac{b}{c} \sqrt{x^2 + y^2} - b \); hence \( \dot{x} = \frac{b}{c} \sqrt{x^2 + y^2} \) and \( \dot{z} = \sqrt{y^2 + x^2} = \sqrt{y^2 + y^2} \) \( \left( \frac{2b}{c} \sqrt{x^2 + y^2} \right)^{\frac{1}{2}} = \frac{2b}{c} \sqrt{x^2 + y^2} \) \( \frac{1}{2} \times \frac{1}{x}$, which, by converting \( \frac{b}{c} \sqrt{x^2 + y^2} \) into an infinite series, becomes \( \dot{z} = (1 + \frac{b}{c} \frac{y}{x} - \frac{b^2}{c^2} \frac{y^2}{x^2} - \frac{b^3}{c^3} \frac{y^3}{x^3}, \text{ &c.} \). But still we have the square root to extract; in order to which, let it be assumed \( 1 + A y^2 + B y^2 + C y^2 + D y^2, \) &c. Then, by squaring, and transposing, there arises
\[ 1 + 2 A y^2 + 2 B y^2 + 2 C y^2 + 2 D y^2, \] &c.
\[ + A x^2 + 2 B x y + 2 A C y^2, \] &c.
\[ + B y^2, \] &c.
\[ - \frac{b^3}{c^3} x^3 \] &c.
\[ = 1 - \frac{b^3}{c^3} x^3 \] &c.

Hence \( A = \frac{b^3}{2c^3} ; \) \( B = - \frac{b^3}{2c^3} - \frac{1}{2} A = - \frac{b^3}{2c^3} - \frac{b^3}{2c^3} \); C
\[ = \frac{b^3}{2c^3} - \frac{b^3}{2c^3} - \frac{b^3}{2c^3} + \frac{b^3}{2c^3} - \frac{b^3}{2c^3}, \] &c.

Therefore \( \dot{z} = \sqrt{1 + \frac{b^3}{c^3} \frac{y}{x}, \text{ &c.} \} = \sqrt{(1 + A y^2 + B y^2, \text{ &c.)}} \]
\[ = j \times (1 + A y^2 + B y^2, \text{ &c.)} \]
\[ = \frac{b^3}{2c^3} x \times y^2 - \left( \frac{b^3}{2c^3} + \frac{b^3}{8c} \right) x y^2 + \left( \frac{b^3}{2c^3} + \frac{b^3}{8c} \right) x \]
RECTIFICATION.

\[
\frac{b^2}{4c^2} + \frac{b^2}{16c^4} \times y^5, \text{ &c. And consequently } z = y + \frac{b^2}{6c^2} y^3 \left( \frac{b^2}{c^2} + \frac{b^2}{4c^4} \right) \times \frac{y^5}{10c^4} + x^3 \frac{b^2}{2c^2} + \frac{b^5}{8c^6} \times y^7.
\]

By the very same way of proceeding, the arc of an ellipse may be found, the equations of the two curves differing in nothing but their signs.

IV. To rectify the spiral of Archimedes. The value of \( t \) (A. T, fig. 13.) being denoted by \( \frac{b y}{\sqrt{(b^2 + y^2)}} \) (see Tangent of the Spiral, &c.) we have \( \frac{y}{t} \left( \frac{b^2 + y^2}{b} \right) \), which fluxion being the same as that expressing the arc of the common parabola (Prob. III.), by inverting the expression \( \frac{y}{t} \left( \frac{b^2 + y^2}{b} \right) \), \( b \) for \( \frac{1}{2} a \), its fluent will, therefore, be truly represented by the measure of the said arc, or by \( \frac{1}{2} y \sqrt{(b^2 + y^2)} + \frac{1}{2} b \times \text{hyp. log.} y + \sqrt{(b^2 + y^2)} \), the value there found, by making the proposed substitution.

V. To rectify the involute of a circle, whose nature is such, that the part \( P R \) (fig. 14.) of the tangent intercepted by the point of contact and the perpendicular \( CP \), is everywhere equal to the radius \( CO \) of the generating circle.

In this case \( \frac{y}{t} \left( \frac{b^2 + y^2}{b} \right) \), which corrected by making \( y = a = AC \), becomes \( \frac{y^2}{2a} \), which, being expressed by \( y = a = AC \), becomes \( \frac{y^2}{2a} \left( \frac{CP}{2CA} \right) \), the true measure of the required arc \( A R \).

VI. To find the length of a circular arc.—This may be expressed either in terms of the fine, co-tangent, rectified, or any other trigonometrical line, as follows.

Let the rectified fin = \( x \), the fine = \( y \), radius = \( r \), and arc = \( z \), then, by the property of the circle, \( y^2 = 2rx - x^3 \) or, putting tangent = \( t \),

\[ y^2 = \frac{r^2 t^2}{r^2 + t^2} \]

and secant = \( s \) gives

\[ y^2 = \frac{s^2 - r^2}{s^2} \]

as are readily deduced from the known properties of the circle.

Now, by means of these values of \( y^2 \), or of \( 2rx - x^3 \), and the general equation \( \frac{y^2}{t} = \sqrt{(x^2 + j)} \), we readily draw the following values of \( \frac{y^2}{t} \), viz.

\[
\frac{y^2}{t} = \begin{cases} \sqrt{(2rx - x^3)} & \text{if } j = 0 \\ \sqrt{(r^2 - y^2)} & \text{if } j = 1 \\ \frac{r^2}{r^2 + t^2} & \text{if } j = 2 \\ \frac{r^2}{t} & \text{if } j = 3 \\
\end{cases}
\]

the fluents of which can only be found in series, which are as follows; making radius \( r = 1 \), viz.

Having
RECTIFICATION.

Having thus laid down his plan of operation, by a few
trials he fell upon a number well suited to his purpose, viz.
knowing the tangent of \(\frac{1}{4}\) of 45°, or 11° 15', to be very
nearly \(\frac{1}{5}\), radius being 1, he assumed for his first arc that
whose tangent is \(\frac{1}{5}\); then since \(\tan 2a = \frac{2\tan a}{1 - \tan^2 a}\),
he had \(\frac{5}{12}\) for the tangent of his double arc, and \(\frac{5}{119}\)
for the double of this, or of four times the first, which being
a little greater than 45°, was well adapted to his views; for
by a known trigonometrical property, \(\tan (a + 45°) =
\frac{\tan a - 1}{\tan a + 1}\); that is, the tangent of the small arc, which is
equal to the excess of his multiple above 45°, was
\[\frac{1}{239}\] He had, therefore, two arcs to compute, the one
having for its tangent \(\frac{1}{5}\), and the other \(\frac{1}{239}\); and then four
times the first of these arcs minus the latter, would evidently give the exact arc of 45°, and both these numbers
being such as to converge very well in the general series, the
difficulty attending the usual approximation was avoided.
Other approximations, however, have since been discovered,
which, if not more rapid, their investigation is, at least,
more simple, of which, perhaps, that of Euler's is the most
deferring of notice. This celebrated geometrical observs, that
every arc whose tangent is commensurable with the radius,
as, for instance, 45°, may be divided into two arcs, of
which the tangents, though much smaller, are still commensurable with the radius; for since
\[\tan (a + b) = \frac{\tan a + \tan b}{1 - \tan a \tan b}\]
we have also
\[\tan a = \frac{\tan (a + b) - \tan b}{\tan (a + b) \cdot \tan b + 1}\]
where it is obvious that if \(\tan (a + b)\) and \(b\) be rational,
\(\tan a\) will also be rational; thus, if \(\tan (a + b) = \tan 45°\)
= 1, and \(\tan b = \frac{1}{2}\), we have \(\tan a = \frac{1}{3}\), and we shall
evidently have a similar result, whatever rational fraction we
assume for \(\tan b\).

We shall find, therefore, by the series which gives the arc
in terms of the tangent, each of these arcs, the sum of which
will evidently be the measure of the whole arc sought; whether
the arcs themselves, which belong to these tangents, be rational or irrational, with respect to the whole arc of
which they form the parts. These tangents, subtilted in
the general series above, give arc to tan
\[\left(\frac{1}{2}\right) = \frac{1}{2} - \frac{1}{3} \cdot \frac{1}{2} + \frac{1}{5} \cdot \frac{1}{2} - \frac{1}{7} \cdot \frac{1}{2} + \frac{1}{9} \cdot \frac{1}{2} - \&c.\]
and arc to tan \(\left(\frac{1}{3}\right) =
\[\frac{1}{3} - \frac{1}{3} \cdot \frac{1}{3} + \frac{1}{5} \cdot \frac{1}{3} - \frac{1}{7} \cdot \frac{1}{3} + \frac{1}{9} \cdot \frac{1}{3} - \&c.\]

In both which series, the terms diminish much more rap-
didly than in the original series, and may therefore be com-
puted with tolerable ease.

But it is evident that we may proceed farther in this ap-
proximation, by dividing each of these into other two arcs,
by which means the convergency will obviously be much
more rapid; and though, generally speaking, for every sub-
division we double the number of our series, yet the degree
of convergency is so much the greater as amply to com-
pensate for the additional number of series. Besides, we may
always subdivide our greater arc, so that one of its subdivi-
sions shall be the same as the smaller arc, in which case we do not
increase the number of series. Thus; arc to tan \(\frac{1}{2}\) = arc
to tan \(\frac{1}{3} + \text{arc to tan} \frac{1}{7}\); therefore arc to tan \(\frac{1}{7} = 2\)
arc to tan \(\frac{1}{3} + \text{arc to tan} \frac{1}{7} = 1\).
Again; arc to tan \(\frac{1}{3} = \text{arc to tan} \frac{1}{11} + \text{arc to tan} \frac{1}{7} = 2\)
Therefore arc to tan \(1 = 3 \text{arc to tan} \frac{1}{7} + 2 \text{arc to tan} \frac{2}{11}\), and so on to
any extent required, which might in course be pursued so
far as to render the operation as simple and as little laborious
as can be expected in such kind of computations. Even
with these already mentioned, the circumference of the circle
might undoubtedly be computed to 200 places of decimals,
with less labour than it cost Vieta to carry them to 10 places,
or Romanus to 15.

The reader will observe, that this approximation differs
from Machin's in nothing except the simplicity and gener-
ality of the investigation; for if we make the successive
subdivision of the greater arc, so as always to include in it
the smaller one, we shall find in our results the identical
formula of Machin.

Let us repeat our former expression
\[\tan a = \frac{\tan (a + b) - \tan b}{1 - \tan a \cdot \tan b}\]
Let tan \(a + b = \frac{R}{T}\), tan. \(a = \frac{R}{T}, \) tan. \(b = \frac{r}{t}\) and

we shall have generally \(\frac{R'}{T'} = \frac{R \cdot R - T \cdot T'}{T \cdot T'}\)

Let now tan. \((a + b) = 1,\) answering to arc 45°, so that
\(R = 1,\) and \(T = 1;\) assume also \(r = 1,\) then, by cont-
stantly subdividing; in the general expression, the values
found for \(R', R'', R''', \&c.\) and \(T', T'', T''', \&c.\) for \(R\) and \(T\) respectively, we shall have
\(R' = \frac{t - 1}{t + 1}\)
\(T' = \frac{t + 1}{t - 1}\)
\(R'' = \frac{t^2 - 2t - 1}{t^2 + 2t - 1}\)
\(T'' = \frac{t^2 + 2t - 1}{t^2 - 2t - 1}\)
\(R''' = \frac{t^3 - 3t^2 - 3t + 1}{t^3 + 3t^2 - 3t - 1}\)
\(T''' = \frac{t^3 + 3t^2 - 3t - 1}{t^3 - 3t^2 - 3t + 1}\)
\(R'''' = \frac{t^4 - 4t^3 - 6t^2 + 4t + 1}{t^4 + 4t^3 - 6t^2 - 4t + 1}\)
\(T'''' = \frac{t^4 + 4t^3 - 6t^2 + 4t + 1}{t^4 - 4t^3 - 6t^2 + 4t - 1}\)

and \(R = \frac{t^4 - 5t^3 - 10t^2 + 10t + 5t - 1}{t^4 + 5t^3 - 10t^2 - 10t + 5t + 1}\)
\[ \frac{R^{(n)}}{T^{(n)}} = \frac{t^n - n t^{n-1} + n(n-1) \frac{1}{2} t^{n-2} + \&c.}{t^n + n t^{n-1} - n(n-1) \frac{1}{2} t^{n-2} + \&c.} \]

So that, generally, arc to tan. \( i = \frac{n}{t} \) are to tan. \( \frac{1}{i} + \) are given its fastened each this.

If we take \( n = 1 \), and \( t = 3 \), we have arc tan. \( \frac{1}{3} + \) arc tan. \( \frac{t}{2} \).

If \( n = 2 \), and \( t = 3 \), we have arc tan. \( \frac{2}{3} \) + arc tan. \( \frac{1}{7} \).

If \( n = 4 \), and \( t = 5 \), we have arc tan. \( \frac{4}{5} \) - arc tan. \( \frac{1}{5} \)

are tan. \( \frac{239}{7} \); which is the formula of Machin; and by giving other values to \( n \) and \( t \), a variety of other formulæ might be found, though it would, probably, be difficult to find one more convergent than the last. The reader will find more on this subject in vol. i. of Dr. Hutton's Tracts.

We shall conclude this article by giving the circumference of the circle to 155 places, as given by Zach, from a manuscript which he has in the Ratcliff library at Oxford, distinguishing the periods of the several approximations of different authors mentioned in the preceding part of this article, and the article Quadrature.

The diameter of a circle being \( i \), the circumference will be

\[ \begin{array}{cccc}
a & b & c & d \\
3.14159 & 3.2535 & 3.8973 & 3.5846 \\
2.6433 & 3.5287 & 5.0288 & 4.1971 \\
6.9399 & 3.7510 & 5.3209 & 7.4944 \\
5.9230 & 7.8164 & 6.0286 & 2.0899 \\
8.6280 & 3.4825 & 3.4211 & 7.679 \\
8.2148 & 0.8651 & 3.2823 & 0.6647 \\
0.9384 & 4.095 & 5.0582 & 2.3172 \\
5.3594 & 0.8128 & 4.8202 & \\
\end{array} \]

* This figure is a \( 7 \) in Lagyn's approximation, but Vega, in the revision of the computation, afferts that it ought to be an \( 8 \), as we have given it.

RECTIFIED Spirits, &c. are such as have undergone the operation of rectification, or have been distilled over and over, to separate from them any heterogeneous matter, which might have arisen with them in the former distillations.

Hence we say, spirit of wine twice rectified, thrice rectified, &c.

It is the rectification that makes the difference between brandy and rectified spirits of wine. See Spirits.

RECTIFIER, in Navigation, is an instrument used to determine the variation of the compass, in order to rectify the ship's course, &c.

It consists of two circles, either laid upon, or let into one another, and so fastened together in their centres, that they represent two compasses, the one fixed, the other moveable; each is divided into thirty-two points of the compasses, and three hundred and sixty degrees, and numbered both ways, from the north and the south, ending at the east and west in ninety degrees.

The fixed compass represents the horizon, in which the north, and all the other points, are liable to variation.

In the centre of the moveable compass is fastened a silk thread, long enough to reach the outside of the fixed compass; but if the instrument be made of wood, an index is used instead of the thread.

RECTIFIER, in the Distillery, the person whose employment is to take the coarse malt-spirit of the malt-stiller, and re-distil it to a finer and better liquor. The art of the rectifier might be entirely let aside, if the malt-stiller could make his spirit perfect at a second operation; which seems very practicable, if the malt-stillers be induced to forake their old practice. The great things to be recommeded for the improvement of their art, would be, first, the brewing in perfection; and secondly, the keeping of their wash after the manner of flale beer, till it has entirely loft its malt flavour, and acquired a pungent acid vinosity; and then, thirdly, leaving out the lees, to distil with a well-regulated fire. It is scarcely to be thought how pure a spirit is to be obtained from malt this way; but the great art would be, the finding of a method to make malt liquors artificially flale, bright, and flavoursome, though otherwise vinous.

Shaw's Lectures, p. 223.

RECTIFYING of Curves. See Rectification.

RECTIFYING of the Globe or Spheres, is a previous adjusting of the globe or sphere, to prepare it for the solution of problems. For the method of doing it, see Use of the Celestial Globe.

RECTILINEAR, RIGHT-LINED, in Geometry, is applied to figures whose perimeter consists of right lines.

RECTILINEAR Angles, Maps, and Superficies. See the substantives.

RECTITUDE, RECTITUDE, Rectum, in matters of philosophy, refers either to the act of judging, or of willing; and therefore, whatever comes under the denomination of rectitude is either what is true, or what is good; the being the objects about which the mind exercises its two faculties of judging and willing.

Rectitude of the mind, considered as it judges, i.e. rectitude of the faculty of judgment, consists in its agreement and conformity to the nature and reason of things, and in its determining and deciding about them according to what their constitutions, properties, uses, &c. really are.

Rectitude of the mind, considered as it wills, called also moral rectitude, or uprightness, consists in the choice and pursuing of those things which the mind, upon due enquiry and attention, clearly perceives to be good; and avoiding those that are evil.

RECTITUDINES, in Laws, rights, or legal dues, belonging either to God, or man. See Right.

RECTO, a writ usually called a writ of right; of so high a nature, that whereas other writs in real actions are only to recover the possession of the lands, &c. in question, lost by the plaintiff, or his ancestor; this aims to recover both the feinit thus lost, and the property of the thing; so that both rights are here blended together; that of property, and that of possession.

If a man lose his cause upon this writ, he is without all remedy.

There are two kinds of this writ: breve magnum de rebus, or
or breve de recto patris, a writ of right patent; and recto clausum, a writ of right clore.

The first is so called, because fe closed. It lies only for him that hath fee-simiple in the lands fuited for, against the tenant of the freehold at least.

Indeed, the writ of right patent is extended, in practice, beyond its original invention; for a writ of right of dower, which lies for the tenant in dower, is patent; and so in several other cases. Fitzherbert.

The writ of right clore, called also breve parsum de recto, is directed to the lord of ancient demesne, or the bailiff of the king's manors; and lies for those who hold lands and tenements by charter, in fee-simiple, or in fee-tail, or for term of life, or in dower, if they be ejected out of such lands, or diffleed. In such case a man, or his heirs, may sue out the writ of right clore, directed to the lord of ancient demesne, commanding him to do him right in his court. This is called a writ fictandum confiduum maneri. See Possession, Property, Title, and Writ.

Recto de advocacione ecclesiæ, a writ of right, lying where a man has right of advowson in fee to him, and his heirs; and, the incumbent dying, a stranger presents his clerk to the church; and he, not having brought his action of querre impedit, nor darrein prefentum, within six months, has suffered the stranger to usurp upon him. See Diflurbance of Patronage, Quare impedit, and Assisa darrein prefentum.

Recto de cyphidia terre & bareidis, a writ which lies for him whose tenant dying in his nanage, a stranger enters, and takes the body of the heir.

This writ as to lands helden in capite, or by knight's service, is become ufeles by the Stat. 12 Car. II. but not where there is a guardian in focage, or appointed by the latt will of the ancestor. See Guardian.

Recto de dot, a writ of right of dower, which lies for a woman that has received part of her dower, and proceeds to demand the remnant in the same town against the heir, or his guardian. This extends either to part or the whole, and is a more general remedy than that mentioned in the next article.

Recto de dot unde nihil habet, is a writ of right which lies in a cafe where the husband, having divers lands and tenements, has asfured no dower to his wife; and she is thereby driven to sue for her thirds against the heir, or his guardian. See Dower, and Writ of Entry.

Recto quando or quia dominus remittit, a writ of right, which lies in a case where lands or tenements in the suitcase of any lord, are in demand by a writ of right.

If the lord hold no court, or, at the prayer of the demandant or tenant, fend his writ to the king's court, to put the caufe thither for that time; this writ ilues for the other party, and has its name from the words comprised, which is the true occasion of it.

Recto de rationabili parte, a writ that lies between pri- vies of blood, as brothers in gavel-kind, or fitters, or other coparencers, as nephews and nieces, and for land in fee-simiple.

If a man leave his land for life, and afterwards die, leaving his two daughters, and, after, the tenant for life likewife dies; the one fitter entering in all the land, and for defouring the other, the fitter so deforced shall have this writ to recover her part.

Recto fur disclaimer, a writ which lies where the lord, in the court of common pleas, does now upon his wont, and the tenant disclaims to hold of him; upon which disclaimer the lord shall have this writ. This takes place when the tenant upon a writ of affiute for rent, or on a re-plevin, difowns or disclaims his tenure; whereby the lord loses his verdict; in which case the lord may sue this writ, grounded on this denial of tenure, and shall, upon proof of the tenure, recover back the land itself to holden, as a punishment to the tenant for such his false disclaimer. This piece of retaliating justice, whereby the tenant who endeavours to defraud his lord is himself deprived of the estate, as it evidently proceeds upon foedal principles, so it is expressly to be met with in the foedal constitutions: "vallalus, qui abnegavit feudum eujus conditionem, expoliosa bitur."

RECTOR. See Folio.

RECTOR of a parish, the parson, or he who has the charge or cure of a parish church. See PARSON.

If the predial tythes of the parish be impropriated, or appropriated, i.e. either in lay hands, or in those of some ecclesiastical community, then, instead of rector, the parson is called vicar, (which fee). In England are reckoned 3485 rectories.

The same rector denotes him governor or ruler, quia tantum jus in ecclesia parochiali habet, quantum prælatus in ecclesia collegiata.

RECTOR also denotes the chief elective officer in several foreign universities, particularly in that of Paris.

RECTOR is also used in several convents for the superior, or officer who governs the house.

The Jesuits used it for the superiors in such of their houses as were either seminaries, or colleges.

RECTORY, or RECTORATE, rectaria, a parish church, parsonage, or spiritual living, with all its rights, glebes, and tythes.

RECTRICES, in Ornithology, denote the strong feathers of the tails of birds.

RECTUM intestinum, in Anatomy; or in English, simply the rectum; is the last portion of the large intestine, and of the whole alimentary canal. It begins at the left sacro-iliac symphysis, below the sigmoid flexures of the colon, and ends at the anus. See Intestine.

RECTUM, Abbeys in the Neighbourhood of. See Fis- Tula in Avo.

RECTUM. Concretions and extraneous Substances lodged in the coatings formed in the larger intesines, and especially in the rectum, by the accumulation and protracted lodgment of the feces, may become the cause of oblitinate constipation, which can only be removed by their extraction. Sometimes these matters of induratated matter include no extraneous substance; in other instances, their nucleus is a biliary calculux; in a vast number of cases, they are merely composed of the feces in a dry hardened state. It is remarked that women, and persons of advanced age, are most subject to the constipation arising from the obstruc- tion thus occasioned in the large intesines. Children and adults in the vigour of life are not, however, entirely exempt from the disorder, though they seldom have it, except when the formation of such concretions in the bowels has been brought on by swallowing a large quantity of hard indige- nible bodies, like cherry and plum-stones. Lastly, exceedingly hardened matters of fecal matter have been noticed in patients who have for a long while been confined to bed in the recumbent posture by severe diseafes.

Whatever may be the cause of the disorder, whether the defect itself consists in a mere accumulation of induratated feces, with which the rectum is diffled, and behind which the excrement is detained; or whether the concretion is not complete, the concretion allowing the liquid part of the feces to pass out between it and the intesine of the intestine; the existence of the hardened masses may be known
by the constipation which it produces; by the sense of weight which the patient feels about the fundament; and also by the possibility of actually touching the indurated obstructing body, when a finger is introduced up the rectum.

Oily emollient clysters, and carminative draughts, will serve for expelling such concretions as are not of too firm a consistence; but the extraction of them is absolutely necessary when they are particularly hard. The operation is to be done with a spoon, or suitable forceps, properly oiled; and, after the concretion has been removed, an emollient clyster is to be administered, in order to allay any irritation which may have been caused by the introduction of the requisite instruments. When the sphincter ani contracts so forcibly, that the operation is attended with extreme pain and difficulty, we are advised by surgical writers to make a dilatation of the anus, by piercing an incision at its posterior angle. A wound made in this direction cannot do injury to any part of consequence, whilst there would be a risk of wounding the urethra in the male, or the vagina in the female subject, if the cut were made at the anterior angle. An incision, carried laterally, would be apt to injure the pudic vessels. A division of the fibres of the sphincter ani does not produce any material permanent weakness of its action, and a paralysis of this muscle, according to Richard, can never proceed from such a cause.

Nefrologie Chirurgicale, tom. iii. p. 414, edit. 2.

The hard concretions which lodge in the rectum cannot be reached with the finger when they are situated high, and, in this circumstance, the surgeon must use a probe, or found, in order to allure himself positively of their presence, their moveableness, and their size.

With regard to foreign bodies lodged in this intestine, some have been swallowed, and have passed through the whole extent of the alimentary canal; while others have been pushed up the anus to a greater or lesser height. The extraction of these last is generally attended with a great deal of difficulty, and even demands on the part of the operator more than ordinary sagacity, in consequence of the various shapes, the hardness, and the fragility of these different bodies. Glasses, phials, instrument cases, shuttles, &c. have been introduced into the rectum by maniacs. One person of this description put into his rectum a flaming stone, which did not admit either of being extricated, or broken, owing to its hardness, and slippery surface, and which in the end caused the patient to die in the greatest agony, with swelling and gangrenous mischief in the abdomen. Marchetti has recorded an instance, in which a pig's tail, hardened by cold, was forcibly thrust up the rectum of a girl of the town. This extraneous body could not be withdrawn, as the short bristles, which all inclined outward, immediately came into contact with and pierced the inner part of the bowel. It remained in the part six days, and occasioned a train of alarming symptoms, such as fever, vomiting, swelling of the abdomen, and obstinate confinement. Marchetti fell on a ligature to the end of the foreign body, which protruded at the anus, and then pulled the ligature through a long piece of reed, which he introduced up the rectum, in order that the foreign body might be drawn through this tube without the intestine being lacerated. The experiment was completely successful. Obf. Med. Chir. p. 126.

In another example a piece of wood, three inches long, and two in width, was introduced into the rectum. Colic, tension of the abdomen, fever, confinement, and difficulty of making water, came on, and lasted six days. The impossibility of removing the extraneous substance with a pair of forceps, led to the idea of using a borer, which, having been pushed up the rectum under the guidance of the finger, was inserted deeply enough into the piece of wood to draw it out. The extraction, however, could not be effected without a great deal of pain. See Mélange de Chirurgie, par M. Saucerotte, p. 484. Mémoires de l'Académie de Chirurgie, tom. v. p. 607. Lafius, Pathologie Chirurgicale, tom. ii. p. 369, edit. 2.

RECTUM. Congenital and Syphilitic Contractions of its inferior Portion. A contraction of the lower end of the rectum is sometimes an original malformation; but more frequently it arises from what has been considered by various surgical authors to be a venereal thickening of the parietes of this intestine. If this be really a syphilitic disorder, a circumstance which is to be doubted, it is certainly as grievous as any of the more common effects of the venereal disease. Excrecences grow from the mucous membrane at the rectum, and discharge a purulent matter, which is continually oozing from the anus. When a finger is passed within this aperture, the irregularities occasioned by the tumour may be plainly felt. Such writers as believe in the syphilitic nature of this complaint inform us, that the truth of the matter may be ascertained by the antececedent and co-existent symptoms of the venereal disease. They admit, however, that the disorder almost always lasts after the cure of every other mark of syphilis, and they caution us not to persevere rashly in administering mercury any longer for a disease which cannot be further benefited by it. These circumstances are quite sufficient to prove that there is not much reason for the doctrine, that this fort of contraction of the lower end of the rectum is venereal.

Such writers as consider the complaint to be connected with syphilis, of course recommend the exhibition of mercury, and they further advise the frequent injection into the rectum of a weak solution of the oxide of the same mineral. Tottoes, fmeared with mercurial ointment, are also recommended to be passed into the bowel. The latter applications are stated to have the advantage; 1st, of opposing, by mechanical pressure, the further increaase of the excrecences; 2dly, of dilating the contracted part; and, 3dly, of acting on the disease by their medicinal quality.

For our own part, we much doubt the reality of the venereal nature of the foregoing complaint. The language of the advocates for such a doctrine must rafe suspicions, that they are influenced in their judgment more by prejudice than reason. "The venereal affection of the coats of the rectum (says one of these writers) almost always lasts after the total extinction of the syphilitic virus. Then, we ought to be content with the employment of diluting mechanical means, without perfolishing in the use of medicines, which would serve only to ruin the patient's constitution. An elixir gum canthar. is to be preferred, and it should be of a conical shape, in order that it may be gradually introduced further and further, in proportion as the dilatation of the bowel is effected." Richerand, Néurologie Chirurg. tom. iii. p. 418, edit. 2.

In cases of congenital contraction of the rectum, the only plan which can be adopted, is that of making an incision through the posterior part of the intestine.

RECTUM. Polypli of. Sometimes, though not often, polypi grow from the mucous membrane of the rectum, and by their size obtrude the passage of the feces. Their existence is at first manifested by an uneasy sense of heaviness, and afterwards they are protruded outwardly in the efforts which the patient makes at stool. The anus contracting after the expulsion, their roots become strangulated, so that they cannot return, and excessive agony is produced.
In this circumstance, the surgeon should take the opportunity of removing them with a knife, after having tied their root, or even without this precaution. The lining of the rectum, freed from the weight of the tumour, immediately retracted, and if the polypus should have received a supply of blood from a large vessel, hemorrhage may ensue. Such accident may be remedied by completely dilating the wound part of the rectum with a large piece of sponge, or with a compref of lint; but if it is easier to prevent the hemorrhage altogether, than to stop it after it has occurred, we would advise surgeons, whenever the excrecence is of any size, always to tie its root before removing the rest of it with a cutting instrument.

**RECTUM, Prolapsus of.** See Prolapsus Ani.

**RECTUM, Stenirho-contracted.** Stricture of the rectum is not uncommon at an advanced period of life. Sometimes it extends over a considerable length of the gut, but generally it is more circumferibed. The coats of the bowel become much thicker and harder than in the natural state. The muscular coat is subdivided by membranous septa, and the internal coat is sometimes formed into hard irregular folds. The surface of the internal membrane is occasionally ulcerated, so as to form a cancerous diseaee. Every vellitude of the natural structure is occasionally lost, and the gut is changed into a gritty substance. The cavity of the bowel is always rendered narrow at the stricture part, and is sometimes much obliterated. When the passage through the gut is much obstructed, the bowel is always a good deal enlarged just above the foppage, or strictu re, from the accumulation of the feces there. As the disease advances, adhesions form between the rectum and adjacent parts, and ulcerations produce communications between them.

The disease is usually not much noticed till somewhat advanced, not being at first very painful. The patient only thinks that he is collive, and that he voids his foids with a little difficulty. In time, a good deal of pain is felt in the part affected, especially at stool, after which some relief is experienced. Pus and blood may sometimes be noticed with the excrecence, particularly when the disease has advanced to the ulcerated state. The patient at length becomes fallow, the constitution fuffers, and dissolution follows. Severe tenesmus attends the whole course of the disease.

Defaut has often seen the disease form a communication between the rectum and vagina, and the feces have passed through the latter part. In the latter stage of the affection, the rectum, bladder, vagina, uterus, and adjacent parts, are all involved in one common ulceration.

When the disease has attained the ulcerated state, it is probably always incurable. Palliative can now only be resorted to, such as anthine and emollient glyters, the warm-bath, &c. with the exhibition of medicines like opium, cictur, uva urpi, &c. Claudius applied his remedies to the infide of the bowel by means of tents, and did not employ the latter as a mode of curing the disease, when less advanced. Valsalva used to introduce a cannula pierced with numerous holes, when his patient got into the bath, so as to let the fluid enter the intestine. Numerous practitioners, among them Morgagni, made mercurials the base of their treatment, from a supposition that the complaint was of venereal origin.

When the disease is not attended with ulceration, the contraction and thickening of the gut may be diminished by introducing bougies, keeping them for a certain time, every day, so introduced, and increasing their size gradually. The preffure of these instruments seems to soften the disease, and stop its progression; a proof that its nature differs from that of what is usually understood by stricture. Defaut used to employ long tents, made of lint, smeared with cerarie, and piled into the bowel by means of a probe, with a forked end. This surgeon gradually increased the size of the tents, so as to continue the compression, to which he conceived all the good was owing. Their length was also augmented by degrees. Fresh ones were, at first, introduced twice every day. When any hardnesses were situated on the outide of the anus, Defaut cured them on the same principle, viz. by making proture on them with compresses and a bandage. This eminent surgeon effected a cure of a stricture-contrasted rectum by this method. The woman was taught to pass occasionally the tennis herself, so as to prevent a relapse. The disease is said to affect women more frequently than men: from a comparative table kept at the Hôpital-Dieu, this has been the case there in the proportion of ten to one. See *Œuvres Chirurgicales de Defaut*, tom. ii. p. 422.

**RECTUM, Hemorrhoidal Swellings of.** See Hemorrhoids.

**RECTUM, in Law.** See Recto.

**RECTUM, in our old Law Writers, is also used for a trial or accusation.**

**RECTUM, Commune, denotes a trial at law, or in the common course of law. Stare ad rectum, denotes to fland a trial. Rectum rogare, to petition the judge to do right.**

**RECTUS, in Anatomy, a name applied to several muscles, generally, but not invariably, distinguished by the straightness of their fibres, or of their general direction.**

**RECTUS abdominis.** See Obliquus.

**RECTUS abdominis, or externus.**

**RECTUS adductus, or internus.** { muscles of the globe of the eye. See Eye.}

**RECTUS depressor, or inferior.**

**RECTUS anterior cruris, or femoris.** { synonyms of the Rectus cruris; which fee.}

**RECTUS capitis anticus major et minor.** See Rectus internus.

**RECTUS capitis internus major, rectus anticus major, tracheo-laryngio-occipitien; a muscle of the head, flattened, broader and thicker above than below, occupying the anterior and lateral part of the neck, and reaching from the tranverse processes of the fifth cervical vertebra, to the inferior surface of the basilar process of the occiput. Its anterior surface is covered by the carotid artery, the internal jugular vein, the nerve of the eighth pair, the great sympathetic, and the pharynx. The longus colli, the rectus capitis internus minor, the articulations of the occipitum and atlas, and of the latter bone, and the second vertebra, are covered by its posterior surface. The inner edge lies on the longus colli, and is connected to it by cellular substance; the outer is fixed to the front of the cranial vertebrae, and from the spinal processes of the fifth cervical vertebra; it ascends with a little obliquity from without inwards, increasing in breadth and thickness: it approaches the muscle of the opposite side, and is attached by its upper end to the basilar process of the occipital bone, in front of the foramen magnum. At the upper part of this muscle is a broad and thin aponeurosis, which depends on the anterior and inner surface; the attachments to the transverse processes are by small tendons terminating in muscular portions. The muscular fibres run obliquely between the last mentioned tendons and the aponeurosis.

This muscle bends the head forwards on the neck; and restores it after it has been carried backwards. The muscle
of one side, acting singly, inclines the head towards its own side.

Rectus capitis internus minor, or rectus anticus minor, transchelous-occipitien; a small muscle of the head, lying under the ear, short, narrow, and flattened, and extending from the atlas to the occipit. It is covered in front by the rectus internus major, the internal carotid artery, and the great sympathetic nerve; behind it covers the capsule of the articulation between the atlas and occipit. The outer and inner edges present nothing remarkable. Its lower extremity is fixed to the anterior surface of the lateral portion of the atlas, and to the neighbouring part of its transverse process. Thence it ascends, increasing somewhat in size, and inclined a little inwards, and is fixed to the under surface of the bifidary process of the occipit, behind and a little on the outside of the rectus internus major, and to the cartilaginous mass filling the space between the occipital and temporal bones. It has aponeuroses at its extremities, and very short muscular fibres between these.

Its action on the head is exactly the same with that of the rectus internus major.

Rectus capitis lateralis, le premier transverse antérieur, Winnal, atlido-mastoïdien, petit droit latéral, a small muscle of the head, situated at the upper and lateral part of the neck, flattened and quadrilateral, reaching from the transverse process of the atlas to the occipit. It is covered in front by the internal jugular vein, and it covers behind the vertebral artery. The two edges present nothing remarkable. Below it is fixed to the front of the upper surface of the transverse process of the atlas; thence it ascends a little outwards, and is attached above to the rough impression behind the jugular fossa. It is muscular, except just at the attachments, which are tendinous. Its action, like that of the two half muscles, is to restore the head, when it has been bent backwards; to bend it forwards; and, when one muscle acts singly, to incline it laterally.

Rectus capitis posticus major, atlido-occipitien; a muscle of the head, of a triangular flattened figure, placed at the upper and back part of the neck, and extending from the spinous processes of the second cervical vertebra to the occipit. Its posterior surface is covered by the complexus, and above by the obliquus superior capitis; the anterior surface covers the posterior arch of the atlas, the rectus posticus minor, and the occipit. The inferior extremity, narrow, and almost pointed, is attached to the spinous processes of the second cervical vertebra, thence it ascends, directed outwards, and a little backwards, and gradually increasing in breadth, to be inserted in the inferior surface of the occipit, at about an equal distance from the great external transverse ridge, and the foramen magnum, between the complexus, the obliquus superior, and the rectus posticus minor. The extremities alone are tendinous; the rest being muscular. It restores the head, when it has been bent forwards; and carries it back on the vertebral column. When one muscle acts singly, it will have the power, from the oblique direction of its fibres, of rotating the head, so as to turn the face towards its own side.

Rectus capitis posticus minor, atlido-occipitien; a small flattened muscle with radiated fibres, and consequently a triangular figure, placed at the upper and back part of the neck, extending from the atlas to the occipit, and lying with its fellow in the interval between the two rectus major. Its posterior surface is inclined downwards and covered by the complexus; the anterior surface corresponds to the occipit, and to the interval between it and the atlas. The lower extremity is the narrow part, and is fixed to the rough impression in the middle of the posterior surface of the posterior arch of the atlas; it ascends parallel to the opposite muscle and directed backwards, and is fixed to the external surface of the occipital bone at a short distance from the foramen magnum. It raises the head when bent forwards; and extends it or carries it back on the neck.

Rectus cruris, rectus extensor or anterior cruris, droit, on grêle, antérieur, ileo-rutulien; a muscle of the thigh, long and flat, broad in the middle, and narrow towards its extremities, occupying the middle and front part of the limb, and reaching from the anterior and inferior spine of the ilium to the patella. It is covered in front by the iliacus internus, the vastorius, and the sartorius; being the obicular ligament of the hip, the great extensors of the knee, and the external or anterior circumflexus vessels. The outer and inner margins of the muscle are unattached in their upper three-fourths; they are confounded, in their lower fourth, with the extensors of the knee.

The superior extremity of the rectus cruris presents two tendons, one of which is straight, the other curved. The former is fixed to the anterior and inferior spine of the os innominatum: the latter, curved from before backwards, and from above downwards, is fixed to the outer surface of the os innominatum for about an inch, immediately above the edge of the acetabulum. From this upper attachment the muscle descends vertically in front of the thigh, growing broader to the middle of the limb; it then becomes narrow towards the lower part, and is fixed to the bones of the patella.

The rectus is tendinous in its extremities, and fleshy in the middle. The upper tendon has been already described as divided into two portions; the anterior of these, attached to the anterior and inferior spine of the os innominatum, is the thickest and shortest, and has the same direction as the muscle; the other is longer and curved, and detaches some fibres to strengthen the obicular ligament of the hip. The two portions then unite in a common tendon, this spreads out into a broad aponeurosis, which descends about four inches on the front of the muscle, and then dips into its substance. The inferior tendon is broad and flat, and rises from the bones of the patella; its posterior surface is united to the great extensors of the knee, and the edges are strongly connected to the vastus externus and internus. It is broad at the patella, grows a little narrower as it rises, then spreads out again, and forms a broad aponeurosis, covering the back of the muscle above its middle. The superficial fibres of this tendon descend over the front of the patella, to which they are strongly united, and are left below in the tendon which unites this bone to the tibia. The muscular fibres are placed very obliquely between the superior and inferior tendons: they cover the back of the foot up to the part where its two portions separate; and they descend on the front of the second to within two inches of the patella.

It extends the knee-joint, either by bringing the leg forwards upon the thigh, or the thigh upon the leg, as the one or the other part is rendered a fixed point. If the knee be extended, or firmly retained in the bent position by its flexor muscles, the rectus may bend the thigh upon the pelvis: when the leg and thigh are fixed, it can bend the pelvis forwards upon the latter, as in the attitude of stooping to pick up any object from the ground. In the erect attitude it prevents the pelvis from inclining backwards; and renews it when it has been carried in that direction.

Rectus in curia, in Lavo, one who stands at the bar, and no man objects any thing against him.
When a man hath revered the outlawry, and can participate of the benefit of the law, he is said to be relictus in curia.

RECULVER, in Geography, a village and parish in the upper half-hundred of Blean-Gate, latitude of St. Augustine, and county of Kent, England, is situated at the distance of 10 miles N.E. by N. from Canterbury. It is noted in history as the site of the Roman Regulbi, the Itnion or castle which defended the northern entrance to the celebrated Portus Rutupiensis. It is remarkable, that while the ocean has receded from the southern entrance, leaving Richborough (Rutupium) considerably inland, it has gradually advanced upon Reculver. This is proved on the authority of several ancient writers, particularly Leland, who states, that in his time it flowed about half a mile from the shore, whereas, at present, the tide washes the walls of many of the village houses, and threatens to overwhelm the whole at no distant period. Regulbi was a Itnion of much importance, as it not only commanded an extensive view of the open sea, but likewise of the mouths of the Thames and the Medway. It was therefore used as a watch-polt to discover the approaches of an enemy; and also as a light-house to guide sailors. In its perfect state the Itnion was of a square form, with the angles rounded off, and was environed by a ditch exterior to the walls, of which a considerable portion still remains. The extent of the enclosed area from east to west is about 190 yards, and from south to north about 198 yards. The ancient town was without the Itnion, and is supposed to have flood towards the north, on that part of the coast long since swallowed up by the waves. It and from the present shore, as far as a place called Black Rock, seen at low water mark, where, according to tradition, a church once stood, there have been found great quantities of tiles, bricks, fragments of walls, tessellated pavements, and other marks of a ruined town, and remains of the household furniture, drefs and equipment of the horses belonging to its inhabitants, are continually met with among the sands; for after the fall of the cliffs, the earthen parts of them being washed away, these metallic substances remain behind. 1 When a part of the cliff here fell down about the conclusion of the seventeenth century, a number of small vaults, arched over, and several citizens, were discovered. The latter were all of the same figure, namely, square, and measured from ten to twelve feet in length each side, and the same in depth. They were constructed of poles, driven deep into the ground, with planks two inches thick fixed to them. Their use was evidently the reception and preservation of rain water, which the Romans thought more wholesome than spring water. Vast quantities of Roman coins have been discovered both in the fields and along the shore here; and Du Ferne has produced many, which, from the markings upon them, appear to have been struck at a mint in this place. Britifh and Gaulish coins are likewise occasionally found here; also seals, keys, spoons, gold rings, bracelets, figulze, bullze, belts, bridles, harnesses, beams of scales or billiards, and many other articles of which the use has not yet been determined.

When Kent was subdued by the Saxons, Regulbiurn became a principal seat of the monarchs of that dynasty. It was then called Raculf and Raculf-cefel; and hither king Ethelred retired with his court, after his conversion to Christianity by St. Augustine. In the next century it obtained the name of Raculf-minster, from a Benedictine abbey founded here by Baffa, a priest and nobelman, to whom lands were granted for that purpose by king Egbert, as an atonement for the murder of his two nephews. This abbey was dissolved previous to the Conquill, having probably been destroyed by the Danes. The town, however, continued in a flourishing condition for many years after that event, and had the privilege of a weekly market granted to it in 1315; but this right has been long discontinued. The church here is an ancient and spacious edifice, consisting of a nave, with two aisles, a chancel, and two lofty towers, surmounted by spires at the angles of the west front. The nave is separated from the aisles by five pointed arches, rising from short oblong piers; and from the chancel by three small semi-circular arches, springing from tall round columns, with very singular capitals. In this church kings Ethelbert I. and II. are said to have been buried; and a monument erected to the memory of the first is described by Wheeler in his "Funeral Monuments," though it has now disappeared. On the floor of the chancel are several brasses of great antiquity. (See Richborough.)

RECUMPAKO, in Geography, a town of Hindoostan, in the circar of Rajamundry; 23 miles N.W. of Rajamundry. RECUPERATORS, among the Romans, were commilcnners appointed to take cognizance of private matters in dispute, between the subjects of the state and foreigners, and to take care that the former had justice done them. It came at last to be used for commilcnners, to whom the praetor referred the determination of any affair between one subject and another.

RECURRENS, in Anatomy, a name under which the inferior laryngeal branch of the par vagum is often described, from the circumstance of its ariling in the chin below the point of its distribution to the larynx, and then going back into the neck in a retrograde course. See NERVE.

RECURRING SERIES, is a series so conluclcd, that each succeeding term is connected with a certain number of the terms immediately preceding it, by a certain and invariant law; as the sums or differences of some multiples of those terms. Thus the series

\[ a, \beta, \gamma, \delta, \epsilon, \theta \text{ &c.} \]

is a recurring series; for these terms being respectively represented by \( a, \beta, \gamma, \delta, \text{ &c.} \), we have

\[ \gamma = 2 \times \beta - \alpha \]
\[ \delta = 2 \times \gamma - \alpha \]
\[ \epsilon = 2 \times \delta - \alpha \]
\[ \theta = 2 \times \epsilon - \alpha \]

that is, each term is equal to \( 2 \times \) times that which precedes it, minus \( \alpha \) times the one preceding the last.

Or, generally, let

\[ a, \beta, \gamma, \delta, \epsilon, \theta \text{ &c.} \]

be any series whose terms are denoted as above, by \( a, \beta, \gamma, \delta, \text{ &c.} \). Also, let \( \mu, \nu, \rho, \sigma, \text{ &c.} \) represent the successive multipliers by which the terms are connected, so that

\[ a = a \]
\[ \beta = \beta \]
\[ \gamma = \mu \times \beta + \nu \times \alpha + \text{ &c.} \]
\[ \delta = \mu \times \gamma + \nu \times \beta + \text{ &c.} \]
\[ \epsilon = \mu \times \delta + \nu \times \gamma + \text{ &c.} \]
\[ \theta = \mu \times \epsilon + \nu \times \delta + \text{ &c.} \]

then this series is called a recurring series; and \( \mu + \nu + \text{ &c.} \) Do Moivre calls the scale of relation, which is said to be of one, two, three, &c. terms, according to the number of multipliers

\[ \frac{3Z2}{2} \]
RECURRING SERIES.

Multiples by which it is connected. In the above we have used only two, \( \mu \) and \( \psi \), whence \( \mu + \psi \) is called the scale of relation, which is here of two terms; and \( \psi \) minus the scale of relation, as \( 1 - \mu - \psi \), is called by the same author the differential scale, which is always equal to the denominator of the fraction from which the series is produced.

If, in the above series, the terms had the relation

\[
\begin{align*}
\alpha &= x \\
\beta &= \beta \\
\gamma &= \gamma \\
\epsilon &= \mu x + \gamma + x^2 + \beta + \epsilon x^3 \\
\iota &= \mu x + \beta + \gamma + x^2 + \epsilon x^3 \\
\theta &= \mu x + \beta + \gamma + x^2 + \epsilon x^3
\end{align*}
\]

then the scale of relation would be \( \mu + \psi + \gamma + \epsilon \), which is of three terms; and the differential scale, or the denominator of the fraction, is \( 1 - \mu - \psi - \gamma \).

The following problems are naturally connected with the doctrine of recurring series; viz.

1. Any recurring series being proposed, to find the scale of relation, or the law of the series, which is not always obvious on inspection.

2. To find the sum of an infinite recurring series, or the sum of any number of its terms \((n)\).

3. To find a general expression for any indefinite term of such a series, as, for example, the \( nth \) term.

We shall consider each of these problems under their separate heads.

1. To find the scale of relation in any proposed recurring series.

Let \( x, y, z, u, v, \&c. \) be a recurring series, of which it is required to find the scale of relation.

Assume

\[
\begin{align*}
\beta &= \beta' + \gamma + \epsilon + \&c. \\
\iota &= \iota' + \gamma + \epsilon + \&c. \\
\theta &= \theta' + \gamma + \epsilon + \&c.
\end{align*}
\]

Where \( \beta, \gamma, \epsilon, \&c. \) are known, and \( \beta', \gamma, \epsilon, \&c. \) unknown quantities, whose numeral values are required, and which are readily found by the usual method of elimination. Thus in the above, using only \( \mu \) and \( \psi \), we have

\[
\begin{align*}
\mu' &= \frac{\beta - \gamma - \epsilon}{\psi} \quad \text{and} \\
\psi' &= \frac{\beta - \gamma - \epsilon}{\psi}
\end{align*}
\]

These values of \( \mu' \) and \( \psi' \), will obviously contain in them the powers of the indeterminate quantity \( x \), which having been taken out, we shall have the required numeral values of \( \alpha \) and \( \beta \).

Let it be required to ascertain the scale of relation in the series

\[
\begin{align*}
\alpha &= a \\
\beta &= \beta \\
\gamma &= \gamma \\
\lambda &= \lambda \\
\lambda &= \lambda \\
\psi &= \psi \\
1, 5, 5, 5, 1, 9, 9, 9, 9, \&c.
\end{align*}
\]

Here, by substituting the proper values of \( \alpha, \beta, \gamma, \&c. \) in the above equation, we have

\[
\begin{align*}
\mu' &= \frac{25 x^2 - 27 x^3}{26 x^2 - 21 x^3} = \frac{8 x^3}{2 x^3} = 2 x \\
\psi' &= \frac{45 x^3 - 45 x^4}{21 x^3 - 25 x^4} = \frac{4 x^4}{4 x^4} = 1 x
\end{align*}
\]

when \( \mu = 2 \), and \( \psi = -1 \).

The same method may obviously be employed in any other case; but in order to know whether or not we have assumed a scale of relation of a sufficient number of terms, we must repeat the same operation upon the three other terms, of which one at least was not before employed; and if both the same values, we may assume the truth of our results; or we may otherwise, instead of repeating the operation, examine the several terms, and see whether they agree with the law we have determined, and if not, we must increase the terms in our scale of relation; for it may be observed, that we can never fail of determining them in consequence of having assumed too many terms, as we shall, in that case, have one of our results zero.

La Grange has formed a different rule for ascertaining whether a given series be recurring or not, which Mr. Bonycastle has given at p. 323 of his Algebra; but as it does not seem adapted for detecting the law of formation, we shall not insert it.

11. To find the sum of any recurring series, of which the scale of relation is known.

Let

\[
\begin{align*}
\alpha &= a, b, c, e, d x^2, e x^3, f x^4, \&c. \\
\beta &= \beta \\
\gamma &= \gamma \\
\lambda &= \lambda \\
\lambda &= \lambda \\
\psi &= \psi \\
\&c. \quad \&c. \quad \&c.
\end{align*}
\]

be a recurring series, of which the scale of relation is

\[
\begin{align*}
\mu &= \mu + v + \psi \\
\beta &= \beta \\
\gamma &= \gamma \\
\lambda &= \lambda \\
\lambda &= \lambda \\
\psi &= \psi \\
\&c. \quad \&c. \quad \&c.
\end{align*}
\]

Here it is obvious, that the whole sum

\[
S = \alpha + \beta + \gamma + \lambda + \psi + \&c.
\]

\[
S = \alpha + \beta + \mu x (\beta + \gamma + \lambda + \psi + \&c.) + v x^2 (\alpha + \beta + \gamma + \lambda + \psi + \&c.)
\]

\[
S = \alpha + \beta + \mu x (S - \alpha - \beta) + v x^2 (S - \alpha - \beta)
\]

whence we have

\[
S = \frac{\alpha + \beta + \gamma - \mu x (\alpha + \beta) - v x^2}{1 - \mu x + v x^2 - \psi x^3}
\]

which is a general expression when the scale of relation is of two terms.

When the scale of relation is of three terms, so that

\[
\begin{align*}
\alpha &= a, b, c, e, d x^2, e x^3, f x^4, \&c. \\
\beta &= \beta \\
\gamma &= \gamma \\
\lambda &= \lambda \\
\lambda &= \lambda \\
\psi &= \psi \\
\&c. \quad \&c. \quad \&c.
\end{align*}
\]

it is equally obvious that

\[
S = \alpha + \beta + \gamma + \lambda + \psi + \&c. + v x^2 (S - \alpha - \beta) + v x^2 (S - \alpha - \beta)
\]

whence we have

\[
S = \frac{\alpha + \beta + \gamma - \mu x (\alpha + \beta) - v x^2}{1 - \mu x - v x^2 - \psi x^3}
\]

which is the general expression for the sum, when the scale of relation is of three terms.

In the same manner we have

\[
S = \alpha + \beta + \gamma + \lambda - \mu x (\alpha + \beta + \gamma) - v x^2 (S - \alpha - \beta) - \psi x^3
\]

for a scale of relation of four terms; and so on.

But as the terms \( \alpha, \beta, \gamma, \&c. \) contain in them certain powers of \( x \), we may reduce the above expressions to simpler forms.
RECURRING SERIES.

III.—To find the general term of any proposed recurring series.

From the preceding part of this article it appears, that every recurring series may be considered as arising from the development or expansion of some rational fraction of the form

$$\frac{a + bx + cx^2 + dx^3 + \&c.}{1 - x - 2x^2 - 3x^3 - \&c.}$$

Let us, therefore, suppose this fraction to be converted into the infinite recurring series \(A + Bx + Cx^2 + Dx^3 + \&c.\), of which we already know how to determine the co-efficients, and the law of their formation.

Now if this rational fraction be decomposed into its simple fractions by the method explained under the article RATIONAL FRACTIONS, and each of these simple fractions be then converted into a recurring series, it is evident that the sum of all these series ought to be equal to the original series

$$A + Bx + Cx^2 + Dx^3 + \&c.$$ 

Now each of these partial fractions being of the form

$$\frac{a}{1 - rx}$$

the series thence arising will have the form

$$A' + A'rx + A'r^2x^2 + A'r^3x^3 + \ldots$$

of which \(A'r^n\) is the general term. Hence, the several series arising from the partial fractions may be supposed to be

$$A' + A'r + A'r^2 + A'r^3 + \ldots = A'r^n$$
$$A'' + A''r + A''r^2 + A''r^3 + \ldots = A''r^n$$
$$A''' + A'''r + A'''r^2 + A'''r^3 + \ldots = A'''r^n$$
$$\ldots$$

and since the sum of these series is equal to the original one proposed, we know that the co-efficients of the like powers of \(x\) are also equal, whence we have

$$A = A' + A'' + A''' + \&c.$$ 
$$B = A'r + A''r + A'''r + \&c.$$ 

wherein it appears that the co-efficient of any term \(x^n\) of the recurring series is equal to the sum of the co-efficients of the same power of \(x\), which arise from expanding the several simple fractions into which the given fraction is decomposed; and this co-efficient is always equal to the sum of each of the numerators of the several simple fractions, multiplied into the \(n\)th power of the corresponding value of \(r\) in the denominator of the same fraction, at least while the denominator contains no equal factor. But if, among the partial fractions, there is any one of the form \(\frac{A'}{1 - (r)x}\), the general term of this will be \((n + 1)A'r^n\) of \(\frac{A}{1 - (r)x}\), the general term is \(\frac{(n + 1)(n + 2)}{1 \cdot 2 \cdot 3 \ldots (k - 1)}\), the general term is

$$\frac{(n + 1)(n + 2)(n + 3) \ldots (n + k - 1)}{1 \cdot 2 \cdot 3 \ldots (k - 1)}$$

we may, therefore, in all cases wherein the generating fraction of the original series admits of a rational decomposition, arrive very readily at the general term upon the principles above explained.

Thus,
RECURRING SERIES.

Thus, as an example, let there be proposed the recurring
series

\[ 1 + 4x + 14x^2 + 46x^3 + 146x^4 + \&c. \]
to find the general term, or the co-efficient of \( x^n \).

The sum of this series is found by the preceding part of this article to be
\[ \frac{1 - x}{1 - 5x + 6x^2}. \]

This rational fraction is equal to \( \frac{-1}{2 - 2x} + \frac{2}{1 - 3x} \). Now
the general term of
\[ \frac{1}{1 - 2x} \]
is \( 2^n x^n \); and of \( \frac{2}{1 - 3x} \)
is \( 2 \cdot 3^n x^n \), as shown above, therefore the general term of the proposed series will be \( (2 \cdot 3^n - 2^n) x^n \).

It may be observed, however, that this method is in some cases very laborious, and not always practicable; it will, therefore, frequently be better to make use of the multinomial theorem, which may be done by putting the generating fraction under the form

\[ (x + bx + cx^2 + \&c.) \]

\[ (1 - ax - bx^2 - \gamma x^3 - \&c.)^{-1}. \]

See Multinomial Theorem.

IV.—To find the sum of any number \( n \) terms of a recurring
series.

For this purpose it is only necessary to find the co-efficient of the \( n + 1 \)th term of the series. Then, from the sum of the entire series subtract the sum of the series beyond the \( n \)th term, and the difference will obviously be the sum of the first \( n \) terms sought.

Let there be proposed as an example to find the sum of \( n \) terms of the series

\[ 1 + 2x + 3x^2 + 4x^3 + \ldots n x^{n-1}. \]
The infinite sum of this series is readily found \( = \frac{1}{(1 - x)^3} \).

In the second case, viz., of the terms beyond \( n x^{n-1} \), the series is

\[ \frac{(n + 1) x^n + (n + 2) x^{n+1} + (n + 3) x^{n+2} + \&c.}{(1 - x)^3} \]
and in the formula
\[ s = \frac{\alpha + \beta - \alpha \mu x}{1 - \mu x - \gamma x^2} \]
we have only to substitute \( \alpha = (n + 1) x^n \) and \( \beta = (n + 2) x^{n+1} \), instead of \( \alpha = 1 \) and \( \beta = 2 n x^n \) as in the former. Hence we have

\[ s' = \frac{(n + 1) x^n + (n + 2) x^{n+1} + (n + 1) x^{n+2}}{1 - 2x + x^2} \]
or

\[ s' = \frac{(n + 1) x^n - nx^{n+1}}{(1 - x)^3}; \]
and, therefore, \( s - s' \), or the sum of the first \( n \) terms is equal to

\[ \frac{1 - (n + 1) x^n + nx^{n+1}}{(1 - x)^3}. \]

2. Required the sum of \( n \) terms of the series

\[ 1 + 3x + 5x^2 + 7x^3 + \ldots (2n - 1) x^{n-1}. \]

Here, by trial, we find the scale of relation to be \( \mu + 2 \), and \( r = -1 \), as before, therefore the infinite sum is

\[ s = \frac{\alpha + \beta - \alpha \mu x}{1 - \mu x + x^2} = \frac{1 + x}{1 - 2x + x^2} \]

After \( n \) terms, the series becomes

\[ \frac{(2n + 1) x^n + (2n + 3) x^{n+1} + (2n + 5) x^{n+2} + \&c.}{(1 - x)^3}. \]

which therefore arises from the fraction

\[ \frac{(2n + 1) x^n + (2n + 3) x^{n+1} - 2 (2n + 1) x^{n+2}}{1 - 2x + x^2} \]

whence the sum of \( n \) terms is

\[ \frac{1 + x - (2n + 1) x^n + (2n - 1) x^{n+1}}{(1 - x)^3}. \]

3. Required the sum of \( n \) terms of the series

\[ (n - 1) x + (n - 2) x^2 + (n - 3) x^3 + \&c. \]

Here again the scale of relation is \( + 2 - 1 \), therefore the infinite sum is

\[ \frac{(n - 1) x + (n - 2) x^2 - 2 (n - 1) x^3}{(1 - x)^2} \]

After \( n \) terms, it becomes \( - x^{n+1} - 2 x^{n+2} - \&c. \), the sum of which is found in the same manner to be \( \frac{-x^{n+1}}{1 - x} \); therefore \( n \) terms of the proposed series is

\[ \frac{(n - 1) x - nx^2 + x^{n+1}}{(1 - x)^2}. \]

Hence, also, \( n \) terms of the series

\[ \frac{(n - 1) x + (n - 2) x^2 + (n - 3) x^3 + \&c.}{(1 - x)^3} \]

is found to be

\[ \frac{1 + x - (n + 1) x^n + (2n + 2 + 2n - 1) x^{n+1} + n! x^{n+2}}{(1 - x)^3}. \]

the scale of relation being \( 3 \cdot 3 \cdot 1 \).

In all the preceding examples we have determined the infinite sum of the series, as beginning at the \( n \)th term, and at the \( (n + 1) \)th term, a more easy method is as follows, which is due to Simpson. Effays, p. 96.

Let \( A + B + C + D + \ldots + K + L + M + N \) be any finite recurring series, of which each term depends upon the three which precede it, the scale of relation being \( p, q, r \), so that

\[ \rho A + q B + r C = D \]
\[ \rho B + q C + r D = E \]
\[ \&c. \]

or, which is the same,

\[ \rho A + q B + r C = D = 0 \]
\[ \rho B + q C + r D = E = 0 \]
\[ \rho C + q D + r E = F = 0 \]
\[ \&c. \]
\[ \rho K + q L + r M = N = 0 \]

whence,
where, by addition

\[ f(A + B + C + \ldots + K) + q(B + C + D + L) = 0 \]

\[ r(C + B + D + \ldots + M) - (D + E + F + N) = 0 \]

Or, representing the whole sum by S,

\[ \rho(S - L - M - N) + q(S - A - M - N) + r(S - A - B - C) = 0 \]

which, by addition and division, gives

\[ f(L + M + N) + q(A + M + N) + r(A + B + C) \]

\[ S = \rho + q + r - 1 \]

where the sum depends merely upon the three first and the three last terms of the series; and a similar expression, it is obvious, may be obtained for any other scale of relation.

It may not be amiss to observe, that when the proposed series is wholly numeral, (the sum of which, as we have before observed, is to be found by making \( x = 1 \)) both this formula and the preceding one fail, in the case in which the denominator of the fraction becomes zero, and we must, therefore, in such cases, have recourse to other methods of summation, as given under the article Series.

On this subject the reader should consult De Moivre's Mice. Analyt. and his Doctrine of Chances, and Euler's Analyt. Infinitorum, where he will find an explanation of its application to the approximation to the roots of equations. Collon's Comment on Newton's Fluxions. Stirling's Methodus Differ. Cramer's Analyt. des Lignes Curbes. Bernoulli de Sereb. Inf. &c. See also a chapter on this subject, in vol. ii. of Bonneycastle's Algebra.

RECURVOSTRA, the Avocet, in Ornithology, a genus of birds of the order Grallæ, of which the generic character is; bill depressed, tubulate, recurved, pointed, flexible at the tip; the feet are palmate, four-toed, the hind toe not connected, very short, and placed high up; the nostrils are narrow, pervious; the tongue is short. There are only three species.

*Avocetta;* Scooping Avocet; called also in different parts of this country, butter-slip, lepocer, yelver, crooked-bill, &c. This bird is variegated with white and black; the bill is three inches and a half long; irides hazel; crown black; a white spot behind and beneath the eyes; reed of the head, neck, back, exterior part of the wings, lesser quill-feathers, tail, and under part of the body, white; inner scapulars and greater quill-feathers without and at the tips black; legs blueish, and very long; membrane connecting the toes indented. It reeds in the temperate parts of Europe, weighing thirteen ounces; and measuring, from the tip of the bill to the end of the tail, eighteen inches. It breeds in the fens of Lancashire, and in the county of Lincolnshire, in Kent. The female lays two white eggs, tinged with green, and marked with large black spots. In winter these birds assemble in small flocks of six or seven, and frequent the shores, particularly the mouths of large rivers, in search of worms and marine insects, which they scoop out of the mud or sand. They seem to be particularly fond of the cancer, plexus, or locusts. By means of their long legs, they run over shores that are covered five or six inches with water. In their movements they are lively, alert, volatile, and difficult to catch. When the female is frightened off her nest she counterfeits lameness; and when a flock is disturbed, they fly with their necks stretched out, and their legs extended behind, over the head of the spectator, making a shrill noise, and uttering a yelping cry of twit, twit, all the time.

**American Avocet.** The head and neck are reddish; back black, beneath it is white. It inhabits North America and New Holland; is fourteen inches long. Bill black; front dull-dull white; neck above white; primary and tertial wing-coverts black, the middle ones, and some of the secondary quill-feathers, white.

**White Avocet.** This species is white; the lower wing-coverts brownish; bill orange; legs brown. Inhabits Hudson's Bay; fourteen inches and a quarter long. Bill tippets with black; edge of the wings, greater quill-feathers, and tail, tinged with yellowish.

RECURSANTS, in a general sense, perfons, whether Papists or others, who refuse to go to church and to worship God after the manner of the church of England. Popish recusants are Papists, who do refuse; and a papish recusant convicted is a Papist legally convicted of such offences. See Papists, Prelates, and Toleration.

**Recusation, Recusatio,** an act by which a judge is deputed to refrain from judging some certain cause, on account of his relation to one of the parties; or of some capital enmity, or the like.

By the French laws, kinship within the fourth degree is deemed a legal cause of recusation; as also the judge's being godfather, &c. of one of the parties.

By the laws of England also, in the times of Bruton and Fleta, a judge might be refused for good cause; but now the law is otherwise, and it is held that judges or justices cannot be challenged. Co. Litt. 254. See Challenge.

**RED,** in Physics, one of the simple or primary colours of natural bodies, or rather of the rays of light.

The red rays are those which are of all rays the least refrangible; hence, as Sir Isaac Newton supposes the different degrees of refrangibility to arise from the different magnitudes of the luminous particles of which the rays consist, the red rays, or red light, is concluded to be that which consists of the largest particles. See Colour, Light, and Ray.

Authors distinguish three general kinds of red; one bordering on the blue, as cobaltine, or dove-colour, purple, and claret; another bordering on yellow, as flame-colour and orange; and between these extremes is a medium, partaking neither of the one nor the other, which is what we properly call red.

Acids generally turn black blue, and violet into red; and red into yellow, and yellow into a very pale yellow.

Alkalies change red into violet, or purple; and yellow into feuillemort, or dead leaf-colour.

Terrestrial and sulphureous matters become red by extreme heat; and some, at length, black, as we see in brick, red bolt, red chalk, flaxe, &c. All these, when vitrified by a burning-glass, become black.

Lobsters become red by a moderate fire; and by a violent one, black. Mercury and sulphur mixed and heated over a moderate fire make a beautiful red, called artificial zinnabas.

An acid spirit, as lemon juice, being poured on a blue solution of turpentine, turns it into a beautiful red. Alkali restores it again to its original blue. Diluting of some reddish wines takes from them all their red colour.

M. de la Hire observes, that a very luminous body viewed through a black one, always appears red; as when the sun is seen shining through a black cloud. He adds, that some people who see all the other colours perfectly well, yet have no idea of red, and only see it as black.

**RED,** in Cosmatics, a focus or paint with which the ladies enliven their cheeks and lips.
There are two kinds of reds; the one in leaves, called Spanish red; the other a liquor, which is an extract of a scarlet dye.

**Red**, in **Dyeing**, is one of the five simple or mother colours of the dyers. Some reckon seven kinds, or calls of red: 
- **Scarlet**-red, crimmon-red, madder-red, half-grain-red, half-crimmon-red, lively orange-red, and scarlet of cochineal. But they may be all reduced to three, according to the three principal drugs which give the colours; which are kermes, cochineal, and madder.

The fine scarlet, called **scarlet of the Gobelin**, is given with a garic, bran-water, woad, and scarlet grain, or kermes. Some dyers add cochineal, and others fenugreek; brightening it with bran-water, a garic, tartar, and turmeric. See **Kermes** and **Scarlet**.

Crimson-red is dyed with bran-water, tartar, and melleque cochineal. See **Crimson**.

Madder-red is dyed with madder; to which some add realgar, or red arsenic; others, common salt, or other salts, with wheat-flour; or a garic with spirit of wine, with galls or turmeric. See **Madder**.

The half-grain is made with a garic and bran-water, half scarlet grain, half madder, and sometimes turmeric.

The half-crimmon is made of half madder, half cochineal. As to the lively orange-red, the fluid must be first put in yellow, then in a liquor made of goat's hair, (which has been boiled several times with madder) diffused over the fire with certain balm liquors, as urine, tartar, &c.

The scarlet of cochineal, or Dutch scarlet, as the French call it, is made with mitrech, tartar, and cochineal; after it is boiled it with alum, tartar, galima, and aqua fortis, in which pewter has been diffused.

Besides these seven reds, which are good and allowed colours, there is also a **Brazil red**, which is discouraged, as fading easily.

Of the seven good reds, only four have particular calls, or shades; the madder-red, crimmon-red, lively orange-red, and scarlet of cochineal.

The calls or shades of crimmon are flesh colour, peach colour, carnation rose colour, and apple-tree flower colour. Those of madder are flesh colour, onion-peel colour, and flame colour. Those of orange are the same with those of crimmon. Scarlet, besides the shades of all the red, has some peculiarity to itself, as cherry colour, fire colour, &c.

**See Dyeing**.

**Red**, in the **Manufacture of Glass**. See **Red Glass**.

To make a deep red in glass, the following method is that most practiced by the glass-men. Take crystal frit twenty pounds, broken pieces of white glass one pound, calcined tin two pounds; mix these well together, and put them into a pot to melt and purify. When these are melted, take lead calcined, scales of iron from the smith's anvil, both powder very fine, of each an equal quantity; put lefurly an ounce of this mixed powder to the before mentioned metal; mix all well together, and let them stand six or eight hours in fussion to incorporate; take out a proof after this, and if there be too little of the powder, it will appear of a dulky yellow; then more of the powder must be added, and then add three quarters of an ounce of calcined brafs, ground to a fine powder; mix them thoroughly together, and the mass will be of a blood red; continue tarring the whole together, and frequently taking out proofs of the colour, when it is right, work it immediately, otherwise it will lose its colour and become black. The mouth of the pot must in this process be left open, else the colour will be lost. *Neri's Art. of Glass*, p. 100.
are yet wet. The operator is to provide a glass pipe, and covering one end of it with a piece of fine gauze, he is to dip this into the powder, and taking it carefully out, with what little is flicking to it, he is to blow against the vessel at some distance from it; thus the finest part of the powder only will reach the vessel, and will be laid on in form of glittering spangles, very small, but all distinct. This is a sort of colouring much esteemed by the Chinese themselves, and they have a way of using the common blue in the same manner; but few of the vessels thus painted come over to us.

Red Clover, in Agriculture, an useful artificial graft for arable lands. It has this name in contradistinction to the white and some other sorts. There were at first many and very great prejudices against and objections made to the introduction of this plant into cultivation by farmers, which were not surmounted without difficulty, and it prevailed for some length of time in particular districts, as Staffordshire and Worcestershire, before it was known in some other counties, where it is now very predominant and beneficial, as Cheshire, Lancashire, and many more.

In some arable counties red clover is found to fail as a crop when long cultivated, dying away in the winter and spring, which the farmers designate by saying that the land is sick of it. This is a severe inconvenience to them in many cases; and renders such variations in the courses of cropping necessary, as may prevent the recurrence of it so frequently as has hitherto been the case. It is very liable to fail in every part of the county of Essex, but of the cause of which there are different opinions, some thinking that the land becomes sick of the plant, while others do not attribute it to any fatigue of this nature, but alter their modes of cropping that it may not take place so often. About the Belcamps and Boley this is very much the case, some venturing it only in seven years, and in that case it succeeds well. In all the Tending hundred it is said to decline little on the strong rich lands, but it is felt on the lighter sorts; on both the cropping is varied in regard to it. In the neighbourhood of Thorndon the lands are sick of it. And at Audley End the land is tired of it, but more in many cases from want of sufficient feed than any other thing else. In the vicinity of Hal-lingbury it is very liable to fail, if sown oftener than once in seven or nine years, though the sylph thereabouts is crop and fallow.

In the county of Oxford some sow red clover twice in ten years, the land being new to it; of course it never fails. On the gravelly loamy soils about Henly it dies from repetition, so that it is alternately omitted in cropping, others being subject, as white clover, trefoil, and pears. Nothing of this sort was known forty years ago, but now they sow it only once in two years. The loams and stony-braided lands around Wood Raton are not in general tired of this plant; some however find it to fail on the latter sort of soil. About Great Tew, where the lands have been included forty years, they are not yet tired of red clover. At Atterbury, where the lands have been included more years, it does not now succeed quite so well as it did fifteen or twenty years ago. In these failures other crops are put in, as tares and early peas drilled.

Some suspect sheep's dung to be destructive to the red-clover plant, but there are no proofs of the fact.

The most proper management of red clover as a preparation for wheat is a matter of great importance. Some think feeding it off wholly the best practice; others mowing and feeding; and a few mowing altogether. The method of feeding off the crops altogether, when done in a close even manner, is probably the most advantageous in this intention, though there may be some immediate loss of convenience; after which that of mowing the first crop and feeding the second in a useful manner; the third mode, or that of mowing twice, is most to be feared, but upon some sorts of land it may be done and answer well for wheat. These methods are all practised and have their advocates in different parts of Essex; and some think that they get as good wheat after white as red clover, as well as that feeding the latter does no injury in this respect.

The farmers in Oxfordshire follow nearly the same practices, and hold much the same opinions in regard to the management of this crop as a preparation for wheat. And the custom of feeding and mowing the first year, is thought the best practice in some other counties.

But in the county of Lancashire, and some others adjoining it, they know nothing of the land being ever sick or tired of this sort of crop, though they grow it in more frequent succession and in a more full manner than perhaps any where else in the kingdom. Ask the farmers about this, from one end of the above county to the other, they are all of the same opinion, and appear much surprized at the question, not ever having any conception of such a circumstance. What can be the reason that red clover has been as long and as frequently cultivated in these districts, as in those where it is so liable to fail? Does it depend upon the difference-in the nature or quality of the soils, or the management in regard to the quantity of feed and other matters? The circumstance is worthy of further and more close attention and investigation, in consequence of its great importance to the farmer.

There is one particular feature of management in the cultivation of red clover in the county of Oxford, which is that of hand-fowing over it from fourteen to fifteen bushels of Newbury peat-a-shre, that are brought into the Thames, by the Reading canal, on the acre, about the end of Febrary or the beginning of the following month; which has an immediate effect upon it, seldom failing to produce a crop, except where it naturally declines. The expense is estimated at about ten shillings the acre. These alas do not, however, seem to be employed in this way to the red clover crop in the district where they are found and prepared.

Seeded red clover undergoes two succedaneous seedings, the first, which only beats off the heads and chaffs containing the feed from the stalks, is called cobbing in some places; the parts thus separated being denominated the red-clover cob. The work is performed on a thick wooden plank frame for the purpose, and requires much labour to separate the feed, which, when done, is cleaned and passed through different sieves, being ultimately divided into two sorts, the primary and secondary. The cott of these operations is very great, amounting to from four to fix shillings the bushel, and sometimes much more. It has been concluded by Mr. Middleton, that this plant grows a full crop in all the arable lands of this country, from the sands of Norfolk to the clays of Cleve-land and Suffex. And that various soils that have been exhaufted by corn, and not much accustomed to red clover, have been so much restored by it, as to produce a good crop of wheat; but that to do this every means should be used to secure a full crop, as that is an excellent preparation for corn, and seldom fails of ensuring a considerable produce, arling from shade, snoter, and putrefaction, the natural and contented attendants of full-grown red clover. It is supposed advisable, in some cases of poor land, to feed both crops off on the land by sheep and other animals, in some way or other. And sometimes to mow the first and feed the second, or the contrary. In every point of view this is an interesting plant to the farmer. See Clover.
RED

Red Gum, an infect disease on wheat, by which the ears of the grain are deprived of their nutrition, and thereby prevented from perfecting themselves. It is described by Mr. Middleton to be a collection of insects, which are visible to the unaided eye, and which, in the early part of their growth, are of a reddish colour, but become brown with age: the black spots on the straw, blades, and ears of the wheat, are supposed to be the excrement of the insects. The blighted ears are probably rendered so, by the insects piercing the necks of the straw immediately below them, and sucking the sap of the plant, otherwise defined for filling the corn. In those ears which have both perfect and imperfect grains, the insect has perhaps infected its host at the connection between the corn and the straw, and by drinking up the food of the grains severally, has killed many of them in such a manner as to cause their destruction and decay. The exact nature of the disease is not, however, yet well ascertained.

Red Hay, a term used to signify such as is mow-burnt, in opposition to such as is green from a moderate heat, and winny hay, or such as is mouldy.

Red Land, a term used by husbandmen to express a sandy soil of a reddish hue, intermixed for the most part with pieces of sand-tinite of the same colour, or somewhat deeper.

It may be noticed that there are several varieties of this soil: one of which is almost entirely made up of sand; another with an admixture of loam with the sand, the whole making a loose loamy earth; and a third, full of fragments of a poor sandy iron ore, and often containing thinning of felsite. See Soil.

In some of the more northern parts of the county of Oxford, there is a rich red sandy loam, upon a red grit-flone rock. In some places this land is of a more sandy quality than in others; and, in particular instances, a deep red loam, or red clay. The lands are moiliy of an excellent quality, both for arable purposes and those of graz; but the sandy forts are better than those of the clayey kinds, especially for the former use. The red sodded tracts in this district are considered as the best and glory of the county, as they are deep, found, friable, and yet capable of tenacity; being well suited to almost every sort of plant which can be trufed to them, in the way of cultivation. Soils of this nature prevail more or less in a vast number of counties throughout the kingdom, even from the more southern ones to those far advanced towards the north.

Red Room, a term signifying the red tinge in ripening barley, and sometimes other sorts of grain.

Red Row, a provincial term, applied to the grains of barley, when in a ripening state, or failed with red. The crop is then laid to be in the red row.

Red Antimony, in Mineralogy, an ore of that mineral, of a cherry-red colour, containing, according to Klaproth, 67.5 antimony, 10.8 oxygen, and 19.7 sulphur.

It occurs most frequently in minute diverging capillary crystals. It melts and evaporates before the blowpipe, yielding a fulvous odour. See Antimony.

Red Arsenic. See Arsenic.

Red Chalk. See Redde, and Ores of Iron.

Red Cobalt, called cobalt crust, and cobalt bloom or ochre, an ore of cobalt, of a peach bloom red colour. See Cobalt.

Red Copper, Ruby copper, an ore of copper, of a cochineal red colour, inclining to a lead-grey. It confines, according to Klaproth, of 91 parts copper and 9 of oxygen. See Copper.

Red Hamalite, Fer olige et concretion de Haüy, an ore of iron, found in kidney-shaped and globular balls. The structure is fibrous, and divergingly radiated, but arranged in concentric curves; the colour is a blue-grey-grey, intermixed with red. By friction, it acquires a high metallic lustre. It yields from 60 to 70 per cent. of pure iron. (See Iron.) An excellent ore of this kind, when procured near Ulverstone, in the north of Lancashire, much valued, as producing an iron of a peculiarly ductile quality, suited for the purposes of the wire-drawers.

Red Lead. See Minium and Lead.

Red Scaly Iron Ore, Fer olige lafiant of Haüy. It consists of scaly particles slightly cohering; it has an unctuous feel, and flains the fingers. It passes into micaceous iron ore.

Red Schorl. See Ores of Titanium.

Red, or Ruby Silver Ore, Argent antimonie fulphure de Haüy. Werner divides this into two sub-species, dark red silver ore, and light red silver ore, distinguished from each other by their colour, and the situations in which they occur. The dark red ore is commonly accompanied by galena, antimonial sulphuret of silver, quartz, calcaceous spar, and pyrites. The colour is between cochineal red and lead-grey. It occurs mafive, disseminated, and crystallized in equatorial six-fided prisms, frequently variegated. The form of the primitive crystal is a rhomboid, whose plain angles are 104° 28' and 75° 32'; the inclination of the faces 95° 28' and 75° 32'. The external lustre is splendent, and in some specimens metallic; internally it is shining, and sometimes semi-metallic and metallic. The fracture is uneven, and in the crystallized varieties imperfectly small conchoidal. See Ores of Silver.

The mafive varieties are opaque; the crystallized, semi-pellucid and pellucid. The colour of the fteak is a cochineal red. This variety yields easily to the knife; before the blowpipe or charcoal it decrepitates, and melts with a slight effervescence, emitting a dense smoke, which colours the charcoal yellow, and leaves a globule of silver. The specific gravity is 5.65 to 5.608.

The light red silver ore is usually accompanied by native arsenic, white cobalt ore, orpiment, and sulphate of barytes. The colour parries from a carmine red to a medium between cochineal red and lead-grey. In most of its characters it agrees nearly with the dark red silver ore; but when fused, it yields an arseufic vapour. Hence some chemists have conjectured that this ore differs from the dark red ore, by the former containing antimony, and the latter arsenic.

According to Klaproth, red silver ore contains nearly 60 of silver, 10.5 sulphur, 29.4 antimony, 3.2 oxygen, 0.7 iron; and 5.9 sulphur.

A variety of red silver ore, probably the light red ore of Werner, analyzed by Prout, gave the composition: 74 sulphuret of silver, 25 sulphuret of arsenic, and 0.6 oxyd of iron.

Red silver ore may be distinguished from cinnabar and red copper ore, by its specific gravity, which is considerably less than the former, and greater than the latter; the specific gravity of red silver ore being 5.6 to 5.8 of cinnabar 7 to 7.5; red copper 3.9.
form of transparent crystals of a pale rose-red colour, and more or less transparent. It was discovered by Klaproth to be a sulphate of cobalt. Its solution affords a pale blue precipitate, with carbonate of potash, which tinges borax a pure blue colour.

**Red Brawn**, in Ichthyology. See **Brawn**.

**Red Eye**, Erythrophalus, the cypinus erythrophalma of Linnaeus, called by some rotheague, or roothing, which, in the German language, signifies the name. It very much resembles the common river breem in shape, but that it is somewhat thicke, the fins are all red, and the whole body of the fish is flained with a very elegant red, but no part of it so much as the iris of the eyes. When the scales are off, the body is of a greenish hue; and it has a yellow spot under the tongue. It very much resembles the river mullet in some particulars, but it is of a more beautiful colour, and its eyes are more red. Its largest size seems a foot in length. It is a well-tailed fish; and spawns in April, under cover of the roots of trees. Ray.

This fish is called red by some English authors; it is also called rutilus latior, rutilio flavitilis, and fapuke. It is very common in many of the rivers of Germany and England, and is in feason all the year, except in spawning time, when the male is subject to a great number of white spots on its head, and is more rough than at any other season. Willughby. See **Cypinus Erythrophalma**.

**Red-Breast**, in Ornithology, a well-known bird, for the characters of which, see Motacilla Rubecula.

The song of this bird is remarkably fine and soft, and continues through the greatest part of the winter, spring, and summer. Many of the autumnal songsters seem to be the young cock red-breasts of that year. Pennant.

Thompson, in his Selcows, Winter, line 245, has admirably described the annual visits of this guest; and the ancient ballad of "The Babes in the Wood," recording the affection of this bird for mankind, is universally known.

**Red Chatterer** of Latham, Red-bird from Surinam of Edwards, and Ampelis carnifex of Gmelin, a bird of red colours, with an ocular band, and the wing and tail-feathers black at their tips. It is found in New Spain, Guiana, and Surinam.

**Red Game**, an English name of a bird, common in the mountainous parts of Yorkshire, and some other of our northern counties. See Gor-cock, Grouse, and Tetrao Lagopus.

**Red-Pole, or Linnet**. See Fringilla and Linnet.

**Red-Pole**, Tellow, or Red-headed Warbler. See Motacilla Petchia.

**Red-Shank**, the name of a water bird, called by authors gallinula erythrobus, and callidrjes; the leolopax cahildris of Linnaeus. It is about the size of the common plover. The back is of a greyish or brownish-green, usually spotted with black; its neck grey, and its throat variegated with black and white; the breast is white, with a few loofe streaks of black; the wing-feathers are variegated with black, brown, and white; the bill is two fingers breadth long, slender, and shaped like the beak of the woodcock; reddish at the base, and blackish lower down; its legs are of a fine beautiful red, and the hinder toe is very short and small. It breeds in the fens and marshes; is found on mott of our shores; conceals itself in winter in the gutters; and is generally found single, or at most in pairs. When disturbed it flies round its nest, making a noise like a lapwing. It lays four eggs, of a whittish colour tinged with olive, and marked with irregular spots of black, chiefly on the thicker end. Ray and Pennant. See Scelopax.

**Red-Star**, the English name of the ruicilla, or motacilla phoenicurus of Linnaeus, a very beautiful bird. The bill and legs of the male are black; the forehead white; the crown of the head, hind part of the neck, and the back, are of a deep blue-grey; the cheeks and throat black; the breast, rump, and sides, are red; the two middle feathers of the tail brown, the others red; the wings brown. In the female, the top of the head and back are of a deep ash colour; the rump and tail of a duller red than those of the male; the chin white; the lower side of the neck cinereous; and the breast of a paler red.

This bird appears among us only in the spring and summer, and is observed to come over nearly at the same time with the nightingale. It is so shy, that it will forsake its nest, formed with moss on the outside; and hair and feathers within, in hollow trees and the holes of buildings, if the eggs are only touched. It has a very fine soft note; and is remarkable for shaking its tail, and moving it horizontally, as a dog does when bawing. Pennant.

**Red-Star, Greater**. See **Lanius Invinctus**. See also Turdus Saxatilis.

**Red-Star, Indian or Bengal**. See **Lanius Emuria**.

**Red-Star, Small American**. See Muscicapa Ruticilla.

**Red-Star, Grey**. See Motacilla Gibraltarcieqis and Erithacus.

**Red-Stone Pigeon.** See Linnet.

**Red-Tail.** See Motacilla Erithacus and Gwianenfis.

**Red-Wing**, the name of a bird of the turdus, or thrush kind, called also in some places the wind thrush, or fraine pipe; and by Linnaeus and others the turdus iliacus, or tils.

It is a little smaller than the common thrush, and is left spotted. Its back, neck, and head, are of the same colour with those of the common thrush; but its sides under the wings, and the feathers which line the wings, are of an orange colour, or dulky red; its belly and breast are whitish, and its throat yellowish, with brown spots: the wings are of a sort of chestnut colour, a little variegated. It feeds on insects, as worms, and the like; and is a bird of patience, coming to us in large flocks about the same time with the fieldfare, and leaving us also when that bird does. When the red-wing appears on the coast in autumn, it is certain the woodcocks are near. It is not well known where they breed, though some have guessed it to be in the mountains of Germany and Bohemia. They have a bitterish taste, and are lefts valued than the fieldfare. With us they have a disagreeable piping note; but in Sweden, during the spring, they sing very finely, perching on the top of some tree among the forest of maples. They nest in hedges, and lay fix bluein-green eggs spotted with black. Ray and Pennant.

**Red Water**, a disea of sheep. It has been suppos'd by farmers to be caused by taking too much watery food, such as turnips, clover, rape, eeal, &c., but it is not peculiar to sheep feeding on turnips or rape, as has been believed by some. Its removal has been attempted by the use of common salt, a tea-spoonful of elixir of vitriol, and the frequent driving the animal about; and it is affirmed, that the disea may be wholly prevented by having recourse to the use of dry food, in the night time, while the sheep are feeding upon those juicy kinds of food. See **Sheep**.

In Suffolk the sheep are sometimes affected with this complaint on their being fired turned into turnips, which is suppos'd to be caused by their eating too large a portion of them in wet feasons. The disea is also believed to originate in the sheep being let out of the fold, when the ground
is covered with hoar frost; and often from feeding in the
oat-erfhes about the beginning of the autumn, when the
young oats are strong. It is thought here to be readily
obviated by allowing a small quantity of hay fo as to coun-
terd the great waterines of the turnip; the quantity of
half a pound or even less in the course of the day is be-
ieved to be quite enough for each sheep in this intention.
It is likewise suspeced, that closer, flubble, and folded
land, are productive of it in wet weather or moist feasons.

Red Weed, in Botany, a name given to a plant common
in the Bermudas, and some other places; and called by our
first travellers to that part of the world, the Summer Island
red weed. Its berry is of a fine red colour, and affords a
trainure little inferior to that of cochineal, and poffefing
all its virtues in medicine: the only misfortune of this, and
some other very fine vegetable: colours, is, that they
fade soon. The juice of the fruit of the opuntia, or
prickly pear, is as fine a dye as can be procured from the
cochineal, but it will not stand; the infect feeding on this,
however, we find affords a colour of the fame nature that
will stand. The fruit of the red weed is in the fame man-ner liable to be eaten by infects as that of the prickly pear;
and it is worthy a trial, whether the colour obtained at
a second hand from the infect will not stand, as well as the
cochineal dye, and whether the infects may not be pro-
gaged in a fufficient abundance to serve the markets in
the fame manner. Phil. Tract. N° 46.

Red Weed is also a provincial term, signifying the
round smooth-headed poppy, a pernicious weed in corn-
fields. See Weeds.

Red Worm, in Natural History, the name of an infect
very destructive to young corn crops. The following de-
scription of this worm has been given by Mr. W. Baker:
after observing, that he has often heard of the havoc
which red worms make in young wheat, barley, and oats;
and in some few writers upon husbandry has read of them,
but never saw them till May 1764; when, to his great mor-
tification, in a few days they destroyed almost totally nine
acres of his wheat, for he did not reap above half a barrel
per acre; and that the ingenious M. de Chateauneuf speaks
of an infect, which is certainly of the fame kind, if it be
not the very infect which he has now under confideration;
and in noticing the Iofs sustained in wheat crops, says, they
found in it many little white worms, which afterwards be-
came of a choiceft colour. They poll themfelves between
the blades, and eat the fleas. They are ufually found be-
tween the leaf joint and the roots; every leaf which
they attacked grew no more, but became yellow and withered.
And the fame misfortune happened to them in the year
1732. The infects appeared about the middle of May,
and made fuch havoc, that the crops were almost destroyed;
Stillingfleet, afo, in the second edition of his Miscel-
naneous Tracts, speaks of an infect, which is probably the
fame as in Suffolk and in some parts of Norfolk, where
the farmers find it their interest to encourage the breed of
rooks, as the only means to free their grounds from the
grub, from which the tree or blind-beetle comes, and which
in its grab flate destroys the roots of corn and grass to fuch
a degree, that he has been a piece of naturall land where you
might turn up the turf with your foot: he adds, that Mr.
Matthews, a very obferving and excellent farmer of War-
grove, in Berkshire, told him, that the rooks one year,
whilst his men were hoeing a turnip field, fat down in a
part of it, where they were not at work, and that the crop
was very fine in that part, whereas in the other part there
were no turnips that year; though M. de Chateauneuf de-
scribes this worm as being firft white, and afterwards be-

coming of a cheftnut colour, he has carefully fought them
at different periods during the falt year, but always found
them of the famé cheftnut colour, never varying in any par-
ticular except that of fize, which they finds to be the cafe at all
feasons in which he has fen them; and he obferves, that the
infect fpoken of by Stillingfleet as a grub, which, he fays,
destroyes corn and grass, induces him to believe that it is the
fame infect (though the report which he relates from Mr.
Matthews feems to contradيط it), becaufe he has obferved that
the red or cheftnut worm never appears voluntarily
upon the surface; but when the earth is turned up,
either with plough or fpade, the rooks or crows are very
bold in their approach to pick them up, a circumftance
which, he owns, has in some degree abated his emnity to
thefe birds; he therefore never destroys or frightens them
off his land whileft he is ploughing it; but when he fows,
when the corn fies, and when it is ripe, he destroys or
banishes them as well as he can, because the mifchief
which they do at thefe times is intolerable; he has also obferved
his lucem to decay in its tops foon after it has been up;
and upon examining the roots they has found the red worm
which had eaten it off; and that, in fact, this infect feeds
to a fpecies which is fowed in fpring and eaten in the fame
year, but by some other fame of the English writers, who have fpoken of an infect which
destroyes the corn in the manner already mentioned, which he
thinks undoubtedly the fame, it is called a grub, by others
the large maggott, and the rook worm, because the rooks eat it.

These worms are about half an inch long, and about one-
tenth of an inch in diameter; they are jointed in their
limbs, and are of a very firm texture; they have many
short legs, two small black specks, which appear to be
their eyes; and two small points springing from their heads,
with which, he believes, they eat the corn, and which in
that work, he apprehends, act like forceps: and all that
he has feen of this fpecies are of a bright cheftnut colour.
For this reafon, he fhou!d conceive it would be more de-
scriptive to call them the cheftnut-worms. When they are
exposed to the aif, by turning up earth which is infettled
with them, they will very soon cover themselves again in
the foil, which they are very capable of doing by the
strength which their make gives them, although they ap-
ppear to be a fluggifh infect, and have not the advantage
of a flimmery upon their limbs, which the common large creep-
ing worm has, which enables that infettive worm to pen-
trate the earth, and get under timber and roots with cafe.
The red worm, immediately endeavouring to cover itself from
the air, is certainly, he thinks, from natural inclination, as it will
foon die when exposed to the air, as will appear by the ex-
periment, N° 10, mentioned below.

It is further related, that these worms destroy wheat, bar-
ley, oats, and lucem, while in an infant flate, in the months
of March, April, and May. Late fown barley and oats
they will destroy as late as June. He has not yet expe-
cienced that they destroy any other crops. The mifchief
done by them is in dry weather. Rain fufficient to pen-
trate the ground makes them defert from destroying the
corn; and he fuppofes every thing elfe which they do at any
time injure. They eat wheat off fublimate the crown of
the roots; barley and oats in the fame place, and also
higher up, upon any part of the item which is below the
surface of the earth. And these worms fseem to abound
more in ground which is lightly tilled, than in fuch as
hath been well tilled; but in lay ground they fteem to be
more numerous than any where elfe: and the fields upon
his farm in which he has found them, are wetter than
other fields where they are not; whether that circumftance
contributes to their increafe, he cannot fay; but the fol-

de-fcribels this worm as being firft white, and afterwards be-

1
lowing experiments prove that they will live longer in water
than they can when exposed to the open air.

Experiments.

No 1. He put ten red worms into a wine glass with com-
mon salt in it. They were all dead in four hours.

No 2. Into a glass with brine in it he put ten red worms.
They were all dead in four hours.

No 3. Into a glass with lime in it, which had been
flaked for a long time, and exposed to the weather, he put
the like number. They were all dead in forty-four hours.

No 4. Into a glass with the above lime, and some water
in it, he put the like number. They were dead in twenty
hours.

No 5. Into a glass with lime newly flaked, and when
cold, he put the like number. They were dead in fourteen
hours.

No 6. Into lime water, made with cold water, he put the
like number. They were dead in ten hours.

No 7. Into a glass with foot in it, he put the like number.
They were dead in four hours.

No 8. Into foot and water he put the like number.
They were dead in four hours.

No 9. Into pure water he put the like number. They
were dead in fifty-two hours.

No 10. Into a glass, without anything in it, he put
the like number. They were dead in thirty-two hours.

It is flat that by these experiments it is seen that all the
articles used will kill this insect in a short time, particularly
the falt and foot. He thought it necessary to consider dif-
ferent articles, the better to suit different parts of the
kingdom.

Where lime can be conveniently had, and that it is used
as a manure, he is apt to believe, from the experiments,
that no injury can be sustained from these worms; but he
is afraid a small quantity will not effectually destroy them
besides, if he should fear, if it were not put on before the fow-
ing of the corn, that it might finge the blades of the corn;
for, from these experiments, it appears that lime newly
flaked is more suddenly destructive to them than old lime,
and therefore it is to be preferred.

Where lime is used for no other purpose than to destroy
this worm, he should conceive, that about eight barrels,
regularly fown by hand on an acre of ground, might be
sufficient: it must be firt flaked and cold before a man
can possibly cast it upon the ground with his hand, lime
being a very strong caufic; and even when it is cold the
man should have a thick glove upon his hand.

Where falt may be used to destroy this worm, it must al-
ways be fown upon the ground before the intended crop;
for although corn will vegetate, and receive benefit from
falt as a manure, when it is used antecedent to the fowing
of the corn, yet if it be added after the corn is growing
it will certainly destroy it: therefore it should never be
used for this purpose, but before the corn is fown, or at least
before it vegetates.

He conceives that where falt is used for this purpose
only, about four hundred and a half to an acre will an-
swer the purpose, which is a little more than one ounce
to every square yard.

It is seen by the experiments, that foot kills this worm as
soon as falt; and as in most places it is to be had at a
much less price than falt, he thinks there can be no doubt
about preferring it; besides which, it may be safely used
after the corn is up.

He had some small parcels of barley under experiments,
which these worms began to destroy; and in order to con-
vey the foot as soon as possible to the roots of the plants,
he mixed a little of it in water, and poured it on the plants
with a garden watering-pot: the confequence was that he
did not lose one plant afterwards.

It will hardly be imagined that he means that the fame
method is to be pursued upon a whole farm; no; the
method he would recommend to the practice of the farmer
is this; to spread, or cast by hand, as he fows his corn,
about fix or eight barrels of foot on an acre, and let him
be careful to choose a calm day for the work, otherwife
the wind will carry away a great part of it; and as what
remains cannot be regularly difpofed, let him be careful to do
it early enough in the spring, that the rain may waft in the
foot and convey it to the roots of the plants before the worm
begins its milchief; if he does this, he is perfuaded his crop
will be preferved.

It is found by the experiments, that these worms will live
longer in water, by twenty hours, than when exposed to
the open air; but at length, that is in fifty-two hours,
they die in the water; perhaps this might be from the
effect of drowning; but if so, he might have expected they
would have been totally destroyed in his two fields in
the winter of 1763 and 1764, by the immoderate rains
which fell at that season for a long continuance, which
often flooded the lands. But they survived this winter,
as appeared by the great loss he afterwards suffered by
their destroying his wheat; and therefore, whether water
be an enemy to them or not, it seems not easy to deter-
mine; but if those which died in the glasses of water were
really drowned, he thinks we may conclude that water is
necessary to their existence in the earth, and probably aids
them in getting their food from it; and what seems to con-
firm this notion is, that when the land is wet, they do
not touch the corn, but as soon as ever the land is dry, they
begin their milchief. However, this speculation must
submit to the consideration of persons more capable of
diffculting it than he is.

It is seen by experiment No 10, that they cannot live
in the open air which seems to prove, that, where they
abound in land, the oftener it is ploughed, particularly in
the summer, when they cannot penetrate the ground so
easily as when it is moist, they must be, by fuch plough-
ing, greatly diminished; besides which, the frequent plough-
ing gives the crows more opportunities of picking them up,
in which, as he has before faid, they are very watchful.

Frequent ploughing has been recommended by fome
writers as the only means of destroying this worm; and
they have recommended the ploughs being ftruck with nails,
urging, that by thofe nails the worms are cut to pieces;
others have recommended walnut leaves being soaked in
water, to sprinkle the land, and fleeping feed corn in va-
rious liquors, as infallible remedies; but fuch methods as thefes
are founded upon mistaken principles; they only mislead
the farmer, and must disappoint him.

Worledge recommends a frong ley made of fixed farts,
but that would be impracticable. Mortimer recommends
tea-water, which he believes would answer very well. He
faies, he used foot once with Succefs, but that it did not
fuccefs with him afterwards. Mr. Baker is perfuaded he
did not use the foot early enough to have it wafted into
the ground by rain, or perhaps he used too small a quan-
tity. He concludes by obferving, that he would not be
thought to arrogate any merit to himself, on account of
what he has here offered on this Subjeft, fince it appears
that other perfons have used the articles which he has
recommended, againft this common enemy; but many per-
fons have been disappointed in their expectations from these
remedies,
RED

remedies, which must have arisen, he thinks, from their either having used too small a quantity, or not having observed the necessary precautions; if those which he has recommended shall be put in practice and found to answer, he shall think himself amply rewarded.

This worm undoubtedly does great injury to grain crops in many places, in particular soils and parts of land; but a great number of additional facts and experiments are wanting to fully prove its nature, and the ways in which its destructive effects on such crops are produced, as well as the best, most ready, convenient, and effectual ways in which it can be destroyed. See Wire-worm.

**RED Deer.** *Cervus elaphus,* before the invention of printing, were used for adornment. In the MS. at Paris of the Latin and French poems of Guillaume Machaut le Petit, chiefly motets for a single voice, some are written in black and red notes, with this instruction to the fingers; "ni-græ senæ perfeqtæ, et rubra imperfectæ;" an admonition worth remembering by those who wish to decipher music of the fourteenth and fifteenth centuries, in which red notes frequently occur. It was an easy expedient of diminution till the invention of the press, when the use of different colored inks on the same page occasioned the trouble and expense of double printing. See Machaut.

In the Papyrus collection at Cambridge, there are examples of the use of red notes for diminution in fragments of music by Joseph Gwinneth and Robert Davie, who flourished in the time of Edward IV. Morley has given some examples of the use of red notes in his annotations. See Machaut.

**RED Bank.** In Geography, a fort of the United States, on the S.E. side of the Delaware river, in the town of Woodbury, Gloucester county, New Jersey; seven miles S. of Philadelphia.

**RED Bay,** a bay on the N. coast of Spitzbergen. N. lat. 79° 44'. E. long. 10° 42'.—Alfo, a bay on the S.E. side of Labrador. N. lat. 51° 50'. W. long. 60° 10'.—Alfo, a bay on the N. part of Buffaloe's bay, on the S. coast of Massachusetts, in America.

**RED Crab Island,** a small island in the E. part of the Indian sea, near the coast of Arracan. N. lat. 21° 30'. E. long. 91° 50'.

**RED Deer Lake,** a lake of North America. N. lat. 55° 10'. W. long. 112°.

**RED Flagg Bay,** a bay on the N. coast of Scotland, on the N. coast of the county of Banff; three miles E. of Cullen. N. lat. 57° 39'. W. long. 2° 38'.

**RED Head,** a cape of Scotland, on the E. coast of the county of Angus; six miles S. of Montrose. N. lat. 56° 33'. W. long. 2° 26'.—Alfo, the N. point of the island of Eda. N. lat. 59° 6'. W. long. 2° 40'.

**RED Hills,** rocks in the German sea, near the coast of Northumberland. N. lat. 55° 26'. W. long. 1° 17'.

**RED Hook,** a town of America, in the township of Rhynebeck, and Dutchess county, New York, on the E. bank of Hudson's river; 21 miles S. of Hudson.

**RED Horse, Vale of,** a district of England, in the county of Warwick, which owes its name to a horse cut in a hill, the foil of which is reddish.

**RED Island,** an island near the E. coast of Labrador. N. lat. 43° 55'. W. long. 55° 50'.—Alfo, an island near the W. coast of Newfoundland. N. lat. 48° 35'. W. long. 59° 10'.

**RED Lake,** a comparatively small lake of North America, at the head of a branch of the Bourbon river, sometimes called "Red river;" its form is nearly round, and its extent is about 60 miles in circumference. It has on one side an island, close by which a river enters. It lies almost S.E. both from lake Winnipeag, and from the lake of the Woods. N. lat. 51° 5'. W. long. 94° 10'.—Alfo, a lake of North America, in N. lat. 47° 40'. W. long. 95° 15'.

**RED Lick,** a salt spring of the state of Kentucky; 32 miles E. of Stanford.

**RED Point,** a cape on the E. coast of New Holland. N. lat. 34° 29'. W. long. 28° 45'.

**RED River,** a river of Louisiana, which rises in about N. lat. 35°, and W. long. 96°, and runs into the Mississippi. N. lat. 37° 15'. W. long. 91° 48'.—Alfo, a river of Upper Canada, which runs into lake Superior. N. lat. 47° 51'. W. long. 85° 48'.—Alfo, a river of Tennessee, which runs into Cumberland river, about two miles N.W. of Clarksville. N. lat. 36° 18'. W. long. 87° 46'.—Alfo, a river of Kentucky, which runs into Kentucky river, about nine miles above Boonsborough, N. lat. 37° 45'. W. long. 84° 18'. It is 60 yards wide at the mouth.—Alfo, a river of North America, which rises from Red lake, in N. lat. 47° 45', and runs into Winnipeg lake.—Alfo, a river of Canada, which runs into the Otawa; 60 miles W. of Montreal. See also NATCHEZ-CHOOES.

**RED Sea,** called by the ancients the "Arabian gulf," forms the grand natural division between Asia and Africa, and extends about 21' or 1470 British miles from the frigates of Babelmandeb to Suez; it terminates in two branches, the western being extensive, and the eastern ascending a little beyond the parallel of mount Sinai.

This sea is called, in the Old Testament, the sea of Suph or Zuph, the sea of weeds, on account of the great quantity of algae and fuci, and perhaps the madreporites and coraline substances, anciently supposed to be of vegetable origin, found at its bottom, and near the shores. In scripture language it is also denominated "the tongue of the Egyptian fea;" in the Greek and Latin geography, it was called the gulf of Heroopolis; and by the Arabian geographers, the western arm of the sea of Kolzum, (al Kolzum, with the article,) which seems to have some affinity with "Clymen," another name by which this gulf was formerly known; Kolzum in Arabic, and Clymena in Greek, signifying defraction, in reference, as it is supposed, to the defraction of Pharaoh's hoi. Don John de Castro, vice-roy of the Indies for the king of Portugal, conjectures that it was called the Red sea from the great quantity of coral that is found in it. Pliny says that it obtained this name, in Greek "Erythrius," from a king called Erythros, who reigned in Arabia, and whose tomb was seen in the islad Tyrie or Agyria. Several learned men believe, that this king Erythros is no other than Esau, or Edom; Edom, in Hebrew, signifying red or reddish, as Erythros does in Greek. But Calmet is of opinion, that Edom never dwelt, either on the shore of the Red sea, or the Persian gulf, which has been sometimes also called the Red sea. His habitation was eall of the land of Canaan, towards Bozra; and he inclines to believe, that the name of the Red sea was not given to this gulf till after the Idumeans, defended from Edom, had spread themselves from east to west as far as the Red sea. At that time it might receive the name of the sea of Edom, which the Greeks rendered by the Red sea, or "thalassa erythriae."

The famous miracle of the poffage of the Red sea by 600,000 Israels, besides old men, women, and children, recorded in the sacred writings, is well known. Those who have been devious of explaining this paffage, without
out admitting the miraculous part of the history, have had recourse to a variety of conjectures; both as to the place and the manner in which this passage was effected. As to the place of the passage, there has been a difference of opinion even among those who have not hesitated to acknowledge that it was miraculous. Till of late years it has been generally believed, that the passage of the Israelites was at Baideah, or Bedea, which, according to Niebuhr, is about six German miles from Suez, and where the sea, says Bruce, is something less than four leagues broad, by 50 feet deep. In support of this hypothesis, Dr. Shaw has traced the march of the Israelites to their third encampment before Pihahiroth. Whilst they were removing from the edge of the wilderness of Etham towards this station, they had left the open country and were marching through a narrow pass, between the mountains of Gevoubee and Attackah. In those circumstances the Egyptians might well imagine, that they could have no possible way of escape, as the mountains of Gevoubee would obstruct their progress towards the south, and those of Attackah would impede their advancing towards the land of the Philistines; the Red sea lay before them to the east; whilst Pharaoh cloosed up the valley behind them, with his chariots and horsemen. This valley terminates at the sea, in a small bay, made by the eastern extremities of the mountains above-mentioned; and is called "Thiah Beni Israel," i.e. the road of the Israelites, from a tradition still existing among the Arabs of their having passed through it; and it is also called "Baidah," from the new and unheard-of miracle that was wrought near it, by dividing the Red sea, and destroying in it, Pharaoh, his chariots and his horsemen. The encampment of the Israelites, according to Dr. Shaw, was at this bay, before Pihahiroth, betwixt Migdol and the sea, over against Baal-tzephon, Exod. xiv. 2. Baaltzephon, as this learned geographer fugitives, might have relation to the northern situation of the place itself, or to some watch-tower, or idol-temple, that was erected upon it; or it may be taken for the extremity of the mountains of Suez, or Attackah, the most conspicuous of these defects, as it overlooks a great part of the Lower Thesba, as well as the wilderness that reaches towards, or rather which makes part of, the land of the Philistines. Migdol might lie to the south, as Baal-tzephon did to the north of Pihahiroth. The marches of the Israelites, from the edge of the wilderness, being towards the sea, i.e. towards the S.E., their encampment betwixt Migdol and the sea, or before Migdol, could not well have any other situation. Pihahiroth, or the mouth of Hhiroth, or a narrow gullet or defile, may denote the mouth, or the most advanced part of this valley towards the E., or towards the Red sea. But as the Israelites were delivered at this place from their captivity and fear of the Egyptians (Exod. xiv. 13.) we may suppose that Hhiroth denotes the place where they gained their liberty, hereby and Hhiroth being words of the like import in the Chaldee. It may be further urged in favour of this explication, and also of the tradition still preferred, of the Israelites having passed through this valley, that the eastern extremity of the mountain, supposed to be Baal-tzephon, is called, even to this day, by the inhabitants of these deferts, "Jibbel Attakah," or the mountain of deliverance; which appellation, together with those of Baideah and Tiah Beni Israel, could never have been given or imposed upon those inhabitants at first, or preferred by them afterwards, without some faithful tradition, that such places had been once the actual scene of these remarkable transactions. The sea likewise of Kolzum, i.e. destruction, as the correspondent part of the Red sea is called in the Arabian geography, is a further confirmation of this tradition. Moreover, the Jethyphaghi, who lived in this very neighbourhood, are reported by Diodorus Siculus (I. iii.) to have preferred the like traditional account from their forfathers, of this miraculous division of the Red sea. There are likewise other circumstances that tend to prove, that the Israelites took their departure from this valley, in their passage through the Red sea; for an account of which we refer to Shaw's Travels, ch. v.

This hypothesis, however, says Geddes, (Crit. Remarks on Exod. xiv.) has been fairly given up by our best modern critics; and the "Sinus Hegoopolitanus," or gulf of Suez, pitched upon as the scene of action. The idea was first suggested by Le Clerc, and since adopted and defended by Michaelis, Niebuhr, and almost all the German commentators. But Mr. Bryant still contends for Bedea (Baideah), and calls the arguments of Niebuhr "prejudice and misconception." Dr. Geddes, whose sentiments concerning Moses and his whole history are singular, denies that there was any thing miraculous in the event; and strenuously maintains, that Suez or its vicinity was the place of passage; for here, he says, at this day, there is shallow fordable at low water, and which might, in former times, have been frequently dry. We all know what changes happen in the bed of seas as well as that of rivers, especially where that bed is sand, which is the case with that of the gulf of Suez. The occurrence is thus described by Dr. Geddes. When Moses saw that the Egyptians had found out that the Israelites meant not to return, and were about to pursue him with a force which he could not resist, he wisely took the only course that was most likely to afford him an escape. Acquainted, as he must have been, during his long stay in Midian, with the nature of the Red sea, and its ebbs and flows, he deemed it better to take his chance of passing over some shallow which he knew to be fordable at low water, than to expose himself to be overtaken in a defert, where no stratagem could save him. If he got the start of the Egyptians but for a single day, he would have time to watch the tide, and begin his march as soon as the passage was fordable; and in the space of a few hours might be safe on the other side. The width of the sea at Suez is at present, according to Niebuhr, 757 double paces, or 3450 feet. It is common for the Arabs to pass on foot over this passage, although not always without danger, as the sea sometimes flows back unexpectedly. At Suez, according to Niebuhr, it is low water, at the full of the moon, at half past six; but as the passage of the Israelites must have happened some days after the full of the moon, the ebb and flow must have been considerably later, and the former must have occurred in the night-time, during which the Israelites are said to have passed. Michaelis was of opinion, that, as a strong wind is said to have accompanied this event, it might have caused a double ebb, as it sometimes does on the coast of Holland and North Germany; but Niebuhr thinks that no such thing is likely to happen in the Red sea. Be this as it will, the wind might certainly have prolonged the ebb; and, if it happened at the time of the passage, might well be considered as a providential intercession, and readily conformed into a miracle. Jophthus, in recording this transaction, puts a formal speech into the mouth of Moses to his terrified and discontented people, and a prayer to God before he strikes the sea with his rod; yet he tells us that all this he has related as he found it in the sacred books. But he seems not sure, whether to consider it as a miracle or a natural effect. "Let no one," says he, "wonder at this account of a way of safety being opened to those old-world innocent folks, even through the sea, whether by the will of God or naturally; since, of later days, the Pamphylian sea opened a way
way for Alexander's army, when God through him had decreed to overturn the Persian empire." (Antiq. i. ii. c. 16. n. 5.) For this he appeals to all Alexander's historians; and, indeed, both Appian and Arrian, who relate the event, seem to have considered it as a sort of divine interposition; but honost Strabo tells us, that Alexander only took the advantage of low water; and, trusting to his good fortune, passed through the Suez with his army; but not on dry land; for the water came up to the navel. (Strab. l. xiv.) The fame was the case with Scipio's soldiers, who surprized New Carthage by taking the advantage of an ebb; although they waited sometimes up to the knees, at other times up to the navel, in water. (Liv. i. xix.) Here, says Geddes, the fame two natural cafes, the tide and a strong wind, concurred to make a passage through the water, as occurred at the passage of the Red sea; and in both cafes they were converted into a miracle. Josephus concludes his narrative with these words: "Of such things, let every one think as he pleases," and the author now cited adopts his language. It has been said, and thus the priests of Memphis explained the history (see Esneh. Prep. i. iv. c. 17.), that Moses taking advantage of the time of the ebb, led the Hebrews over in safety; but the Egyptians, not knowing the nature of the sea, and easily entering it just before the return of the tide, were all swallowed up and drowned.

In opposition to all conjectures for explaining this history, without having recourse to miracle, we shall content ourselves with appealing to the history itself, Exod. xiv. 16, 17, &c. from which it appears that the Hebrews traversed the sea from shore to shore, on a large space of dry ground, which was left by the retiring waters; and that they were driven back to overwhelm the pursuing host of Pharaoh. See also Isaiah, xi. 11, &c. Habakkuk, iii. 15. Wisdom of Sol. xix. 7, 8. x. 17, 18.

It is thought, says Calmet, after Esnehbius, that the place where the Hebrews passed the Red sea, is two or three leagues below its northern point, at the place called Kolfum, or Clylma. Niebuhr informs us that, every where on the coast of Arabia, we meet with indications, that the waters are withdrawn; e. g. Mus, which ancient authors mention as a port of Arabia, is now at many leagues distance from the sea, near Loheta, and Gidda, we see great hills filled with the same kind of shells and corals, as are now found living in the sea, near Suez, are petrifications of all these things. From these and similar circumstances it appears, that some thousand years ago this Arabian gulf was much larger, and extended much farther north, especially that arm of it near Suez, for the shore of this extremity of the gulf is very low. The breadth of the arm of the sea at Suez, he adds, is about 3400 or 3500 feet (in its present state). Although it would much shorten the distance of their way, no caravan now crosses this arm, nor could the Israelites have crossed it, without a miracle. The attempt must have been much more difficult to the Israelites, some thousand years ago, the gulf being then probably larger, deeper, and longer toward the north, at the lowest time of the tide. Niebuhr crossed, when returning from mount Sinai, that arm of the sea, over to Kolroum, upon his camel; and the Arabs, who accompanied him, were only immersed to their thighs in water. The banks of the Red sea are pure sand from Suez to Girondel; but lower to the south are banks of coral. If the Israelites had crossed the sea upon such banks, they must have been greatly incommoded by them.

The Red sea, notwithstanding the difficulty and danger, and also the tediousness of its navigation, was, for many ages before the discovery of the passage by the Cape of Good Hope, the channel of communication between Egypt and other countries, bordering on the Mediterranean, and India. Accordingly, Dr. Robertson observes, in his "Historical Disquisition concerning Ancient India," that navigation made its first efforts in the Mediterranean and the Arabian gulf, and that in them the first active operations of commerce were carried on. Nor are the accounts of the earliest historians in this respect at all improbable, if we consider the position and form of these two great inland seas. They lay open the continents of Europe, Asia, and Africa, and spreading to a great extent along the coasts of the most fertile and most early civilized countries in each, seem to have been defined by nature to facilitate their communication with one another. We find, accordingly, that the first voyages of the Egyptians and Phoenicians, the most ancient navigators mentioned in history, were made in the Mediterranean, and, moreover, by acquiring early possessions of ports on the Arabian gulf, they extended the sphere of their commerce, and are represented as the first people of the west who opened a communication by sea with India. Such, in the course of his reign (if we may give credit to some historians), was able to fit out a fleet of 400 ships in the Arabian gulf, which conquered all the countries stretching along the Erythrean sea to India. The Phoenicians, who, by their situation on the Mediterranean, and the imperfect state of navigation, could not attempt to open a direct communication with India by sea, were promptly by the enterprising spirit of commerce to wreak from the Idumeans some commodious harbours towards the bottom of the Arabian gulf. From these they held a regular intercourse with India on the one hand, and, with the eastern and southern coasts of Africa on the other. The distance, however, from the Arabian gulf to Tyre was so considerable, that it became necessary for them to take possession of Rhinocolura, the nearest port in the Mediterranean to the Arabian gulf. Thither all the commodities brought from India were conveyed over land by a route much shorter, and more practicable, than that by which the productions of the East were carried at a subsequent period from the opposite shore of the Arabian gulf to the Nile. At Rhinocolura they were redelivered and transported by an easy navigation to Tyre, and distributed through the world. For an account of the trade which the Jews carried on by the Red sea, we refer to the articles Euphrates and Tyre. For the manner in which the Egyptians carried on their trade with India by means of this gulf, see ALEXANDRIA and BERENICE.

All the commercial transactions of the ancients with the East were confined to the ports on the Malabar coast, or at the farthest extended to the island of Ceylon. To these staples, the natives of all the different regions in the eastern parts of Asia brought the commodities which were the growth of their several countries, or the product of their ingenuity, in their own vessels, and with them the ships from Tyre and from Egypt completed their investments. While the operations of their Indian trade were carried on within a sphere so circumscribed, the conveyance of a cargo by the Arabian gulf, notwithstanding the expense of land-carriage, either from Elath to Rhinocolura, or across the desert to the Nile, was so safe and commodious, that the merchants of Tyre and Alexandria had little reason to be solicitous for the discovery of any other. During the period in which this mode of carrying on commerce fulfilled, the price of goods imported from India into Europe was very much enhanced by the various operations to which the conveyance of them was subject. In Ceylon, or the ports on the Malabar coast to which they were brought from the various countries of Asia by the natives, they were put
RED

put on board the ships which arrived from the Arabian gulf. At Berenice they were landed, and carried by camels 258 miles to the banks of the Nile. There they were again embarked, and conveyed down the river to Alexandria, whence they were dispatched to different markets. But, after the passage to India by the Cape of Good Hope was discovered by Vasco de Gama, at the close of the fifteenth century, its various commodities were purchased at first hand in the countries of which they were the growth or manufacture; and as the carriage of mercantile goods by water is much less expensive than by any other mode of conveyance, the Portuguese, as soon as they could import the productions of India in sufficient quantities to supply the demands of Europe, were able to afford them at such a reduced price, that the competition of the Genoese and the Venetians, who had been actively engaged in this commerce, ceased almost entirely; and the full stream of commerce took its natural direction towards the cheapest market. The consequence was, that early in the sixteenth century, the subjects of the Portuguese monarchs became possesseors of a monopoly of the trade with India, founded upon the only equitable title, that of furnishing its productions in greater abundance, and at a more moderate price. From the era of the discovery now mentioned, the Arabian gulf or Red sea lost its importance as a channel of communication between the western and eastern parts of the globe; and from this time both its navigation, and the commerce connected with it, have been partial and restricted. An account of its principal ports will be found under their respective articles.

REDA, a town of Turkish Armenia, in the government of Erzerum; 36 miles N. of Ipira.

REDAH, or REDANT. See REDENS.

REDARIDES, in Geography, a town of France, in the department of the Mouns of the Rhone; 16 miles S.S.E. of Orangi.

RED BOOK of the Exchequer (liber rubus faccarit) is an ancient record, in which are registered the names of those that held lands per baroniam in king Henry II.'s time. It is a manuscript volume of several miscellaneous treaties, in the keeping of the king's remembrancer, in his office in the exchequer; and hath some things (as the number of the hides of land in many of our counties, &c.) relating to the times before the Conquest. There is likewise an exact collection of the fines of various men under king Henry I., Richard II., and king John; and the ceremonies used at the coronation of queen Eleanor, wife to king Henry III. &c.

REDDAT. Precipe quod reddat. See Precipe.

REDDENDIS CHARTIS. See Chartis.

REDDENDUM, in Law, a clause in a lease, &c. by which a rent is referred to the lefsee; which anciently consisted of corn, flet, fish, and other victuals. 2 Rep. 71.

REDDIDIT 8s., where a man procures bail for himself to an action in any court at law; if the party bailed at any time before the return of the seconfe feire facias against the bail, renders himself in discharge of his bail, they are thereby discharged. 2 Litt. 430. See Bail.

REDDITARIUM, an ancient law term for a territory, roll, or rental, in which the rents and services of a manor are let down.

REDDITION, REDITION, a surrendering or returing. In Law, it also denotes a judicial acknowledgment that a thing in quession belongs to the demandant, and not to the persons so surrendering.

REDDITUS ASSISIUS, a fet or flanding rent. See Assisius.

REDDELE, Red Ochre, or Red Chalk, in Mineralogy, the red oxvd of iron intermixed with earthy matter. It is Vol. XXIX.

used for crayons, either in its natural state, or pounded and washed, and afterwards mixed with gum, and cut into moulds. The colour of reddele varies from a blood-red to a brown-red; its fracture is earthy; it is soft, friable, and flakes the fingers. See Orris of Iron.

This is the common English name for the substance called in Latin rubiaca, and used in painting, and for marking sheep, &c. There are two kinds of it, a harder and a softer.

The first, or harder kind, is but little in use, except among the turners in wood, as it does not mark so easily, requiring to be first wetted, and then pressed hard upon the substance to be marked. This is dug in Lincolnshire, Hampshire, and Suffolk; and is a hard and dry earth, of a somewhat pale red, like the common pale red bricks, and is of a very regular and close texture, and always composed of a number of thin laminas, lying closely and evenly on one another. It is of a rough uneven surface, adheres firmly to the tongue, is not easily broken between the fingers, and flakes the hands a little; it is of a very adhesive quality, and melts readily in the mouth. It is very readily fusible in water, mouldering to powder, soon after being thrown into it; and makes no effervescence with acids.

The second, or softer kind, is very common, and put to a number of different uses. It makes simply a very good pale red for the painters, and is very serviceable to them in their mixed colours. It is in constant use in many parts of the kingdom for the marking of sheep; and when washed and separated from its sandy particles, is, by some of our modern druggists, sold under the name of bole armeniac.

It is found in many parts of the world: the best in England is that from several parts of Derbyshire, from whence the colour-flours and druggists of London are supplied; many of the latter thinking this a shorter method than the common one of our bole armeniac makers, of preparing it from a mixture of tobacco-pipe clay, and the red ochre called Spanish brown.

This lof, or common reddele, is a loose ponderous earth, of a lax texture, and very friable; and of a pale, but tolerably bright red, of a somewhat smooth and glossy surface, soft to the touch, adhering firmly to the tongue, easily broken between the fingers, and flakes the hands. It is of a rough auriferous quality, very readily breaks, and falls to powder in water, and makes no effervescence with aqua fortis. Hill.

Some call reddele, lapis hematitie; but the real hematities is another thing.

REDEEMABLES, in Law, are lands, funds, &c. sold with a reservation of the equity of redemption.

Crown lands are redeemable for ever; others only for a certain time.

RE-DELIVERY, an yielding or delivery back of a thing; if a person has committed a robbery, and stolen the goods of another, he cannot afterwards purge the offence by any re-delivery. Co. Litt. 69. H. P. C. 72.

RE-DEMISE. See Demise.

REDEMPTION, REDEMPTIO, a faculty or right of re-entering upon lands, &c. that have been sold, and applagued; upon reimbursing the purchase-money, with legal costs.

Bargains in which the faculty, or, as some call it, the equity of redemption, is reserved, are only a kind of pignora

tive contracts.

A certain time is limited, within which the faculty of redemption shall be exercised; and beyond which it shall not extend.

REDEMPTION, in Theology, denotes the recovery of man- 4 E
kind from sin and death, by the obedience and sacrifice of Christ, who on this account is called the Redeemer of the world. See Covenant.

Redemption, Redemptions, in our old Law Writers, denote grievous misfortunes imposed by way of commutation for the head or life of the delinquent.

Redemption of the National Debt. See Fund.

REDEN, or Reden, in Geography, a town of Prussia, in the territory of Culm; 20 miles N.E. of Culm.

REDENS, Redans, or Redant, in Fortification, a kind of work indented in form of the teeth of a saw, with salient and re-entering angles; to the end that one part may flank or defend another.

It is also called saw-work, and indented work. The faces in this flank one another.

Redens are frequently used in the fortifying of walls, where it is not necessary to be at the expense of building battlements; as when they stand on the side of a river, a marsh, the sea, &c. But the fault of such fortification is, that the besiegers from one battery may ruin both the sides of the tenaille or front of a place, and make an assault without fear of being engulfed, since the defences are mined.

The parapet of the corridor also is frequently redented, or carried on by way of redans.

REDES, in Geography, a river of South America, which runs into the gulf of Darien, N. lat. 7° 37'. W. long. 76° 12'.

REDHIBITION, Redhibito, in the Civil Law, an action allowed a buyer, by which to annul the sale of some moveable, and obliges the buyer to take it back again, upon the buyer's finding it damaged, or that there was some personal cheat, &c.

The redhibition, or redhibitory action, has a place in several cafes, in the body of the civil law. If a horse was sold that had the glands, were broken-winded, or foundered, it was a redhibitory cafe; and the seller might be obliged to take him again within nine days.

REDI, Francis, in Biography, an Italian physitian, was defended from a noble family, and born at Arezzo, in Tuscany, in the year 1626. He commenced his studies at Florence, and then removed to Pisa, for the prosecution of his philosophical and medical pursuits, where he received the degree of doctor in both these sciences. He had acquired great reputation both in science and literature, and was induced to settle at Florence, where he at length gained the favour of the court, and was appointed first physician to Ferdinand II. duke of Tuscany, and subsequently to Cosmo IIII.. These appointments and his constant professional employment did not, however, prevent him from cultivating his favourite study of the belles lettres. He devoted much of his time to the language of his country, and contributed not a little to the perfection of the dictionary of the academy of La Cruca, of which, and of several other learned bodies, he was a member. Totally free from preconception, and attached to every cultivator of learning and science, he was always ready to give his assistance to them in every way he could, and was universally esteemed and beloved. He displayed both in his practice, and in the prosecution of his inquiries in natural history, a singular acuteness of observation, and a complete incredibility as to the marvellous, which was so prevalent in his time, and he cautioned his friends and pupils against the popular errors in this respect. Although he was afflicted with epileptic fits in his latter years, yet he appears neither to have abandoned his studies, nor his professional business, until his death, which took place in 1697, in his 71st year.

Redi was the author of several Italian poems, which are held in much estimation. His other works were all written in Italian, and his style was deemed to pure and elegant, that the authors of the dictionary of La Cruca have often cited it as a standard. Most of his writings on natural history have been translated into Latin; especially his "Experiments circa Generationem Infectorum, cum Figuris Aenear," his "Observationes de Vipers," his "Experiments circa diversas Res naturales, specimini illis quae ex Indius adferunt," and his "Observationes de Animalibus viventerbus, que intra Animalia viventera reperietur." He also published a letter on the Use of Spectacles, and an Essay on Stupics. Eloy Diet. Hist. de la Med.

Redi, in the notes to his "Baco in Toscana," a dithyrambic poem, published in 1685, has given many curious etymologies and explanations of the musical terms used by the Italians in early times.

REDIGOODEM, in Geography, a town of Hindostan, in the ciree of Ellore; 25 miles W. of Ellore.

REDIMICULUM, among the Romans, a girdle, which going about the neck, divided on the breast, and passing down each side, went round, and kept the robe tight to the body.

REDINKA, in Geography, a town of Portugal, in the province of Beira; 14 miles S. of Coimbra.

REDINTEGRATED MEDALS. See Medal.

REDINTEGRATION, Redintegration, in the Civil Law, the act of restoring a person to the enjoyment of a thing, of which he had been illegally disfrappled.

In France, where a person is defpoiled of his property, he claims it again by redintegration, or action of restitution. But the redintegration must be demanded within a year and a day, otherwise it is precluded.

Redintegration, in Chemistry, the restoring of any mixed body, or matter, whose form has been destroyed by calcination, corrosion, sublimation, or the like, to its former nature and constitution.

The redintegration of mercury is properly called vivification. Mr. Boyle has an express treatise on the redintegration of saltpetre; where he shews, that after reducing it by fusion into fixed nitre, which is next of kin to salt of tar, in all its properties, he could perfectly redintegrate it, by pouring a sufficient quantity of spirit of nitre on it; i.e. he could re-produce true crystals of the usual form and virtue of salt-petre.

It is a strong objection against the chemical principles, that we cannot redintegrate the body they were procured from, by re-mixing them. This seems to argue, that the body did not properly consist of such elements, or that they were not originally contained in it, but were rather produced by the fire.

REDIPATAM, in Geography, a town of Hindostan, in Marowar; 18 miles N. of Ramnagaropur.

REDIRE ad Passum, in Law, is applied to a person, whose outlawry is revered, and who is restored to the king's peace.

REDISSEISIN, a diffision made by him who once before was found and adjudged to have difeised the fame man of his lands or tenements; for which there lies a special writ, called a writ of restitution. See Assize of Novel Disfasson, Disseisin, and Post-Disseisin.

REDMANS, or Redmans, in Doomday and other ancient books, are properly the name with rod, or rad-knights; viz. men who, by the tenure or custom of their lands, were to ride with, or for, the lord of the manor, about his businesses.

REDNITZ, in Geography, a river of Germany, formed by the union of the Upper and Unter Relat, about 5 miles S. of Roth, in Franconia. After receiving in its course several
several streams, it discharges itself into the Maine, a little below Bamberg.

REDOLESCO, a town of Italy, in the department of the Mincio; 14 miles W.S.W. of Mantua.

REDON, a town of France, and principal place of a district, in the department of the Ille and Vilaine; 32 miles S.S.W. of Rennes. The place contains 3783, and the canton 11,620 inhabitants, on a territory of 1872 square kilometres, in 5 communes. N. lat. 47° 39'. W. long. 2°.

REDONDA, an island in the Welf Indies, about 10 miles in circumference, without ports, rivers, or towns. N. lat. 16° 55'. W. long. 62° 20'.

REDONDela, or Redondillo, a town of Spain, in the province of Galicia, near the west coast, defended by a strong castle; 32 miles W.S.W. of Orenna.

REDONDO, a rock, about three miles in circumference, between the islands of Montferrat and Nevis, in the Welf Indies. N. lat. 17° 6'. W. long. 61° 35'.

REDONDO NUEVO, a town of Benguela. S. lat. 11° 22'. E. long. 13° 45'.

REDONDELA, a town of Portugal, in Alentejo; 14 miles E.N.E. of Evora. N. lat. 38° 33'. W. long. 7° 22'.

REDONDOS, a town of Portugal, in the province of Beira; 17 miles S. of Coimbra.

REDONDELO, Fr., in Magi, a doubled interval in the octave above a single interval. The octave of the octave, with us, is called the 15th. See INTERVAL.

REDOUBT, or REDOUTE, Reduit, in Fortification, a small square fort, without any defence but in front, used in trenches, lines of circumvallation, contravallation, and approach; as also for the lodging of corps de garde, and to defend paflages. See FORT.

They are usually figures of three, four, five, or six sides, encompassed with a ditch, and a bank of earth, which consists of two parts, called rampart and parapet.

In marshy grounds, redouts are often made of stone-work, for the security of the neighbourhood; their face consists of ten to fifteen fathoms; the ditch round them from eight to nine feet broad and deep; and their parapets, which are cut into embrasures and merlons, have the same thickness. See REDUCT.

The inner sides of square redouts are usually between the limits of twelve and thirty-two yards; and when they are to be defended by musketry, the number of men necessary to the defence may be thus determined; half the side figured gives the number of troops; and twice the square root of a given number of men, shews the length in yards of the side of a square redoubt proper to contain them.

To construct a square redoubt.—Mark out a square, whose side is adapted to the number of troops allotted for the defence, as A B (Plate VII. Fortification, fig. 5.) for the inside of the rampart. About this square, at the distance of ten or twelve feet, describe another square, whose side, C D, is the inner boundary of the parapet; make a parapet of about nine or ten feet thick, whose outline is the line E F; leave a berm about three or four feet broad, whose side is G H; and dig a ditch about sixteen feet wide, and about six or seven feet deep, which should be rounded before the angles of the redoubt. Make the rampart from four feet to nine or ten feet high; let the parapet be six or seven feet higher, and let the foot-bank be four feet and a half lower than the crown of the parapet. On that side most secure from the enemy, make a bridge across the ditch, and a palisade through the rampart, about four or five feet broad when the defence is musketry, about nine or ten feet broad when cannon are to be used; and flit up the palisade by a strong gate. If the redoubt is to be defended by cannon, both the rampart and parapet should be at least five or six feet thicker. In order to make the fire pretty nearly equal on all sides, and sufficient for defending the angles of the work, M. Clairac has contrived to cut the inside of the parapet into notches, whose two sides, of a yard each, are at right angles to one another, and make half-right angles with the sides of the work; the manner of which, and its defence, are plainly shewn in the figure, where the lines with dots at the ends represent the fire three different ways from the same side.

For the method of constructing flanked redoubts, see FORT.

A detached redoubt is a kind of work resembling a ravelin, with flanks, placed beyond the glacis; such as B (Plate V. Fortification, fig. 6.) They are made in order to occupy some spot of ground which might be advantageous to the besiegers; and likewise to oblige the enemy to open their trenches farther off than they would otherwise do. Their distance from the covert-way ought not to exceed a hundred and twenty toises, that they may be defended by muskets-shot from thence. The gorge, a b, is forty toises; the flanks, a c, b f, which are perpendicular to the gorge, ten; and the faces, e d, f d, thirty; the ditch before it is six toises, ending in toises at both ends; the covert-way, four; the branches of the covert-way about forty-two toises long; the faces of the places of arms, p, s, which are perpendicular to the branches, ten; and the other, which is parallel to them, fourteen. The communication from the covert-way to the redoubt is five or six toises wide; and there is a traverse made just at the cutrance, and another in the middle when it is pretty long. The parapets of this communication terminate in a slope or glacis. Robertson’s Marine Fortif. p. 29, &c. Muller’s Fort. p. 43, &c. See ARROW.

Redoubts are also small works of the same form made in a ravelin.

REDOUTE, CALE or DONjon. See REDUCT.

REDOUTES EN CREMAILLERE, differ from other redoubts by having the inside line of the parapet broken, so as to resemble a pot-hook, or the teeth of a saw; by which a greater fire can be brought to bear upon the defile than if only a simple face was opposed to it, and consequently the palisade is rendered more difficult.

REDOUTES DE TERRE, Fr. redoubts that are hastily thrown up, and made with earth, for the purpose of securing entrenchments, circumvallations, palisades of rivers, &c.

REDOUTES DE MACONNERIE, Fr. redoubts made of mason-work; generally constructed in places where an enemy might derive advantage from establishing himself; they are likewise built upon the fallant angles of the glacis.

REDOUTES CAFEINATES, Fr. cafedated redoubts, or such as are arched over and, made bomb-proof. Those constructed for the defence of Gibraltar, and for the security of Dover castle, are of this description.

REDOUTES A MACIBACULU, Fr. are those which are made of brick or stone-work several stories high. The highest story juts out about one foot beyond the wall that surrounds or fronts the redoubt.

REDRESSING, the rectifying or setting any thing straight again.

Trees and other plants have a natural faculty of redressing themselves, when, by any external cause, they are forced out of the perpendicular.

In the moral lenity, to redress grievances, is to reform or remove them. The redress of injuries is the object with a view to which courts of justice are instituted in every civilized society; in order to protect the weak from the insults of the stronger, by expounding and enforcing those laws, which define rights and prohibit wrongs. This remedy is,
Red

Redgill, To, in Military Language, is to put a folder through the first elements of military training. Every folder, after his return from long absence, must be redrilled before he is permitted to act in the ranks of a company.

Redruth, in Geography, a considerable market-town in the east division of the hundred of Penwith, and county of Cornwall, England, is situated on the road from Lander, in the Land's-End, at the distance of 262 miles S.W. from London. It occupies the declivity of an eminence in the very centre of the mining district, and derives its support entirely from the mines. Dr. Pryce supposes it to have been a town in Saxon times; but if so, the records of its history during that period have been entirely lost. It is first mentioned in the year 1352, when William Baffet, then proprietor of the manor, obtained for the inhabitants the privilege of fairs and markets. In 1502 a similar grant was made in favour of John Ballif, esq.; and in the reign of the first Mr. Bulwer of Morrall procured a charter for a market on Fridays, which was confirmed by King Charles II. At present there are two weekly markets, held on Wednesday and Friday; and three annual fairs, chiefly for cattle and Ozier manufactures. The tolls of two of these fairs and the markets belong to the Baffet family; and the other fair, to lord de Dunstanville, the descendant of the Baffets. The increase of this town, since the commencement of the copper mines in the last century, has been as fix to one, as appears by the average of baptisms. According to the population return of 1801, it contained 664 houses, and 4924 inhabitants; but in 1811 the houses were returned as amounting to 879, and the inhabitants to 5023 in number.

Redruth consists chiefly of one long street. The church, the living of which is a rectory, was built, in 1770, by lord de Dunstanville, in the stead of a more ancient one. This building is situated about half a mile from the town. Here are the remains of a chapel of ease, dedicated to St. Rumon, which has been unroofed for many years. In Redruth are meeting-houses for Quakers and Anabaptists, besides two for Methodists in the town, and a third in the north part of the parish. In 1803, a large school-house was built here by subscription, and a master placed in it by the same means; but the subscription having been discontinued, the school is now kept open by the master on his own account.

Among the numerous mines in Redruth and the contiguous parishes of Gwennap, Kenwyn, and St. Agnes, those denominated the Gwennap mines are considered to be the principal. These lie to the south-east of Redruth, in a part of the county where the tin and copper lodes are peculiarly rich, and in some places intermingle each other. The country of the united mines of Huel-Virgin, Poldice, and Huel-Unify, is schiitus; that of Huel-Jewell, Huel-Goldar, and Trefvan, is granite; and it has been remarked, that the metallic veins mostly obey the course of the granite mountains, and run very nearly parallel with them. The united mines employ about 600 men, of whom 400 work under ground. The water is drawn off by four immense steam-engines, one of the cylinders of which is nearly seven feet in diameter. The Huel-Virgin mine is 150 fathoms deep, and is extremely productive; but the Huel-Unify and Poldice mines are still more rich, and are wrought to such advantage, that the proprietors usually earn 16,000l. to 20,000l. per annum. The depth of the Poldice mine is 170 fathoms; but at present it is not worked at a lower depth than 140. This is one of the oldest mines in the county, and yields a yellowish copper ore, a rosin tin, and a few tones of galena. The Huel-Goldar mine is 120 fathoms below the surface, and is wrought at the expense of about 1000l. a month. The North Down mines, nine in number, occupy an extent of two miles in length, and one in breadth, and have their surplus water carried away by the same long adit which runs through the Gwennap mines to the Cannon-Stream works.

Besides the mines, there are several other objects in the vicinity of Redruth not uninteresting of notice. Portreath, about four miles to the north, is a small sea-port for the importation of coal and lime, and the exportation of copper ore to the works in Wales. It is defended by a fort, mounting four guns, and was erected by lord de Dunstanville in the year 1782, and is maintained at his expense. Teidy park, the ancient seat of the Dunstanville family, adjoins Portreath on the south-west. This manor is first mentioned as being in their possession as early as the year 1700, about thirty years before the marriage of Cecilia de Dunstanville, with William Baffet, who carried the Dunstanville estates to the Baffets. The present manor-house is of modern erection, containing a centre, and four detached pavilions at the angles, the whole constructed chiefly of Cornish freestone. The principal rooms are decorated with some good portraits by Vandyke, Kneller, and Sir Joshua Reynolds; and also with a few pieces by Rubens, Carlo Dolci, Bononi de Ferraris, Rembrandt, Borgognone, and others of less note. The park and pleasure grounds attached to this mansion are very extensive; containing about seven hundred acres, finely varied by wood and lawn, and appearing like a well-cultivated garden in the midst of a desert.

We shall now proceed to the account of the mines in the vicinity of Redruth. The most remarkable of these is Carnbrey hill, which Dr. Borlase and others contend ought to be regarded as the grand centre of Druidical worship in this county, almost every kind of monument commonly attributed to the Druids being found, as they allege, upon that eminence. How far this opinion is correct, we shall not pretend to decide; but we may observe, that several late writers maintain, that a part of the suppedom monuments of religion, viz. the caves, are in fact the result of natural convection. No doubt, however, some of them are artificial, and probably belonged to the Druids; and what seems to corroborate this idea is, the circumstance of Redruth being a corruption for Bre-Druth, which signifies the Druids' town. On the summit of this hill is a circular fortification, called the Old Castle, which appears to have been formerly surrounded by a strong wall, and about 300 yards to the eastward, on a ledge of fuculent rocks, stands Carnbrey castle, part of which lays claim to a very high antiquity, but the remainder is of comparatively modern date. The rocks upon which this structure is erected not lying at all contiguous to each other, are connected by five circular arches thrown over the cavities.

On the south-west side of Carnbrey hill is Pendarees, the seat of John Stackhouse, esq. It is a large handsome building, situated on an eminence commanding extensive views over the western parts of the county. In a field contiguous is a large cromlech, composed of three upright stones, and an import. Cwmowen, situated about three miles further to the south-west, has been for several centuries a seat of the family of St. Aubin. The house is deeply embosomed in wood; and contains, besides several pictures of curiosity and value, a large collection of rare and choice prints, accumulated in the portfolios of its present possessor.

RED

REDSEA. See Iron.

REDSTONE, in Geography, a town of Pennsylvania, on the Monongahela; 55 miles N.W. of Pittsburg.

REDUBBORS, those who buy stolen clothes, &c. and, to the end they may not be known, turn them into some other fashion, &c. See Frippery, and REGATON.

REDUCED, in Chemistry. See REDUCT.

To Reduce a Place, in Military Language, is to oblige the governor to surrender it to the besiegers by capitulation.

To Reduce the Circle, is to restore or bring back a battalion or company which has been formed in circle to its original position in line.

To Reduce the Square, is to restore a battalion or battalions which have been formed in a hollow or oblong square to their natural situation in line or column.

REDUCED CHART. See CHART.

To be Reduced, in Military Language, is to be taken off the establishment, or cease to receive pay as soldiers. When a regiment is reduced, the officers are generally sent upon half pay. Sometimes, as at the close of a war, the corps are reduced, and the officers remain upon full pay. Hence are derived the expressions in and out of the break. In the break the liability of being reduced: out of the break signifies the certainty of being kept upon the establishment.

To be Reduced to the Ranks, is to be taken from a superior appointment in a regiment, and to be ordered to the duty of a common soldier. This sometimes happens by way of punishment, when a sergeant or corporal misbehaves. A sergeant, however, cannot, at present, be reduced, except by sentence of a regimental court-martial.

REDUCING SCALE, is a thin broad piece of box, with several lines and scales of equal parts upon it; for turning chains and links into acres and rods, by inspection.

It is used by surveyors to reduce maps and draughts from one dimension to another; it is sometimes also called a varying scale.

REDEUT, REDIUT, or Redoubt, a military term, signifying a piece of ground, intrenched and separated from the rest of the place, camp, &c. for an army, garrison, &c. to retire to, in case of a surprius. Redoubts have been sometimes made for the purpose of securing different posts in a town independent of its citadel. They were proposed by the celebrated Vauban. See DOMIN.

REDUCTION, in Building, a kind of recharge, or little place, taken out of a larger, to make it more uniform and regular; or for some other convenience, as for a little chimney, for alcoves, &c.

REDEUT, or REDUX, among Chemists, is a powder by which calcined metals and minerals are reduced again to their regular, or pure sublimate.

REDUCTION, REDUCTIO, in the Schools, a manner of bringing a term or proposition, which before was opposite to some other, to be equivalent to it.

Reduction is effected by the addition or retenishment of a negative particle. Thus, to reduce this proposition, no man is an animal, to be equivalent to its opposite, every man is an animal, I drop the negative, and say, man is an animal. After the like manner might the term every man be reduced, by adding the negative and saying, there is no man.

REDUCTION of Propositions is used in a more general sense, for any expression of one proposition, by another proposition equivalent to it.

To a reduction, therefore, there are two propositions required, the reduced, and the reducing; which are considered as the extremes of it, and to be connected in the reduction by means of the particle that is, which here has the effect of a copula.

As here, only animals think; that is, animals think, and nothing besides animals thinks. Where the proposition preceding the particle is reduced, and the subject of the reduction; that following the particle reduces, and has the effect of the predicate of the reduction, and the particle that acts as a copula, importing, not barely that the proposition is expressed, but another equivalent one, or, as it were, the same.

REDUCTION of Syllogisms, is a regular changing or transforming of an imperfect syllogism into a perfect one. Or, it is a change of a syllogism in respect of form, by which the necessity of the illation, or inference, is made more evident.

Reduction obtains in syllogisms of the second and third figure; as also in the indirect modes of the first. By it these are all brought to the first.

There are two kinds of this reduction; the one direct, or often, performed merely by a conversion of one or both the premises, or by a transposition of them; as when cum fugere is reduced to celerent: the other indirect, called per impossibile, or ad absurdum; by which the person who denies the goodnese and legitimacy of an imperfect fyllogism, is reduced to affect or grant something absurd and impossible, or contradictory to some other thing maintained by him.

Suppose, e. g. a person granting the premises of the following fyllogism, denies the conclusion: All fraud is prohibited; but some trading is not prohibited; therefore some trading is not fraud. We thus proceed against him if the fyllogism be not good, the antecedent is jilt, but the consequent falf; and, therefore, the contrary of the conclusion must be true: now I take the contrary of the conclusion, which you thus give, viz. all trading is fraud; and of that, with the other premise of the former fyllogism, viz. the major, which you likewise grant, make a new fyllogism; thus, All fraud is prohibited; all trading is fraud: therefore all trading is prohibited. But this proposition, all trading is prohibited, and the other, some trading is prohibited, which you granted me in the first fyllogism, are contradictories.

REDUCTION, in Arithmetic, is the converting of monies, weights, or measures, into the same value in other denominations; e. g. pounds into shillings and pence; or shillings and pence into pounds.

The reductions of the principal monies, coins, weights, and measures, ancient and modern, foreign and domestic, are found under COIN, WEIGHT, MEASURE, POUND, FOOT, &c.

Reduction is of two kinds: 1. Descending, when a quantity is to be brought from a higher denomination to a lower.

This is done by considering how many of the next less denomination are contained in the next greater before, and by that number multiplying the greater.

Thus pounds are reduced into shillings, by multiplying by 20; shillings into pence, by multiplying by 12; and pence into farthings, by multiplying by 4.

Troy pounds are reduced into grains, by multiplying by 2, 24; and avoirdupois hundreds into ounces, by 4, 28, and 16.

2. Ascending, when a lower denomination is to be reduced to a higher.

In order to this, this business is to divide the least by so many of its denomination as are contained in the next greater: thus 24,720 pence, divided by 12, and the quotient by 20, gives 103 pounds.

If there remain any thing in each division, it is respectiv
reduction have been invented. See Practice.

Thus, yards are turned into ells by subtracting a fifth; and into ells Flemish by adding a fifth. Elfs Flemish are reduced into yards by subtracting a quarter. Elfs Flemish reduced into English by multiplying by 6, and cutting off the right-hand figure.

Great pounds of silk of twenty-four ounces are reduced to pounds of sixteen ounces by adding one-half; and pounds of sixteen ounces into pounds of twenty-four by subtracting one-third.

Reduction of Decimals. See Decimals.

Reduction of Fractions. See Fractions.

Reduction of Ratios. See Ratios, Reduction of.

Reduction of Surds. See Surds.

Reduction of Equations. Various algebraical operations are called under this head by different authors; some considering it to be the same as is otherwise, and more properly, called the solution of equations, or the finding of their roots; some define it to be the taking away or exterminating all the unknown quantities except one, otherwise called elimination; others again, under this head, treat of what is more usually termed the transformation of equations; and others again apply it to the de-prebling of an equation, or the reduction of it to another of lower dimensions, which latter seems to us the only operation that can properly be treated of under the above designation. See Resolution, and Transformation.

There are but few cases in which the reduction of an equation can be effected, viz. only when a known relation has place amongst any of its roots, in which case the equation will admit of being reduced as many degrees lower, as there are independent conditions known to have place. So that if the relation be only between two roots, which is one condition, the equation may be reduced two degrees; if the relation extend to three roots, it may be reduced three degrees; and so on.

The conditions or relations more commonly considered, are those in which the roots of an equation form an arithmetical or geometrical progression, and when an equation has any number of equal roots. The two former relations seem rather objects of curiosity than utility, as it is not probable that an equation should have such relations obtain between its roots; but with regard to equal roots they may frequently arise in the solution of various problems. When any geometrical or physical problem is proposed, the number of its possible solutions is generally limited, and therefore the ultimate result arising out of such investigation ought to be an equation, the number of whose roots agree with the limited number of solutions. But it may happen that the analyst, by not pursuing the best mode of operation, is led to an equation of higher dimensions than is requisite, in which cases, upon investigation, it will always be found that his resulting equation has some number of equal roots, which being taken away, will reduce the equation to one of lower dimensions, which gives the proper number of solutions to the original problem. As to the cases in which the roots of an equation form a geometrical progression, they occur almost exclusively in the solution of binomial equations, having prime indices, a property which M. Gauss has turned to a good account in the solution of these equations. See Polygon, and Reciprocal Equations.

Nearly all other relations between the roots of equations are signified for the purposes of framing questions, and exhibiting the ingenuity of authors and their students. 1. To ascertain whether a proposed equation has any equal roots.

Let \[ x^n + a x^{n-1} + b x^{n-2} + \ldots + \gamma x + \phi = 0 \]

be any equation whose roots are \( a, b, c, d, \ldots \), and from the known theory of equations we have

\[
(x - a) (x - b) (x - c) (x - d) \ldots
\]

And it may be shewn also, that the equation \( m x^n + (m - 1) x^{n-1} + (m - 2) x^{n-2} + \ldots = 0 \)

is equal to the sum of all the \( m \) equations that can be formed by the different combinations of the \( m \) first roots, taking \( m - 1 \) at a time. (See Waring's Meditationes Algebraicae, cap. 3.) Now if we suppose the first equation to have two equal roots, as, for example, \( a = b \), the above products will become

\[
x^n + a x^{n-1} + b x^{n-2} + \ldots + \phi = 0
\]

and

\[
m x^n + (m - 1) x^{n-1} + (m - 2) x^{n-2} + \ldots = 0
\]

where it is obvious that both the one and the other of these equations have the same factor, viz. \( (x - a) \).

If the equation had three equal roots, it is equally obvious that both equations would have the common factor \( (x - a)^2 \); and generally, if the equation had \( p \) equal roots, they would both have the common factor \( (x - a)^{p-1} \).

Therefore, when it is proposed to find whether a given equation have equal roots, we must from the proposed equation draw the derived equation as above, (which, it will be, observed, is the same as would arise from taking the fluxion of the first, leaving out of course the \( x^n \)s) and find by the usual methods, whether these two functions have any common measure; which, if they have, will furnish us with the equal root fought; and consequently the original equation may then be reduced by division to another of two degrees, lower dimension for two equal roots; of three degrees, lower for three, and so on.

Exam. 1.—It is required to find the equal roots of the equation \( 4 \times^4 - 48 \times^2 - 128 = 0 \).

Here the derived equation is \( 3 \times^3 - 48 = 0 \) and the common measure of these two functions is \( x + 4 \); when \( x = -4 \) and \( x = 4 \) are the equal roots; the third root being \( +8 \).

Exam. 2.—It is required to ascertain whether the equation

\[
x^4 + 3 x^3 - 14 x^2 - 12 x + 40 = 0
\]

have equal roots, and what they are.

Here the derived equation is

\[
4 \times^3 + 9 \times^2 - 28 \times - 12 = 0
\]

and the common divisor of the two is \( x - 2 \); whence \( x = 2, 2, \) which are also two of the equal roots. Divide now the original equation by \( x^2 - 4 x + 4 \), and we have

\[
x^2 + 7 x + 10 = 0
\]

whole
whole roots are $-2$, and $-5$; therefore, the four roots of the proposed equation are $2, 2, -2, -5$.

If the roots of an equation be equal, but with contrary signs, the operation is more simple. For, in this case, we have only to change the signs of the roots in the proposed equation, by changing the alternate signs of its co-efficient; and we shall thus have two equations, having necessarily a common quadratic divisor of the form $x^2 - \alpha^2$, which may be found, and the equation depressed as before.

Exam. 3.—Required the roots of the equation $x^4 + 3x^3 - 7x^2 - 27x - 18 = 0$, two of which are equal, but with contrary signs.

By changing the signs of the alternate terms, we have $x^4 - 3x^3 - 7x^2 + 27x + 18 = 0$, the common quadratic divisor of which is $x^2 - 9 = 0$; whence the equal roots with contrary signs are $\pm 3$, and $\pm 3$. Now dividing the proposed equation by $x^2 - 9$, we have $x^2 + 3x + 2 = 0$;

whence $x = \frac{-3 \pm \sqrt{1}}{2} = -2$, and $-1$, which are the other two roots.

On this subject the reader should consult Waring's Meditationes Algebraicae, cap. 3. See also Bonnycastle's Algebra, vols. i. and ii.

Reduction of Interest of the Public Debt. See Fund.

Reduction of Curves. See Curve.

Reduction of a Figure, De/ign, or Draught, is the making a copy of it, either larger or smaller than the original, still preserving the form and proportion.

The great use of the proportional compasses is in the reduction of figures, &c. whence they are also called compasses of reduction.

There are various methods of reducing figures, &c.; the most easy is by means of the pantograph (which see), or parallelogram: but this has its defects. The best and most usual methods of reduction are as follow:

To reduce a figure, as A B C D E (Plate XII. Geometry, fig. 5.) into a less compara.—About the middle of the figure, as $\varepsilon$, pitch on a point; and from this point draw lines to its several angles, A, B, C, &c. and then drawing the line $ab$ parallel to $AB$, or $bc$ parallel to $BC$, &c. you will have the figure a b c d e similar to A B C D E.

If the figure a b c d e had been required to be enlarged, there needed nothing but to produce the lines from the point beyond the angles, as $A = \varepsilon$, $B = \varepsilon$, &c. and to draw lines $\varepsilon A$, $\varepsilon B$, $\varepsilon C$, &c. parallel to the sides $dc$, $eb$, &c.

To reduce a figure by the angle of proportion.—Suppose the figure A B C D E (fig. 6.) required to be diminished in the proportion of the line A B to a b (fig. 7.): draw the indeterminate line $G H$ (fig. 8.), and from G to H, let off the line A B; or on G describe the arc $H I$; let off the line $a b$ as a chord on $H I$, and draw G I. Then with the angle $IGH$ you have all the measures of the figure to be drawn. Thus to lay down the point $t$, take the interval $B C$, and upon the point $G$ describe the arc $K L$, also on the point $G$ describe MN; and upon $a$, with the distance MN, describe an arc cutting the preceding one in $t$, which will determine the side $d e$. And after the same manner are all the other sides and angles to be described. The same process will also serve to enlarge the figure.

To reduce a figure by a scale.—Measure all the sides of the figure, e. gr. A B C D E, by a scale, and lay down the same measures respectively, from a smaller scale in the proportion required.

To reduce a map, design, or figure, by figures.—Divide the original into little squares, and divide a fresh paper of the dimensions required, into the same number of squares; which are to be larger or less than the former, as the map is to be enlarged or diminished.

This done, in every square of the second figure, draw what you find in its correspondent one in the first.

Reduction to the Eclipse of the Moon, is the difference between the argument of latitude, as $NP$, (Plate XIX. Astronomy, fig. 10.) and an arc of the ecliptic $NR$, intercepted between the place of a planet and the node $N$.

To find the reduction.—The angle of inclination P N R, and the argument of latitude N P, being given, find, by the doctrine of sines, the arc N R; subtract N R and N P from each other, the remainder is the reduction.

Reduction into first Matter, is a term which alchemists formerly used, when they found their substances putrefy, and grow black.

Reduction was more particularly used for the conversion of a dry matter into a liquid, particularly into water; which by the alchemists was held the principle of all things.

The reduction of metals into their first matter, or principles, according to these philosophers, can only be effected by mercury; nothing else being able to loosen the fixed sulphur of metallic bodies, which binds them together.

Reduction, in Metallurgy, is the decomposition of a metallic oxyd, so as to leave the metal in a state of greater or less purity, and exhibiting the sulphur which is so eminently characteristic of metallic bodies.

Reduction is, for the most part, effected by charcoal and a high temperature, either with or without the assistance of fluxes. For the various modes of reduction in actual practice, see the articles of the different metals.

Reduction, in Surgery, denotes an operation by which a dilated, luxated, or fractured bone is reduced to its former place. Reduction, or reposition, is always to be performed before any remedy is applied.

Reduit, in Military Affairs. See Reduct.

Redundancy, or Redundance, a fault in discourse, confuting the use of a superfluity of words.

Words perfectly synonymous are redundant, and ought to be retrenched. Redundancy unnecessarily makes the style weak and languid. See Pleonasm.

Redundant Hyperbola, in Geometry, is a curve of the higher kind, thus called, because it exceeds the conic section of that name in the number of its hyperbolic legs; being a triple hyperbola, with fix hyperbolic legs.

Redundant Interval, in Music, is used for an interval exceeding the truth by a comma.

Some apply redundant to an interval exceeding a diatomic interval by a leptomean minor; but this is more usually called a superfluous interval. See Interval and Second.

Reduplication, in Rhetoric, a figure by which a verile begins with the same word as the preceding one ends with. See Anadiplosis.

Reduplication, in Logic, is a kind of condition expressed in a proposition, indicating or assigning the manner in which the predicate is attributed to the subject.

The usual redupliative words are quaternus, as, so far as, considered as, instead of as, &c. Hence

Reduplicative Propositions, are such in which the subject is repeated, with some circumstances or condition. Thus, Men, as men, are rational; Kings, as kings, are subjects to none but God.

Redutea, in Botany, so called by the late M. Ventenat, in honour of his friend M. P. J. Redouté, one of the most accurate and intelligent botanical draughtsmen, and perhaps the finest botanical painter, ever known. He is the author of a splendid coloured work in folio, on the Lithiaceous
liaconous tribe, including some other beautiful plants allied thereto, which has already extended to the seventh volume; and it is to his pencil that the perfection of most botanical works that have appeared in France, for near thirty years past, particularly the publications of L'Heritier and Ventenat, is owing. — Venten. Jard. de Cels, t. ii. — Poiret in Lamarck Dict. v. 4. 87. — Flas and order. — Monodelphia Polyandra. Nat. Ord. Columnifera. Linn. Malvaeeae. Juff. Gen. Ch. Cal. Perianth inferior, double, permanent; the outer of many minute leaflets; inner much larger, of one leaf, in five very deep segments. Cor. Petals five, roundish kidney-shaped, imbricated obliquely, united at the base to each other, and to the column of the flaments. Stem. Filaments numerous, united below to a conical tube, subdivided and branched above; anthers kidney-shaped. Pifil. Germin superior, ovate, simple; style thread-shaped, swelling upwards, about as long as the flaments; stigma three, obtuse. Peric. Capsule ovate, of three cells and three valves, the partitions from the middle of each valve. Receptacles of the feed three, united into the base of the capsule, alternate with the valves, and nearly equal to them in length, linear, bearing seeds on each edge. Seeds five or eight in each cobate, minutely tinctored, united in two rows on the receptacle, each clothed with dense wool.

Eff. Ch. Calyx double; the outer of many minute leaves; inner in five deep segments. Stigmas three. Capsule of three cells and three valves. Seeds enveloped in wool. Receptacles three, linear, unconnected with the valves.

Obs. Ventenat considers the three distinct receptacles, as affording the most essential distinction, between this and every other malvaceous genus. The woolly feeds, moreover, distinguish it from all except Gossypium, whose large three-leaved outer calyx is abundantly different from Redusta.

The only known species is

1. R. heterophylla. Various-leaved Redentia. Vent. Jard. de Cels, t. ii. — Discovered by Riedel in the island of St. Thomas, and raised in M. Cels's garden at Paris. The plant is herbaceous and annual, and M. Ventenat seemed to think it might serve to decorate our flower-borders, like other annuals of very hot climates, in the open air, being, we presume, raised on a hot-bed in the spring. Every part of the herbage is bespangled with small, whitish, fringed scales, readily seen with a magnifying glass. The root is spindle-shaped, yellowish. Stem erect, twelve or fifteen inches high, about the size of a goose-quill, angular, pitiful, branched, leafy, dark green, many-flowered. Leaves alternate, on longish stalks, spreading widely, ovate, undivided or three-lobed, entire, an inch or inch and half long; paler beneath. Stipules minute, awl-shaped, deciduous. Flowers large, handlike, sulphur-coloured, with a dark purple radiating spot at the base of each petal, solitary, erect, on long, simple, axillary flalses. Segments of the inner calyx nearly linear, half as long as the petals. Style hairy. Capsule the size of a filber. Wool of the seeds of a dirty grey.

We have not heard of this plant in any English collection.

REDUVIA, in Surgery, a word used by some for a whitlow, and by others for a painful crack, or other disorder about the nails, either of the fingers or toes.

REDUX, in Chemisty. See REDUCT.

REDWAETH BAY, or Traeth Coch, in Geography, a bay on the N. coast of the island of Anglesey. N. lat. 53° 17'. W. long. 4° 25'.

REDWITZ, a town of Bavaria, in the bishopric of Bamberg; 4 miles N. N.W. of Kufkstadt.

REDWITZ, a town of Germany, in the principality of Culmbach; 4 miles N. of Bayreuth.

REDWOOD RIVER, a river of America, which runs into the Wabash, N. lat. 40° 19'. W. long. 87° 5'.

REE, or REE, in Commerce. See REES.

REE, Lough, in Geography, an expansion of the waters of the river Shannon, in Ireland, between the county of Roscommon and the counties of Longford and Westmeath, reaching from Lanesborough nearly to Athlone, with several islands, and in some places three miles broad.

REE, in Botany. See ARUNDO.

The root of the arundo donax of Dioscorides, attracts any matter lodged in wounds, if powdered and applied to them with wine; or if it is taken fresh and reduced to powder with an onion, or mixed with honey. (Ortibas in Arb. Cor. lib. iii. cap. 32.) It also removes pains arising from dislocation of limbs, and carries off pains in the hips. The green leaves cut and applied, are said to cure the erysipelas. Poor people boil the flowers in water or in beer, which they mix with honey, and drink, after being filtered, to cure coughs, oppressions of the breath, and consumptions. The ancients made flutes and other musical instruments of the reed. James's Med. Dict.

REE, Barr. See SPARGANUM.

REE, Indian flowering. See CANNA.

REE, Mac. See TYPHA.

REE, in Agriculture, the name of an aquatic plant, infesting boggy lowlands or meadows on the sides of rivers.

The best method of destroying reeds, is by draining the land; for if the drains be cut deeper than their roots it will take away their nourishment, and, consequently, destroy them. Aches, or foot, will likewise sometimes kill them, and so will ploughing up the land, and laying it in high ridges. They always indicate a deep good moist soil, as a bad one will not nourish or support them. There are many different sorts of reeds, but those of the more firm and tall kinds are often of much use in thatching the different sorts of farm buildings, where other better kinds of coverings are scarce, and these abundant. There is also a sort of reed found in Huntingdonshire, and some of the adjoining counties, that is very valuable for the purpose of laying plaster floors with. In other situations, reeds of the other kinds may be met with, that may be found useful for different purposes either of the farmer or in the arts. In such situations they may be cultivated with advantage as an article of profit: and it may often be more beneficial than to have them destroyed, especially where they are of a valuable nature, and where the land is of too moist and boggy a quality to be ever fully reclaimed and brought into either the state of good arable or meadow ground. Slips on the sides of large rivers or brooks are likewise, frequently, the most advantageously, conveniently, and profitably kept under reed crops, as the overflow of the waters prevent their being usefully managed in any other manner. There are other situations, as those about the borders of large ponds, lakes, and other waters, where they may be preferred with far greater propriety than having them destroyed, provided even that can be accomplished without difficulty, as not any thing more valuable can in general be raised in such places. They are, however, by no means to be continued wherever any better crop will grow and succeed.

REE is also a term applied to such straw of the wheat or rye kinds as has not been bruised by threshing or in any other way.

REE, Hedge, in Gardening, that sort of hedge fence which is formed from reeds. They are a sort of temporary internal fences made with these dried materials which may be had cheap, and be expeditiously formed into hedges by the affiliane
 ance of polt and ralling, being of great utility for occasional use in gardens, to incline particular internal spaces of ground, so as to afford shelter to certain feeding plants, both in nurseries and large kitchen gardens; and in some nurseries, to form places of shelter for many sorts of feeding trees and shrubs, &c., which being tender whilst young, require the shelter of a fence in winter to break off severe or cutting blasts two or three years, till they gradually gather strength and a greater degree of hardiness. They are also useful in training several sorts of wall-fruit-trees against, to form them for rows, or what are called trained trees; admitting of planting trees against each side of them, six, eight, or ten feet alinder. See Nursery.

And in large open kitchen-gardens they are occasionally made use of to incline the melonary, or place for ralling early melons and cucumbers in, and often as crofts internal fences, under which to form warm borders for the purpose of ralling various early crops of eculents.

The proper sort of reeds for these fences are the dried stems of the common marsh reed, which grows in great plenty by river sides, and in lakes, and marly places, furnishing a crop of items annually fit to cut in autumn, when they should be bound in bundles, and stacked up, or hauled, to remain for use.

These fences are sometimes erected in fixed ranges, and sometimes formed into moveable panels. In the first mode, some flat polls should be placed fix or eight feet alinder, and five or six fix high, and from poll to poll carry two or three ranges of flat thin railing, one range near the bottom, another near the top, and a third in the middle; against this railing, the reeds must be placed about two inches thick, having other ralling fixed directly opposite; so that the reeds being all along between the double ralling, the bottoms ralling either upon a plate of wood, or let into the ground, but the former is preferable; and as soon as one panel is formed, the railing should be nailed as close as possible, driving some long spike-nails through each double ralling, or binding them with strong withy bands, or tar rope-yarn, but nailing is the best, in order to bring them as close as may be, to secure the reeds firmly in the proper position; the top should be cut even afterwards.

In the better method, a frame-work of railing should be prepared as above, each panel fix or eight feet long, and the reeds placed therein as before directed; then, where they are intended to be placed, polls must be ranged fix or eight feet distant to support the different panels. Or sometimes the panels may be placed inclining against the wall or other fence, in time of severe weather, when the borders are narrow. These sorts of fences are now however in much less use in gardening than formerly.

**REEF Ronds,** in Rural Economy, a provincial word, signifying plots or beds of reed, or the swamps in which they grow.

**REEF, Ezekiel's.** See Ezekiel's Reed.

**REEF, Calamus,** likewise denotes a Jewish measure, otherwise called canna.

**REEF, in the Manufactory of Tapestry.** See Tapestry.

**REEF Sparrow**, in Ornithology. See Emberiza Schoenicula.

**REEF, Point**, in Geography, a cape on the W. coast of the island of Antigua. N. lat. 17° 12'. W. long 61° 36'.

**REEHAM.** See REEPHAM.

**REEDS,** in a Fire-ship, are made up in small bundles of about twelve inches in circumference, cut even at both ends, and tied each with two bands. There are two kinds of them; the long, which are four feet; and the short, which are two feet five inches in length. Some of them are finely dipped, i.e., at one end, the reet are dipped at both ends, in a kettle of melted composition. After being immersed about seven or eight inches in this preparation, and then drained, they are sprinkled over with pulverized sulphur upon a tanned hide. See Fire-ship.

**REEDSBOROUGH**, in Geography. See REEDSBOROUGH.

**REEDESTOWN.** See Strong.

**REEDEY Creek,** a river of New Jersey, which runs into the Atlantic, N. lat. 39° 55'. W. long. 74° 16'.

**REEF Island,** an island of America, in the Delawar river, 50 miles below Philadelphia, and 20 miles from Bombay Hook, about three miles long and not more than one-fourth of a mile wide. This island was formerly banked in, but is now under cultivation, and overflowed in high tides. It is the rendezvous of outward-bound ships in autumn and spring, waiting for a fair wind. Here is a secure harbour at Port Penn, where piers have been erected by the state of Pennsylvania. On each side of the isand is a channel; but veffels, especially of the larger kind, choose to keep the eastern side.

**REEF River.** See SALUDA.

**REEF River Shool,** a port-town of America, in Greene
dfield county, South Carolina.

**REEF (reef, Dutch),** in Navigation, denotes a certain portion of a fall, comprehended between the top or bottom, and a row of eyelet-holes parallel to it. The intention of the reef is to reduce the surface of the fall in proportion to the increafe of the wind; for which purpose there are several reefs parallel to each other in the superior falls, by which they may be still farther diminished, in order to correspond with the several degrees of the gale. The top-falls of ships are usually furnished with four reefs, parallel to the yard; and there are always three or four reefs parallel to the foot of those main-falls and fore-falls which are extended upon booms; a circcumstance common to many of the small veffels. Falconer.

A bag-reef is the fourth, or lower, reef of a top-fail. A balance-reef crosses boom-main-fails diagonally, from the nock to the end of the upper reef-band on the after-larch. This is used to contract the fails in a storm. Reef also denotes a chain of rocks, lying near the surface of the water.

**REEF-Band,** in Sea Language, a piece of canvas, fewed across the fail, to strengthen it in the place where the eyelet-holes of the reefs are formed.

**REEF-Hanks,** short pieces of log-line or other small line, fastened at certain distances to form the reefs of boom-fails.

**REEF-Tackle,** is a rope which passes from the deck to a block at the top-mast head, and thence to another block at the top-fail-yard-arm, where it communicates with another rope, called its pendant, that runs downwards through a hole in the yard, and is afterwards attached to a cringle, a little below the lowest reef. It is used to pull the sheets of the reefs close up to the extremities of the top-fail yards, in order to lighten the fail, the weight of which would otherwise render it very difficult to perform this operation. Falconer.

**REEF Island,** in Geography, a small island in the East Indian sea, about 50 miles from the W. coast of Sumatra. S. lat. 4°. E. long. 101° 3'.—Alfo, a small island in the East Indian sea, near the N. coast of the island of Celebes. N. lat. 6° 58'. E. long. 122° 48'.

**REEFING,** in Sea Language, the operation of reducing a fall, by taking in one or more of the reefs, which is performed by lines, points, or hitches. The top-fails are always
always, and the courses generally, reefed with points, which are flat braided pieces of cordage, whose lengths are nearly equal to the circumference of the yard. These, being
indefinite in the eyelet-holes, are fixed in the sail by means of
two knots in the middle, one of which is before, and the
other behind the reef-band. In order to reef the top-fails
with greater facility and expedition, they are lowered down,
and made to fliver in the wind, which considerably relaxes
their tension. The extremities of the reef are then drawn
up to the yard-arms by an assembly of pulleys communicating
with the deck, termed the reef-tackle; and they are securely
fastened to the yard-arms by small cords, called earings.
The space of fail, comprehended in the reef, is then laid
smoothly outward, in several folds or doubles; and the
whole is completed by tying the points above the yard,
so as to bind the reef close up to it. The courses of large
ships are reefed either with points or small cords, which
are thence called reef-lines. In the latter case, the line is
pinned spirally through the eyelet-holes of the reef, and
over the head of the fail alternately, and afterwards strained
as tight as possible. It must be observed, however, that the
reef-line is sometimes pulled round the yard, and sometimes
only round the head of the fail; and each of these methods
has its advocates. But if it should appear effential to pre-
vent the friction by which a fail is galled between the line
and the yard, and as the rope-bands are sufficient to fullam
the effort of the fail, it is better to pass the line only round
the fail, provided that the turns are inserted through the
rope-bands; a circumstance carefully practised by every
skillful failor. The same reason may be alleged in favour of
tying the points of the courses in the same manner; i.e.
the after-end of the point should be thrusted forward between
the head of the fail and the yard; and the fore-end of the
fail point should come aft over the head of the fail and also
under the yard; and thus crossed over the head of the fail,
the point should be extended, and the two ends brought
over the yard; and tied on the upper side of it as straight
as possible.

When a fail is reefed at the bottom, it is done by knittles,
which, being thrusted through the eyelet-holes of it, are tied
firmly about the space of canvas of which the reef is com-
posed, and knotted on the lower side of the bolt-reef.
These knittles are accordingly removed as soon as the reef
is let out. Falconer.

REEK, in Rural Economy, a term provincially used for
flack. See Stack and Rick.

REEK-Staffel, a term applied to a frame of wood placed
on flone, on which the mow or flack is railed. It is some-
times written Reek Staffeld.

REEL, in the Manufactory, a machine serving for the
office of reeling.

There are various kinds of reels; some very simple,
others very complex. Of the former kinds, those most in
use are,

1. A little reel, held in the hand, consisting of three
pieces of wood, the biggest and longest whereof (which
does not exceed a foot and a half in length, and a quarter of
an inch in diameter,) is traversed by two other pieces dif-
cerent different ways.

2. The common reel, or windlass, which turns upon a
pivot, and has four slings, traversed by long pins, or slicks,

of which the skain to be reeled is put on, and which are drawn
closer or opened wider, according to the skain.

Other reels used in particular arts, are explained under
their particular articles; as the reel used in mulling of silk,
under the article Milling; and that in the reeling or
winding of silks, under the article Silk, &c.

Reels, to reel ropes on from a six-thread ratline to a two-
inch rope, have four ribs fixed at each end in a flat circular
piece of wood; and round the edges are blades, or handles,
to turn them; one of the circular pieces is called the head,
and is made to slide off for taking the coil away. They turn
on an iron spindle, and are from ten to thirty-six inches long,
and from twelve to eighteen inches diameter. The Bench-
reef used by fail-makers is similar to a spinning-wheel, and
is used to expedite winding the skain from the skains to the
wint-reef. Log-reefs have several ribs fixed in a circular
piece of board at each end, and turn or run upon a spindle,
having a handle at one end. (See Log.) Twin-reefs,
used by fail-makers, are short cylindrical pieces of wood,
hollowed in the middle to receive the twine, with a hole
through the middle for the spindle. Those used by rope-
makers have four oak bars, about eighteen inches long,
framed together at the ends on a wooden spindle; one of the
bars slides, for the convenience of taking off the twine. The
Tarn-reef consists of a circular board fastened horizontally
on the middle of a piece of oak four inches square, and six-
ten long, with a hole through its middle to receive a bolt,
on which it turns as its axis, and is used to wind spun-
yarn off the coil. The Hamb-reef is a narrow board, with
three or four holes at each end, in which pegs are fixed for
reeling marine and other lines.

REEFFOOT, in Geography, a small navigable river of
America, in Tennessee, which discharges itself into the river
Mississippi, about 35 miles S. of the Ohio. It is 30 yards
wide, seven miles from its mouth. One of its branches rives
on the borders of Kentucky.

REELING, in the Manufactory, the winding of thread,
silk, cotton, or the like, into a skain, or upon a bottom, to
prevent its entangling.

It is also used for the charging or discharge of bobbins,
or quills, to use them in the manufacture of different stuffs,
as thread, silk, cotton, &c.

Reeling is performed different ways, and by different
engines.

REEM, in Zoology. See Rhinoceros Unicornis.

REEMING, a term used by caulkers for opening the
seams of the planks with reeming-irons, that the oakum
may be more readily admitted. To make any hole larger
is also termed reeing.

Reeming-Irons, are the largest irons used by caulkers in
opening the seams.

REEMSTOWN, or REAMSTOWN, in Geography, a
small port-town of America, in Lancaster county, Pennsyl-
vania, situated on a stream which runs into Calico creek,
a water of Coneloga, which falls into the Susquehannah;
26 miles N.E. of Lancaster.

REEN, a river of Norway, in the province of Drontheim,
which runs into the Glomme; 20 miles N. of Opal.

REEEN Moss, a name used by some for the mountain
coral-sinews, or rein-deer moss.

REENSENBERG, Theocarus, in Biography, a celebrated
Danish poet, was born at Viborg in 1656, where he was
educated. In 1680 he set out on his travels into foreign
countries, after having undergone an examination by the
theological faculty, and he returned to Denmark in 1682.
In 1723 he was appointed fourth judge in Jutland. In
1730 he became councillor of justice, and he died in 1742.
His poetical works were published at Copenhagen in 1769,
by his grandson Tidmann, with a preface by Kofod Anker,

REENSEDKLOSSER, in Geography, a town of Norway; 12
miles N.N.W. of Drontheim.

RE-ENTER.
RE-ENTERING ANGLE, in Fortification. See Angle, and Construction, according to M. Vauhan's first method.

RE-ENTRY, in Law, the refusing or retaking that poisselion which any one had lately forgone.

As, if I make a leaf of land or tenement, I do thereby forego the poisselion; and if I condition with the lefsee, that for non-payment of rent at the day, it shall be lawful for me to re-enter; this is as much as if I conditioned to take again the lands, &c. into my own hands, and to recover the poisselion by my own act, without the affittance of judge or other process. But words in a deed give no re-entry, if a clause of re-entry be not added. (Wood's Infl. 140.)

All persons who would re-enter on their tenants for non-payment of rent, are to make a demand of the rent; and, to prevent the re-entry, tenants are to tender their rent, &c. (1 Infl. 201.) If there is a lease for years, rendering rent, with condition, that if the lefsee affigns his term, the leffor may re-enter; and the lefsee affigneth, and the leffor receiveth the rent of the affignee, not knowing or hearing of the affignment, he may re-enter, notwithstanding the acceptance of the rent. (§ Rep. 65. Cro. Eliz. 555.) See Rent. A feoffment may be made upon condition, that if the feoffor pay to the feoffee, &c. a certain sum of money at a day to come, then the feoffor to re-enter, &c. Litt. § 322. See Entry and Use.

REEPHAM, in Geography. See Reepham.

REE COUNTY. See Reet.

REEKSOE, in Geography, a small island of Denmark, in the Great Belt, near the coast of Zealand. N. lat. 55° 32'. E. long. 11° 7'.

REE, Reis, or Reis, in Commerce, monies of account in Portugal, 1000 of which make a milræs or milre. In the notation of accounts, the milrees are separated from the rees by a crooked cypher, called "Cifroa," and the milrees from the millions by a colon; thus Rs. 2: 700 : 500, means 2700 mil. and 500 rees. The cruadto of exchange, or old cruadto, is 400 rees; the new cruadto, 480 rees; the teetion, 100; the vintin or vintem, 20 rees. Thus the milre is 4½ old cruadtos, 2½ new ditto, 10 teetions, or 50 vintins.

The gold pieces, coined before 1722, are now 20 per cent. higher than their original value; so that the old dobras, coined at 20,000 rees, are worth 24,000; the liobnoines or moidores, coined at 4000 rees, are worth 4800; and the halves and quarters in proportion; but few of these coins are now in circulation. The gold coins, struck since 1722, are the dobra of 12,800 rees; the meia dobra, Joaneo, or Portugal piece of 6400 rees; the half Joaneo, of 3200; the dezefes titos, of 1600; the quintino, of 1200; the oito titos, of 800; the old cruadto, of 400, now very scarce; and the new cruadto, of 480 rees. The silver coins are new cruadtos, of 480 rees; halves, quarters, and eighths, or pieces of 240,120, and 60 rees; teetions of 100, and halves of 50; and vintins of 20 rees. There are also copper pieces of 10, 5, 3, and 1½ rees. The pieces coined in Brazil, called patacas, of 600 and 640 rees, are current only in that country, and their intrinsic value is 10 per cent. less than that of the Portuguese coins. There is, besides, a gold milre, struck for the Portuguee poisselions in Africa, and also a silver coin, of the value of 12 macutas, or 600 rees; the macuta being a money of account, worth 50 rees. The Spanish patacas, or dollar, are reckoned at Lisbon at 830 rees, more or less.

Portuguese gold coins are 22 carats (the mark fine being 24 carats), wrought gold is 20½ carats, and gold dull from 21½ to 22 carats fine. The fineers of silver is expressed in dinheiros and grains, the mark fine being 12 dinheiros, and the dinheiro subdivided into 24 grains. Silver coins are 10 dinheiros 10 grains fine, and wrought silver 10½ fine.

The rate of coinage of gold and silver coins is as follows: 8 dobras of 12,800 rees, 16 Joaneos of 6400 rees, 32 half Joaneos of 3200 rees, 64 dezefes titos, 128 oito titos, or 256 old cruadtos, are to weigh a Portuguee mark of gold, 22 carats fine. Hence (the mark being 3542 English grains) the dobra contains 4421 grains; the piece of 6400 rees 22½ grains of English standard gold, and the other pieces in proportion. These coins, moreover, are not, in general, exactly 22 carats fine; but there is a remedy which amounts from 2½ to 2½ of a carat; and the new cruadtos are found to be only 21½ carats fine. The silver coin is 10 dim. 10½ gr. as above; and the mark is coined into 15½ new cruadtos; hence the new cruadto weighs 3451 Portuguese grains, or 265 English grains; halves, quarters, and eightths, in proportion. It, therefore, contains 2584 grains of English standard silver. The gold piece of 6400 rees is worth 35½. 11d. Sterling; and the old cruadto, 22, 3d.; and thus the miiræ, valued in gold, is worth 67½ d. Sterling. The new silver cruadto is worth about 21, 9d. Sterling; and, therefore, the miiræ, valued in silver, is worth 69½ d. Sterling. Gold is to silver as 16 to 1.

At Bombay each quarter of a rupee is divided into 100 rees. See Rupee.

REE, in Geography, a town of the duchy of Cleves; 8 miles E. of Cleves. N. lat. 51° 37'. E. long. 6° 30'.

REE u. Ain, or Rejina, a town of Asiatic Turkey, in the province of Diarbekir; 80 miles S. of Diarbekir.

REEZT, a town of the New Mark of Brandenburg; 50 miles N.E. of Cufmir. N. lat. 53° 18'. E. long. 15° 56'.

REEVE, in Ornithology, the name of a bird which is the female of the avis pugnax; the male of which, from the long feathers round his neck, is called the ruff. See Tringa Pugnax.

REEVE of a Church, is the guardian of it, or the churchwarden.

So bijre-reg is the sheriff, or guardian of a county; and port-reve, the warden of a port or haven.

REEV'NE-LAND. See Reveland.

REEVING, in the Sea Language, is the putting a rope through any hole, as the channel of a block, &c. Hence, to pull a rope out of a block, is called unreeving.

RE-EXCHANGE, in Commerce, a second payment of the price of exchange, or rather the price of a new exchange, due upon a bill of exchange that comes to be protellet; and to be refunded the bearer, by the drawer or indorser. See Exchange.

The occasion of re-exchange is, when the bearer of a bill of exchange, after protesting it, for want either of acceptance, or of payment, borrows money on his own promis, bond, or the like; or draws a bill of exchange, in the place where the payment was to be made, on the person who furnished the first for which he pays a second exchange; which, being added to the first already paid, the drawer of the first bill is answerable for two exchanges, properly called exchange and re-exchange.

The bearer of a protellet bill has a right to recover both the one and the other on the drawer. Yet the simple protestation which the bearer makes in the act of protest, that he will take up a like sum at re-exchange, for want of his bill being accepted or paid, is not sufficient to entitle him to demand the reimbursement of his re-exchange, unless he make it appear, that he has actually taken up money in the place on which the bill was drawn.

Otherwise the re-exchange will only amount to the restitution of the first exchange, with interest, the expenses of protestation, and those of the journey, if there have been any.

4 C 2
It a bill of exchange, payable to the bearer or order, come to be protested, the re-exchange is only due upon the drawer for the place where the remittance was made, not for those places where it may have been negotiated; at least the drawer has a right to be refunded his re-exchange for those places by the indorser.

Indeed, the re-exchange is due from the drawer upon all places where a power of negotiation is given by the bill; and upon all others, if the power of negotiating be indefinite.

Lastly, the interest of the re-exchange, of the expenses of the protest, and the journey, are only due from the day of the demand.

It is supposed to be the Gibellina driven out of Italy by the faction of the Guelfs, and sheltered at Amsterdam, who first established the custom of re-exchange, on pretence of the interests, damages, and expenses they underwent, when the bills given them for the effects they had been obliged to abandon, were not accepted, but came to be protested.

RE-EXTENT, in Law, a second extent made upon lands or tenements, on complaint that the former extent was partially made. See Extent.

REFEH, in Geography, a town of Egypt, on the coast of the Mediterranean, anciently called "Raphia." (which fee); 18 miles N.E. of El Arish.

REFECTION, Refeption, among Monks and Ecclesiastics, a spare meal or repast, full sufficient for the support of life.

Refection is also used, in Ancient Authors, for a duty or service incumbent on any person to provide meals for ecclesiastics, or even for princes.

REFECTORY, or Refectuary, Refectatorium, a spacious hall in convents, and other communities, where the monks, nuns, &c. take their refectious or meals in common.

The refectory of the Benedicite of St. George at Venice, designed by Palladio, is one of the finest in the world. Davier.

REFERENCE, in Writing, &c., a mark relative to another similar one in the margin, or at the bottom of the page, where something, omitted in the text, is added; and which is to be inserted either in reading or copying. A copyist must be very expert at taking references.

References are also used in books, where things being but imperfectly handled, the reader is directed to some other part or place where they are more amply explained.

Dictionaries are full of references, denoted by see or vide.

By means of these references the dictionary writer fettles a correspondence between the several parts of his work, and may give his dictionary motto of the advantages of a continued treatise.

Indices or tables are only references to the several parts of the work where the several matters are handled.

REFERENCE, in Law, denotes the finding of any matter by the court of chancery to a matter; and by the courts at law, to a prothonotary, or seckary, to examine and report to the court. (2 Litt. Abr. 432.) If a matter in difference is referred to the seckary, and one of the parties will not attend at the time appointed, after notice given, to hear the business referred; the other party may proceed in the reference alone, and get the seckary to make his report without hearing of the party not attending. (2 Litt. 432.)

A question of more law arises in the course of a cause in chancery, whether, by the words of a will, an estate for life or an entail is created, or whether a future interest devised by a will, or by a settlement will operate as a remainder on an executory devise; it is the practice of that court to refer it to the opinion of the judges of the court of king's bench, or common pleas, upon a case stated for that purpose, in which all the material facts are admitted, and the point of law is submitted to their decision; who thereupon have it solemnly argued by counsel on both sides, and certify their opinion to the chancellor: and on such a certificate the decree is usually founded. It seems, therefore, that the matter of the rolls, sitting for the chancellor, may make such reference; but not when sitting at the rolls. 2 Bro. C. C. 88.

The court of exchequer is both a court of law and of equity: therefore, if a question of mere law arises in the course of the exercise of its equitable jurisdiction, the barons will decide upon it in that suit, without referring it to another jurisdiction. Bl. Comm. iii.

REFERENDARY, REFERENDARIES, in Ancient Customs, an officer who exhibited the petitions of the people to the king, and acquainted the judges with his commands.

An officer of this kind, Spelman observes, we had in England, in the time of the Saxons. The like office was afterwards discharged by others, called masters of requels.

REFINING, in Metallurgy and Asfaying. In the former it signifies the means of obtaining metals from their ores, and from any other impurities, natural or artificial; for example, the metals under their respective heads. In the latter it is employed for ascertaining the quantity of the noble metals in the different alloys; for which see CEPPEL; where the methods of refining in the furnace are fully treated. And for the humid procels called paring, see GOLD.

It may be proper here to observe, that although the procels of paring by nitric acid is still practiced, we are inclined to recommend the method proposed by Bergmann, which consists in dissolving the alloy of gold and silver in nitro-muriatic acid. The silver falls to the bottom in the shape of muriate of silver, and the gold is precipitated by the green sulphate of iron. The gold, by this means, is obtained perfectly pure, which is seldom the case in the procels of paring. The trouble of telling to know what silver to add to the alloy, to make the gold equal to one-fourth of the silver, will be saved, and, with heat, the nitro-muriatic acid dissolves the gold quite as soon as the silver is dissolved in the common method. The muriate of silver, which is easily separated by washing, may be readily reduced by heating it with soda in an iron crucible. The soda combines with the muriatic acid, and is fuselied in white fumes.

REFINING of Sugar. This operation is begun by several strong lixiviums or leys of lime-water and eggs, shells and all, mixed and beaten together.

The first refining is performed in the Caribbees, and other places, where the sugar-canes are cultivated; and only serves to make the brown or coarse sugars.

When these are imported into Europe, the sugar-bakers take them up, and refine them farther, by a second operation, or rather a repetition of the first.

To render the sugar very fine, fit for confections, &c., they give it a third refining; in which they only use the whites of eggs and their shells beaten together, and thrown into the melted sugar; which is called clarifying the sugar. See SUGAR.

REFINING of Salt-petre. The salt being put into an earthen or iron vessel, as much spring-water is poured on it as sufficies to dissolve it. The vessel is then put over a gentle fire; and as soon as the water begins to boil, alun powder is thrown into it; the proportion is, one pound of alun to one hundred and twenty-eight pounds of salt-petre; and a little vinegar is added. As it boils, the feum is to be taken off; and it is to be evaporated till a pellicle appears on it: and then set to flood.
For the refining of other matters, as camphor, cinnabar, sulphur, falt, borax, &c. see CAMPHOR, CINNABAR, SULPHUR, SALT, &c.

REFRTH VoE, in Geography, a bay on the E. coast of the island of Yell. N. lat. 60° 58'. W. long. 1° 25'.

REFITTING, in Sea Language, designates the repairing of any damages which a ship may have sustained in her sails and rigging, by battle or tempestuous weather.

REFLECTED Ray. See Ray.

Reflected Vision. See Reflex and Vision.

REFLrCTING, or REFLECTIVE Dial, is a sort of dial, which shews the hour by means of a thin piece of looking-glafs plate, duly placed to call the fun's rays to the top of a ceiling, on which the hour-lines are drawn.

Reflecting Microscope. See Microscope.

Reflecting Level. See Level.

Reflecting Telescope. See Telescope.

REFL:rCTiON, or REFLECTION, in Mechaniz, the return, or regressive motion of a moveable, occasioned by the reflaltance of a body, which hindered its pursuing its former direction.

It is controverted whether there be any moment's refl or interval between the incidence and the reflection. For the affirmative fland the Peripatetics, and all who conceive the reflacted motion to be different from the incident one of the fame body. The motion of incidence, according to these authors, is wholly lost, and destroyed, by the reflaltance of the obstacle fluck against; and the moveable is thus rendered absolutely quiet in the point of contact, till a new motion of refleétion is produced in it, from a contrary caufe.

The Cartefians affert the negative; absolutely denying any refl at all between the incidence and refleétion: urging, that if the motion were once destroyed, though but for a moment, there would be nothing to excite it again; but the body would perfwere in that new state, as much as if it had been at refl a thousand years.

Accordingly Rohault, and others, define refleétion to be no other than a change of determination; or a continuation of the former motion in a new direétion.

As, say they, a pendulum, when arrived at its greatest sweep, does not stop; fo a hard body, by flrking on another hard one, does not refl, but pursues its motion the contrary way, according to the established law of nature; and this from the immediate influence or impulse of the caufe that first moved it. But this doctrine is now generally fet aside.

Reflection is conceived, by the lateit and belit authors, as a motion peculiar to elastic bodies, whereby, after flrking on others which they cannot remove, they recede, or turn back by their elastic power.

On this principle, it is afserted, that there may be, and is, a period of refl between the incidence and the reflaction; since the reflacted motion is not a continuation of the other, but a new motion, arising from a new caufe or principle, viz. the power of elasticity.

It is one of the great laws of refleétion, that the angle a reflacted body makes with the plane of a reflacting obficle, is equal to that in which it flruck on that obficle. For the several laws of motion obserfed in the refleétions of bodies, see Percussion.

Reflection of the rays of light, in Optics, is a motion of the rays, by which, after impinging on the solid parts of bodies, or rather, after a very near approach to them, they recede, or are driven from them.

When rays of light arrive at a surface, which is the boundary of two mediums not homogeneous, they continue their progres without deviating from those planes in which their former paths lay, and which are perpendicular to the surface of the mediums, but they no longer retain the fame direction, a part of them, and sometimes nearly the whole, being reflacted back from the surface, while the remaining part is transmitted and refracted, or bent. No instance occurs of the abrupt change of the density of a medium, without a partial reflection of the light passing either into the denser, or into the rarer medium; and the more obliquely the light falls on the surface, the greater, in general, is the reflacted portion. No body is fo black as to reflact no light at all, and to be perfectly invisible in a strong light; although at the surface separating two very rare bodies, as two kinds of gas, the reflection is too faint to be perceptible; but in this case the separation is seldom perfectly abrupt. The quantity of light reflected, when other circumstances are equal, appears to be always greatest when the difference of the optical or refractive density of the two mediums is the greatest.

Thus, the reflection from the common surface of glafs and water is much weaker than from a surface of glafs exposed to the air. Metals, in general, reflect a great proportion of the light falling on them; and even the reflection from the common surface of glafs and mercury appears to be but little weaker than the reflection from the surface of mercury immediately exposed to the air, so that the optical density of the metals must be exceedingly great.

It appears, also, that a portion of the light falling on a reflacting surface, is always transmitted to a certain depth, notwithstanding the apparent opacity of any large masses of the substance. Thus, if we cover a small hole of a window-flutter with the thinnest leaf-gold, we shall find that it transmits a greenish light, which must have passed the reflacting surface, but which, if the gold had been but one ten-thousandth of an inch in thickness, would have been wholly interrupted, and probably in the fame manner as by passing through 700 feet of water. See Light and Refraction.

The reflection of the rays of light from the surfaces of bodies, is the means by which bodies become visible.

And the disposition of bodies to reflact this or that kind of rays most copiously, is the caufe of their being of this or that colour.

The reflection of light from the surfaces of mirrors, makes the subject of catoptrics; which see. See also Mirror.

The reflection of light, for Isaac Newton has shewn, is not effected by the rays striking on the very parts of the bodies; but by some power of the body equally diffused throughout its whole surface, by which it acts upon the ray, attracting or impelling it without any immediate contact.

This power he shews to be the fame, by which, in other circumstances, the rays are refracted; and by which they are at first emitted from the lucid body. See Refraction.

The arguments he produces to prove this are as follow:

1. Because the surfaces of polished glafs, which to the eye appear smooth, are yet, in reality, very rugged and uneven (polishing being nothing but the grating, serrating, and breaking off the coarser protuberances, by means of sand, glafs, putty, tripolli). If the rays of light, therefore, were reflacted by striking on the solid parts of the glafs, the reflections would never be so accurate as we find they are, but the rays would even be as much scattered by the most polished glafs, as by the roughest. It remains, therefore, a problem how glafs, polished by fretting substances, can reflect light so regularly as it does; which problem is scarcely otherwise to be solved, than by saying, that the reflection of a ray is reflected, not by a single point of the
REFLECTION.

reflecting body, but by fame power of the whole body, evenly diffused all over its surface, and by which it acts on a ray without immediate contact; for that the parts of bodies do act upon light at a distance, is already shewn under the articles REFLECTION and LIGHT.

2. If the colours, separated by a prism placed at the entrance of a beam of light into a darkened room, be successively cast on a second prism placed at a greater distance from the former, in such manner as that they all fall alike, or with an equal obliquity, upon it; the second prism may be so inclined to the incident rays, that those which are of a blue colour shall be all reflected by it; and yet those of a red colour pretty copiously transmitted. Now, if the reflection were caused by the parts of the air or glasses, we would ask, why, at the same obliquity of incidence, the blue should wholly impinge on those parts so as to be all reflected; and yet, the red find pores enough to be, in a great measure, transmitted.

3. Where two glasses touch one another, there is no sensible reflection; and yet we see no reason why the rays should not impinge on the parts of the glasses, as much when contiguous to other glasses, as when contiguous to air.

4. When the top of a water bubble, by the continual fubliming and exhaling of the water, grows very thin, there is such a little, and almost inensible quantity of light reflected from it, that it appears intensely black; whereas round about that black spot, where the water is thicker, the reflection is so strong, as to make the water seem very white. Nor is it only at the leaf thicknefs of thin plates or bubbles, that there is no manifelt reflection, but at many other thicknefses, gradually greater and greater. For, in one of our author's observations, the rays of the fame colour were, by turns, transmitted at one thicknefs, and reflected at another thicknefs, for an intermediate number of fucceffions: and yet, in the superficies of the thinned body, where it is of one thicknefs, there are as many other parts for rays to impinge on, as where it is of any other thicknefs.

5. If the red and blue rays, separated by a prism, fall successively on a thin plate of any pellucid matter, whose thicknefs increases in continual proportion, (such as a plate of air between two glases, the one plane, and the other a little convex,) the fame plate will, in the fame part, reflect all the rays of one colour, and transmit all those of the other; but, in different parts, will reflect the rays of one and the fame colour at one thicknefs, and transmit them at another; and thus alternately, and in infinitum. Now, it can never be imagined that at one place the rays, which, for instance, exhibit a blue colour, should happen to strike on the solid parts, and those which exhibit a red, to hit on the void parts of the body; and at another place, where the body is either a little thicker, or a little thinner, that, on the contrary, the blue should hit on the pores, and the red upon the solid parts.

6. In the paffage of light out of glases into air, there is a reflection as strong as in its paffage out of air into glases, or rather a little stronger, and by many degrees stronger than in its paffage out of glases into water. Now, it seems improbable, that air should have more reflecting parts than water or glases; but if that should be suppos'd, yet it will avail nothing; for the reflection is as strong, or stronger, when the air is drawn from the glases by the air-pump, as when it is adjacent to it. If any should here object, on Descartes's hypothefs, that, though the air be drawn away, there is a subtle matter remaining to supply its place, which, being of a denser kind, is better fitted for the reflection of light than any other body; besides that we have elsewhere shewn such subtle matter to be fétitious, and that, suppos-

ing its exifience, and its reflecting power, no light could ever have been propagated, but must have been all reflected back to the lucid body, immediately after it was first emitted, the following experiment does evidently convict it of fality.

7. If light, in its paffage out of glases into air, strike more obliquely than at an angle of forty or forty-one degrees, it is then wholly reflected: if less obliquely, it is in great measure transmitted. Now, it is not to be imagined, that light at one degree of obliquity should meet with pores enough in the air to transmit the greater part of it, and at another degree should meet with nothing but parts to reflect it wholly; especially confidering, that, in its paffage out of air into glases, how oblique ever be its incidence, it finds pores enough in the glases to transmit a great part of it. If any fuppofe, that it is not reflected by the air, but by the utmost superficial parts of the glases, there is still the fame difficulty: besides, that such a fuppofition is unintelligible, and will also appear to be falfe, by applying water behind some part of the glases, instead of air; for in a convenient obliquity of the rays, fuppofe of forty-five or forty-fix degrees, at which they are all reflected, where the air is adjacent to the glases, they shall be in great measure transmitted where the water is adjacent to it; which argues, that their reflection or tranfmutation depends on the conftitution of the air and water behind the glases, and not on the ftriking of the rays upon the parts of the glases, the rays not being reflected until they have reached the last part of the surface, and have begun to go out. For if, in going out, they fall upon a surface of oil and water, they proceed, the attraction of the glases being balanced by an equal force the contrary way, and prevented from having its effect by the attraction of the liquor adhering to it: but if the rays, in paffing out of this last surface, fall into a vacuum, which has no attraction, or into air, which has but little, not enough to counterbalance the effect of the glases in this cafe, the attraction of the glases draws them back, and reflects them.

This will appear still more evident by laying two glases prisms, or the object-glases of two telescoes, the one plane, and the other a little convex, upon each other, fo as they may neither touch, nor yet be too far apart; for that light which falls on the hinder surface of the firft glases, where the glases are not above one inch apart, will be transmitted through the surface, and through the air or vacuum between the glases, and will pass into the second glases; but if the second glases be taken away, then the light paffing out of the second surface of the firft glases into the air or vacuum, will not proceed, but will return into the firft glases, and be reflected.

Whence it follows, that the rays are drawn back again by some force in the firft glases, there being nothing else to occasion their return. And hence too it follows, that the reflection is not effected by means of any subtle matter contiguous to the hinder surface, according to the principles of Descartes; since that matter ought to reflect them when the glases were nearly contiguous, as well as when the second glases is quite removed.

Lastly, if it be asked, how some of the rays come to be reflected, and others transmitted; and why they are not all alike reflected, supposing the reflection owing to the action of the whole surface? the fame great author shews, that there are, both in the rays of light, and in the bodies themselves, certain vibrations (or some such property) impressed on the rays, by the action either of the luminary that emits them, or of the bodies that reflect them: by means of which it happens that those rays, in that part of their vibration which
REFLECTION.

which conspires with the motion of the parts of the body, enter the body, are refracted and transmitted; but those in a contrary part of their vibration are reflected.

Add, that every ray of light, in its passage through any refracting surface, is put into a certain transient constitution or state, which, in the progress of the ray, returns at equal intervals, and disposes the ray, at each return, to be easily transmitted through the next refracting surface; and between each return, to be easily reflected by it.

These alternate dispositions, which Sir Isaac Newton calls fit of easy reflection, and of easy transmission, he accounts for by supposing, that as they are occasioned by the vibrations of a subtile fluid, in which the ray passes, which happening to move faster than the rays, when a ray is in that part of the vibration which conspires with its motion, it passes through; but when in the contrary part of the vibration, it is beat back again: whence every ray is successively disposed to be easily reflected, or easily transmitted, by every vibration which overtakes it.

He also thought that these vibrations might be excited by the mutual action and re-action of light, of bodies and of this medium, at the instant of reflection or refraction; so that, in fact, he supposes two causes of this disposition to be reflected or transmitted, when rays of light arrive at any new surface. One of them is the regular vibration of the ethereal medium, affecting them through the whole of their progress from the luminous body; and the other the tremulous motion, or irregular vibration of the same medium at the surfaces of bodies, occasioned by the action and re-action between light and them: for this last cause can hardly be supposed to affect the whole ethereal medium equally, and produce the regular return of these fits in every ray.

M. Boscovitch supposes with Newton, that the fits of reflection or transmission affect the rays themselves, in the whole of their passage from the luminous body, but that they arise from an alteration in their form, by means of the elasticity of their component parts, having been originally driven from the luminous body by a force which acted more strongly on the hinder parts than on the rest of the mafs, and thereby put them into a vibratory motion. He also supposes, that the intervals of the fits of easy reflection and transmission may be different in different rays, on the three following accounts. 1. The rays that are differently refrangible have different velocities, at least after reflection; so that, though the fits should return at equal intervals, it will affect different rays in different parts of their progress.

2. The unequal action between the points that compose the same particle of light may make a difference in their oscillations, at the time of changing their medium. And lastly, rays coming in different inclinations to the new surface, the internal motions of these points will be in different directions with respect to the surface, and consequently the whole mafs of the medium will act upon all the points differently.

Upon the whole, says Dr. Priestley, it is not more probable that the rays of light are transmitted from the sun, with an uniform disposition to be reflected or refracted, according to the circumstances of the bodies on which they impinge; and that the transmission of some of the rays under the same circumstances, apparently; while others that are reflected, is owing to the minute vibrations of the small parts of the surfaces of the mediums through which the rays pass; vibrations that are independent of action and re-action between the bodies and the particles of light at the time of their impinging, though probably excited by the action of preceding rays. As to the transmission or reflection of certain kinds of light only, producing colours in thin plates, the cause may be this; viz. that every particle of the medium has a great number of equal alternate intervals of attraction and repulsion, relatively to the particles of light; but that these intervals are of different magnitudes, according as the particles of light are of different colours. Now if the thickefs of any transparent medium in which the particles of matter are uniformly placed is such, that the attracting intervals of the extreme particles, as well as the repelling intervals, coincide with one another, i.e. attracting with attracting, and repelling with repelling, in regard to any one kind of rays, e.g. the red; by the united force of their extremes, (all the intermediate particles of the medium mutually destroying each other's effects,) those rays will be reflected. But where the plate is of an intermediate thickefs between this and the next thickefs, where the attracting intervals coincide, attracting with attracting, and repelling with repelling, the attracting intervals will coincide with the repelling ones, and the repelling ones with the attracting ones, and these mutually destroying one another's effects, those rays will pass on freely, and be transmitted. But as the intervals of attraction and repulsion are different for differently coloured rays, the thickefs of the plates at which these coincidences will or will not happen, in the differently coloured rays, will be different. So that it appears probable, says Dr. Priestley, in conformity to a doctrine first suggested to him by Mr. Michell, that the whole mystery of coloured plates depends upon the attractions and repulsions of the particles of the bodies that compose them, affecting different rays in a different manner, according to their thickefs.

Sir Isaac Newton concludes his account of the reflection of light with observing, that if light be reflected not by impinging on the solid parts of bodies, but by some other principle, it is probable that as many of its rays as impinge on the solid parts of bodies are not reflected, but filled and lost in the bodies. Otherwise, he says, we must suppose two kinds of reflection; for should all the rays be reflected which impinge on the internal parts of clear water or crystall, those substancies would rather have a cloudy colour than a clear transparency. To make bodies look black, it is necessary that many rays be stopped, retained, and lost in them; and it does not seem probable, that any rays can be stopped and filled in them, which do not impinge on their parts: and hence, he says, we may understand, that bodies are much more rare and porous than is commonly believed. However, M. Bouguer disputes the fact of light being filled or lost by impinging on the solid parts of bodies. See ABSORBING.

For other facts and observations relating to the subject of this article, see LIGHT. See also RAYS OF LIGHT, and RAYS OF HEAT.

REFLECTION, in Optics, is the return of a ray of light from the polished surface of a speculum or mirror, as driven thence by some power refiding in it.

The ray, thus returned, is called a refulx, or reflected ray, or a ray of reflection; and the point of the speculum, whence the return commences, is called the point of reflection.

Thus the ray A B (Plate I. Optics, fig. 3,) proceeding from the radiant A, and striking on the point of the speculum B, being returned thence to C, B C represents the reflected ray, and B the point of reflection; in respect of which A B represents the incident ray, or ray of incidence, and B the point of incidence.

Again, a line CG drawn from any point, as C, of the reflected
REFLECTION.

Reflected ray BC, perpendicular to the speculum, is called the \textit{catetus of reflection}, or \textit{catetus of the eye}: as a line AF, drawn from the radiant perpendicular to the speculum is called the incidence.

Of the two angles which the reflected ray BC makes with the mirror, the smallest, CBE, is called the \textit{angle of reflection}: as of the two angles the incident ray makes with the speculum, the smallest, ABD, is called the \textit{angle of incidence}.

If the mirror be either concave or convex, the smallest angles the ray makes with the tangent to the point of reflection and incidence, are the angles of reflection and incidence.

The angle CBE, which the reflected ray makes with a perpendicular to the point of reflection, is called the inclination of the reflected ray: as the angle ABD is called the inclination of the incident ray.

\textbf{Reflection, general laws of.—1. If a ray of light be reflected from a speculum of any form, the angle of incidence is ever equal to the angle of reflection.} This law obtains in perfections of all kinds of bodies; and consequently must do so in those of light. See \textit{Laws of Percussion}; see also \textit{Angle}.

It might therefore be here assumed as an axiom; but it is of that importance, and its demonstration so beautiful, that we cannot omit it. Suppose, then, DC (Plate XVII. Optics, fig. 14.) an incident ray, propagated from the radiant D; here, though the motion of the ray be simple, yet its determination in the line DC, being oblique with respect to the oblique, is really compounded of two determinations: the one along DE, the other along DG.

The force along DC, therefore, is equal to the two forces along DG and DH. But the oblique GF only opposes one of the determinations; viz., that along DG (for it cannot oppose a determination parallel to itself, as DE): therefore, only the force along DG will be lost by the stroke, that along DH or GC remaining entire. But a body perfectly elastic (such as we suppose the ray of light) will recover by its elactity the force it lost by the shock.

The ray, therefore, will recover the force DG or CH; thus, retaining both its forces, and both its former determinations HC and CF, after percussion, it will be impelled along CF and CH by the same forces as before along DH and DG. By its compound motion, therefore, it will describe the right line CE, and that in the same time as DC; and HE and DH will be equal, as being described by the same force. Now, the two triangles DCH and CFE are equal, and consequently their similar angles are equal. Since then HCA = HCF; DCA, the angle of incidence, is equal to ECF, the angle of reflection. Q. E. D.

This law is confirmed in light by an easy experiment.

For a ray of the sun falling on a mirror, in a dark room, through a little hole, you will have the pleasure to see it rebound, so as to make the angle of reflection equal to that of incidence. See \textit{Camera Obscura}.

The same may be shown by various other ways: thus, e.g., placing a semicircle FG, (Plate I. Optics, fig. 3.) on a mirror DE, its centre on B, and its limb perpendicular to the speculum; and assigning equal arcs, FA and GC, place an object in A, and the eye in C: then will the object be seen by a ray reflected from the point B. And if B be covered, the object will cease to be seen.

For the conclusions drawn from this general doctrine of reflection, see the doctrine of Mirrors, &c.

\textbf{II. Each point of a speculum reflects rays falling on it, from each part of an object. See the doctrine of Mirrors, &c.}

\textbf{III. If the eye C, and the radiant point A, change places, the point will continue to radiate upon the eye, in the same curve or path as before.}

For if the object be removed from A to C, it will still radiate on its former point of reflection, B; but there can be but one right line drawn between the two points G and D; and the rays are right lines. Therefore, that which was before the ray of reflection, will now be the ray of incidence; and since it will be reflected under the same angle as that at which it fell, that which was before the ray of incidence, will now be the ray of reflection. So that the object removed to C, will radiate on the eye placed in A, by the right lines CB and BA. Q. E. D.

Hence, an object is seen by the reflected ray AB, with the eye placed in A, the same as if the eye were in C, and the object in A.

The truth of this theorem is so easily confirmed by experiment, that fome, with Euclid, assume it as a principle, and demonstrate the great law of reflection from it. Thus: suppose the angle of incidence a little greater than the angle of reflection, then will the angle AFB be greater than CBE. Wherefore, changing the places of the eye and the object, the angle CBE will become the angle of incidence; and therefore CBE greater than AFB by the supposition. So that the same angle AFB will be both greater and smaller than the other, CBE; which being absurd, AFB cannot be greater than CBE. The same absurdity will follow, if you suppose the angle of incidence less than the angle of reflection. Since then the angle of incidence can neither be greater nor less than that of reflection, it must be equal to it.

\textbf{IV. The plane of reflection, that is, the plane in which the incident and reflected rays, and also the angles of incidence and of reflection, are found, is perpendicular to the surface of the speculum; and in spherical specula, it passes through the centre.}

Hence the cathetus, both of incidence and reflection, is in the plane of reflection.

That the plane of reflection is perpendicular to the speculum, is affirmed by Euclid, Alhazen, and others, as a principle, without any demonstration; as being evident from all observation and experiment.

\textbf{V. The image of an object seen in a mirror is in the cathetus of incidence.} This the ancients assumed as a principle; and hence, since the image is certainly in the reflected ray, they inferred, it must appear in the point of concourse of the reflected ray, with the cathetus of incidence; which indeed holds universally in plane and spherical mirrors; and also effedi in concave ones, a few cafes only excepted, as is shewn by Kepler.

For the particular laws of reflection, arising from the circumstances of the several kinds of specula, or mirrors, plane, concave, convex, &c. see them laid down under the article \textit{Mirror}.

\textbf{Reflection, Caustic by. See Caustic Curve.}

\textbf{Reflection of Heat. See Heat, and Rays of Heat.}

\textbf{Reflection of Cold. See Cold.}

\textbf{Reflection of Sound. See Sound.}

\textbf{Reflection of the Moon.} is a term used by some authors for what we otherwise call her \textit{variation}, being the third inequality in her motion, by which her true place out of the quadratures differs from her place twice equated. See \textit{Moon and Variation.}

Reflection is also used, in the Copernican system, for the distance of the pole from the horizon of the disk, which
which is the same thing as the sun’s declination in the Ptolemaic system.

Reflection is also used figuratively for an operation of the mind, by which, turning as it were back upon itself, it makes itself, and its own operation, its object; and considers or contemplates the manner, order, and law, which it observes in perceiving, reasoning, willing, judging, doubting, believing, &c. and frames itself new ideas of the relations discovered in them.

Reflector. See Curve Reflected.

Reflector for Light-houses. A combination of a number of square plane glass mirrors, resembling those with which Archimedes is said to have burnt the Roman fleet at the siege of Syracuse. (See Burning-Glafs.) Each of these mirrors is about an inch square; and they are all arranged close to each other in the concave of a parabolic segment formed of fluecco, which has been found to answer the purpose best. The idea of thus illuminating light-houses, instead of using coal-fires, in this country, without any previous knowledge of a similar method practiced in France, was first suggested by Mr. Ezekiel Walker, of Lynn Regis, who made, and fixed up reflectors under his direction, in a light-house on the coast of Norfolk, in the year 1779. Accordingly, in the year 1787, at the request of the trustees appointed by act of parliament for erecting four light-houses in the northern parts of Great Britain, he instructed Mr. Thomas Smith, tin-plate worker, of Edinburgh, to whom the original invention is erroneously ascribed in the supplement to the Encyclopaedia Britannica, in this mode of constructing light-houses. His parabolic moulds are from three to five or six feet in diameter; and in the centre or apex of each is placed a long shallow lamp of tin-plate, filled with whale-oil. In each lamp are fixed cotton-wicks, almost contiguous to one another, so disposed as to burn without trimming for six hours. The light of these is reflected from each mirror spread over the concave surface, and is thus multiplied, as it were, by the number of mirrors. The fluecco moulding is covered on the back with tin-plate, from which a tube, immediately over the lamp, proceeds to the roof of the light-room, and serves as a funnel, through which the fume escapes without tulling the faces of the mirrors. The light room is a cupola or lantern of from eight to twelve sides, composed entirely of glafs, fixed in cast iron frames or sashes, and roofed with copper. On circular branches affixed round the inside of this lantern, at about 18 inches from the glafs frames, are placed the reflectors with their lamps, so that the concave surfaces of two or three of the reflectors from every point of the compass, and throw a blaze of light in all directions. In the roof, immediately over the centre of the room, is a hole, through which pass all the funnels already mentioned, and which serves likewise to admit freh air to the lamps. This light-room is firmly fixed on the top of a round tower, so as to be immovable by the weather; and the number of the reflectors, and the height of the tower, are les or greater according as it is intended that the light should be seen at a les or a greater distance. Experience, it is said, has obviated several objections to which light-houses of this kind were thought to be liable; and it has been found that light-houses, with lamps and reflectors, are, in every point of view, preferable to those with fires burning in the air. They are supported at a much les expense; their light is more brilliant, and seen at a greater distance, whilst it can never be obscured by smoke, or beaten down, on the lee-side, by a violent gull of wind; and they may be so variously placed, that one light-house cannot be mistaken for another. Besides, the lamps do not need trimming to often open fires require fuel, and the man who attends them is never exposed either to cold or wet in the performance of his duty, so that they are les likely to be neglected in stormy weather than those with open fires.

It has been proposed to make the concave surface of the parabolical speculum of metal, instead of covering it over with a number of plain glafs mirrors; or to diminish the size of each mirror, if it be thought best to retain them instead of introducing the speculum. To this proposed alteration it has been objected, that the brightest metal does not reflect such a quantity of light as well foliated clear glafs; and by diminishing the size of the mirrors, the number of joinings would be increased, in each of which some light is lost, not merely in the beam, but from its being almost impossible to foliate glafs perfectly at its edge.

Reflection, reflect, in Painting, is understood of those places in a picture which are supposed to be illuminated by a light reflected from some other body represented in the same piece.

Or, reflectes may be defined those places which, besides the general light that illumines the whole piece, receive some particular light from their situation with respect to some more illuminated polished body, that reflects part of the light it receives upon them.

Reflectes are scarcely sensible, except in the shadowed parts. The management of the reflectes requires great accuracy and skill. All reflected light is supposed to carry with it part of the colour of the body which reflects it; so that those places which receive this light, must have their colour mixed or tinged with that colour. But the same place may receive reflectes from different objects, differently coloured, and those again receive reflectes from others. The painter, therefore, must have a view to every circumstance of the colour, light, and position of each figure; he must consider what effect each has on others, and pursue nature through all the variety of mixtures. See Clair-obscure, and Light.

Reflex vision, or Reflected vision, is that performed by means of rays reflected from the polished surfaces of objects to the eye.

Reflex vision is the subject of catoptics. Under reflex vision come all the phenomena of specula or mirrors of all kinds.

Reflexibility of the Rays of Light, is that property by which they are disposed to be reflected. See Reflection.

Or, it is their disposition to be turned back into the same medium, from any other medium on whole surface they fall; hence those rays are said to be more or less reflexible, which are returned back more or less easily under the same incidence.

Thus, if light pafs out of glafs into air, and by being inclined more and more to the common surface of the glafs and air, begins at length to be totally reflected by that surface, those parts of rays which at like incidences are reflected most copiously, or the rays which, by being inclined, begin soonest to be totally reflected, are the most reflexible.

That rays of light are of different colours, and endowed with different degrees of reflexibility, was first discovered by Sir Isaac Newton; and is shewn by the following experiment.

Applying a prism D F E (Plate XVII. Optics, fig. 15.), whose angles are each 45°, to the aperture C of a darkened room, in such manner that the light is reflected from the bafe in G; the violet rays are seen first reflected into H G; the other rays continuing still refracted in I K. After the violet the blue are all refracted, the green, &c. 4 D (See
REF

(See Colour.) Hence it appears, that the differently coloured rays differ in degree of refraction.

From the other experiments it appears, that those rays which are most refrangible, are also most refrangible. See Refrangibility.

REFLEXION. See Reflection.

REFLEXITY, a term employed by Mr. Brougham to denote a property of light, which causes the different rays to be acted upon by bodies, and to begin to be refracted, refected, inflected, and deflected, at different distances. This property observes the same law with the other optical properties of light; the red ray having most refraction, and the violet the least. (See Phil. Trans. for 1797, p. 360.) Mr. Brougham has expressed this property by the three words, "refrangity," "reflexity," and "flexity," but the power being the same, if such a property exist, different names seem to be unnecessary.

REFLUX of the Sea, the ebbing of the water; or its return from the shore. It is thus called, as being the opposite motion to the flood, or flux. See Tide.

REFORM, a re-establishment, or revival of former neglected discipline; or a correction of some reigning abuses in it.

The term is much used in a monastic sense, for the reducing an order or congregation of religious to the ancient severity of the rule from which it had gradually swerved; or even for the improving on the ancient rule and institution itself, and voluntarily making it more severe.

In this sense the order of St. Benedict is said to be only a reform of that of St. Benedict.

To Reform, in a Military Sense, is, after some evacuation or manoeuvre, to bring a line to its natural order, by aligning it on some given point. See Battalion.

To Reform, is also to reduce a company, regiment, or other body of men, either by disbanded the whole, or only breaking a part, and retaining the rest; or sometimes by incorporating them with other regiments. Hence,

REFORMADO, or Reformed officer, one whole troop or company is suppled in a reform, whilst he is continued either in whole or half-pay, doing duty in the regiment. A reformed captain of foot follows the company, and affilts the flanding officer as a second; but he still maintains his degree and precedence.

REFORMATION, Reformatio, the act of reforming, or correcting an error, or abuse, in religion, discipline, or the like.

The reformation of religion, called, by way of eminence, the Reformation, was begun by the electors of Saxony, at the solicitation of Luther, about the beginning of the sixteenth century. See Luther and Lutheranism.

There were many circumstances which concurred at this time to bring about that happy reformation in religion, which rescued one part of Europe from the papal yoke, mitigated its rigour in the other, and produced a revolution in the sentiments of mankind, the greatest as well as the most beneficial that has happened since the publication of Christianity. How far the sale of indulgences, published by Leo X, contributed to this event, we have already shown under the article Luther. We shall here observe, that the fame corruptions in the church of Rome which Luther condemned, had been attacked long before his appearance, and the fame opinions which he propagated had been published in different places, and supported by the fame arguments. Walchus in the 12th century, Wickliffe in the 14th, and Hus in the 15th, had inveighed against the errors of Popery with great boldness, and confuted them with more ingenuity and learning than could have been expected in those illiterate ages in which they flourished. But all these premature attempts towards a reformation proved abortive. Many powerful caufes contributed to facilitate Luther's progress, which either did not exist, or did not operate with full force in their days: the principal of these we shall here enumerate. The long and scandalous fehism which divided the church, during the latter part of the 14th, and the beginning of the 15th centuries, had a great effect in diminishing the veneration with which the world had been accustomed to view the papal dignity. The proceedings of the councils of Constance and Bafel spread this disrespect for the Romish see still wider, and by their bold exertion of authority in depopulating and electing popes, taught the world that there was in the church a jurisdiction superior even to the papal power, which they had long beloved to be supreme. The wound given on that occasion to the papal authority was severely healed, when the pontificates of Alexander VI. and Julius II. both able princes, but detestable ecclesiastics, raised new scandal in Chriftendom. Besides, many of the dignified clergy, secular as well as regular, neglected the duties of their office, and indulged themselves, without reserve, in all the vices to which great wealth and idleness naturally give birth; and gross ignorance and low debauchery rendered the inferior clergy as contemptible as the others were odious. So that we find, long before the 15th century, that many authors of reputation gave such description of the difolute morals of the clergy, as seems almost incredible in the present age. The scandal of these crimes, which very generally prevailed, was greatly increased by the facility with which such as committed them obtained pardon. The exorbitant wealth of the church, the vast personal immunities of ecclesiastics, and their encroachments on the jurisdiction of the laymen, and their various devices to secure their usurpations, created much dissatisfaction among the people, and difposed them to pay particular attention to the invectives of Luther.

Besides these caufes of his rapid progress, we may also reckon the invention of the art of printing, about half a century before his time, the revival of learning at the same period, and the bold spirit of inquiry which it excited in Europe; so that many were prepared to embrace his doctrines, who did not really with success to his undertaking. In the writings of Reuchlin, Hutten, and the other revivers of learning in Germany, the corruptions of the church of Rome are cursed with an acrimony of style little inferior to that of Luther himself. The raillery and oblique cenfures of Erasms in particular, upon the errors of the church, as well as upon the ignorance and vices of the clergy, prepared the way for Luther's invectives and more direct attacks. To all which we may add, that the theological doctrines of Popery were so repugnant to the spirit of Chriftianity, and so detestable of any foundation in reason, in the word of God, or in the practice of the church, that this circumstance combined in favouring the progress of Luther's opinions, and in weakening the resistance of his adversaries.

The rise of the reformation in Switzerland was at least as early as in Germany; for Ulric Zuingle had, in the year 1516, begun to explain the scriptures to the people, and to confufe, though with great prudence and moderation, the errors of a corrupt church. He had very noble and extensive ideas of a general reformation, at the time when Luther retained almost the whole system of Popery, indulgences excepted; and he had actually called in question the authority and supremacy of the pope, before the name of Luther was known in that country. In the year 1524, Nuremberg, Frankfort, Hamburg, and several other cities in Germany, of the first rank, openly embraced the reformed religion, and by the authority of their magistrates abolished the
the mafs, and the other superstitious rites of Popery. The elector of Brandenburgh, Saxony, the marquis of the land-grave of Helft, the dukes of Braunwick and Lunenburgh, and prince of Anhalt, became avowed patrons of Luther's opinions, and countenanced the preaching of them among their subjects. The reformers derived great advantage from the transactiouns of the diet at Nuremberg, which presented to the pope a catalogue of a hundred grievances, which the empire imputed to the iniquitous dominion of the papal see. The progress of the reformation in Germany was likewise promoted by the proceedings of the diet held at Spire in the years 1526 and 1529. See Luther and Protestants.

During these transactiouns in Germany, the dawn of truth arofe upon other nations. The light of the reformation spread itself far and wide; and almost all the European states welcomed its salutary beams, and exalted in the prospect of an approaching deliverance from the yoke of superstition and spiritual delirium. Some of the most considerable provinces of Europe had already broke their chains, and openly withdrawn themselves from the discipline of Rome and the jurisdicition of its pontiff. The reformed religion was propagated in Sweden, soon after Luther's rupture with Rome, by Olaus Petri, one of his disciples, who was countenanced and encouraged by the valiant and public-spirited prince Guftavus Vafa Ericfon, to whom firmness and magnanimity it was owing, that from the year 1527 the papal empire in Sweden was entirely overturned, and Guftavus declared head of the church. The light of the reformation was also received in Denmark so early as the year 1521, in consequence of the ardent desire discovered by Christian or Chriftienn II., for purposes of mere ambition, of having his disciples instructed in the doctrines of Luther. His successor Frederic, duke of Holstein and Silefia, contributed greatly to the progress of the reformation, by his successful attempts in favour of religious liberty, at the assembly of states that was held at Odense, in the year 1527, when he procured the publication of the famous edict which declared every subject of Denmark free, either to adhere to the tenets of the church of Rome, or to embrace the doctrine of Luther; that no perfon should be molest'd on account of his religion; that a royal protection should be granted to the Lutherans; and that ecclesiastics of every order should be allowed to marry. But the honour of accomplishing this glorious work was referved for Chriftienn III., a prince equally distinguished by his piety and prudence. The religious doctrine, discipline, and worship of this kingdom, were fettled according to a plan laid down by Bugenhagi. And the assembly of the states at Odense, in 1539, gave a solemn fæcution to all thefe transactiouns, and thus the work of reformation was brought to perfection in Denmark.

In France, the auspicious patronage of Margaret, queen of Navarre, sister to Francis I., encouraged several pious and learned men, whose religious sentiments were the fame with her own, to propagate the principles of the reformation, and even to erect several Protestant churches in that kingdom. It appears, that, fo early as the year 1523, there were many, and even persons of rank, and some of the episcopal order, who had conceived the utmost averion both against the doctrine and tyranny of Rome. But the wavering and inconsistent conduct of Francis I. rendered the situation of the Protestants in this country always precarious, often distrest. Upon the whole, we may observe, that before the diet of Augsburg, the doctrine of Luther had made considerable, though perhaps a secret, progress in Spain, Hungary, Bohemia, Britain, Poland, and the Netherlands, and had, in all these countries, many friends, of whom several repaired to Wittemberg to improve their knowledge, and enlarge their views under such an eminent master. At this diet, held in 1530, the Augsburg or Auguflina confession was presented to the emperor Charles V. and after many debates between the friends of liberty and the votaries of Rome, the latter prevailed; and the diet, in compliance with the opinion and remonfiances of Campeggio, the papal nuncio, issued a decree, condemning most of the peculiar tenets held by the Protestants; forbidding any perfon to protect or tolerate those who taught them; enjoining a strict observance of the eftablished rites; and prohibiting any farther innovation, under severe penalties. Those who refused to obey this decree were declared incapable of acting as judges, or of appearing as parties in the imperial chamber, the supreme court of judicature in the empire. The Protestants, alarmed at the severity of the decree, assembled at Smalcald, and concluded a league of mutual defence against all aggressors, by which they formed the Protestant states of the empire into one regular body; and they resolved to apply to the kings of England, France, and Denmark, to implore them to affit and patronize this new confedcracy. After various negotiations between the emperor and the Protestant princes, terms of pacification were agreed upon at Nuremberg, and ratified solemnly in the diet of Ratisbon, in the year 1532. In this treaty it was stipulated, that universal peace be established in Germany, until the meeting of a general council, the convocation of which, within six months, the emperor fhall endeavour to procure; that no perfon be molest'd on account of religion; that a stop be put to all proceffes begun by the imperial chamber against Protestants; and the sentences already paffed to their detriment be declared void. On their part, the Protestants engaged to affit the emperor with all their forces in refifting the invasion of the Turks. Thus the Protestants, by their firmness, unanimity, and dexterity in availing themselves of the emperor's situation, obtained terms which amounted almost to a toleration of their religion. But neither the emperor nor the pope were disposed to abide by the unbiased fentence of a general council, assembled, as the Protestants wished, within the limit of the empire, but determined to decide their religious debates by the force of arms. After many evasions and delays, it was propofed, in the year 1545, to assemble a council at Trent, which was vigorously opposed by the Protestants. The emperor and the pope had mutually agreed to delivcr all who should dare to oppose this council. The meeting of that assembly was to serve as a signal for their taking arms; and accordingly its deliberations were fearcely begun, in the year 1546, when the Protestants perceived undoubted marks of a formidable union to overwhelm and cruth them by one blow. The fathers, assembled in the council of Trent, promulgated

4 D 2
their decrees; and the Protestant princes in the diet of 
Ratisbon protected against their authority; and were, in confu-
quence of this, proferred by the emperor, who raised an
army to reduce them to obedience. Thus commenced the
war of Smalcald, which was prosecuted with various suc-
cesses on both sides, till, in the year 1552, Charles was surprized
at Infrac by Maurice of Saxony, and was contractured to
conclude at Passau the famous treaty of pacification, (which 
fee,) with the Protestants, which is considered by those of
Germany as the basis of their religious liberty; and to pro-
mise in six months to assemble a diet, in which all the tumults
and disaffections, that had been occasioned by a variety of sen-
timents in religious matters, should be entirely removed.
This diet, though not assembled at the stipulated time, met,
however, at Augsburg, in the year 1555, and terminated 
these deplorable scenes of bloodshed, delusion, and discord,
that had so long afflicted both church and state by that reli-
gious peace, as it is commonly called, which secured to the
Protestants the free exercise of their religion, and esta-
lished this inestimable liberty upon the firme foundations.
For, after various debates, the following memorable acts 
were passed; that the Protestants who followed the con-
fection of Augsburg, should for the future be considered as
entirely exempted from the jurisdiction of the Roman pon-
tiff, and from the authority and superintendance of the 
bishops; that they were left at perfect liberty to enact laws
for themselves, relating to their religious sentiments, dis-
cipline, and worship; that all the inhabitants of the German
empire should be allowed to judge for themselves in religious
matters, and to join themselves to that church whose doc-
trine and worship they thought the purest and most consonant
to the spirit of Christianity; and that all those, who should
injure or persecute any person under religious pretexts, and
on account of their opinions, should be declared, and pro-
ceed against, as public enemies of the empire, invaders of
its liberty, and disturbers of its peace.

In the year 1533, Henry VIII. king of England, who,
in the beginning of these troubles, had opposed the doctrine
and views of Luther with the utmost vehemence, partly be-
cause he had spoken with contempt of Thomas Aquinas,
the king's favourite author, having sued for a divorce from
Catharine of Arragon, his brother's widow, at the court of
Rome, for almost six years, during which period Clement VII.
negotiated, promised, retraeted, and concluded nothing, de-
termined to apply to another tribunal for that decree which
he had unsuccessfully solicited at Rome. Cranmer, arch-
bishop of Canterbury, by a sentence founded on the author-
ity of universities, doctors, and abbies, who had been consu-
flated with respect to the point, annulled the king's mar-
riage with Catharine; and Anne Boleyn, whose charms had
captivated the king, was acknowledged as queen of Eng-
land. Clement, apprehensive lest England would revolt from
the holy see, determined to give Henry such satisfaction as
might disconcert him within the bosom of the church. But
the violence of the cardinals precipitated him, in 1534, to
issue a bull recanting Cranmer's sentence, confirming Henry's
marriage with Catharine, and declaring him excommunicated.
If, within a time specified, he did not abandon the wife he
had taken, and return to her whom he had deserted, En-
angered at this unexpected decree, Henry kept no longer any
inferences with the court of Rome; his subjects feconded his
rebellion; an act of parliament was passed, abolishing the
papal power and jurisdiction in England; and another the
king was declared supreme head of the church, and all the
authority of which the popes were deprived was vested in
him; the monasteries, (which fee,) were appreashed, and their
revenues applied to other purposes.

The people had been gradually prepared for this great
innovation. Each succeeding feccion of parliament had
made some retrenchment from the power and profits of the
Roman pontiff. Care had been taken, during fome years,
to teach the nation that a general council was much superior
to a pope. But now a bishop preached every Sunday at
Paul's Crofs, in order to inculcate the doctrine, that the
pope was intitled to no authority at all beyond his own
diocefe.

The laws pased during this feccion (1534) sufficiently
evince, that the king was determined not to surrender any
part of his aifumed prerogative. All payments made to the
apostolic chamber, all provisions, bulls, diffentions, were
abolished; monaftics were to be subject to the regulation and
government of the king alone; the law for punishing her-
eties was moderated: the ordinary was prohibited from im-
prisoning or trying any perfon upon thefeption alone, with- 
out pretence of by ten lawful witnefles: and it was declared
that to fpeak againft the pope's authority was no hereby:
bishops were to be appointed by a congé d'élire from the
 crown, or, in cafe of the dean and chapter's refufal, by
letters patent; and no reccourse was to be had to Rome for
palls, bulls, or provifions. Campeggio and Ghinucchi, two
Italians, were deprived of the bifhoprics of Salisbury and
Worcefter, which they had hitherto enjoyed: the law which
had been formerly made against paying annats, or first fruits,
but which had been left in the king's power to suspend or
enforce, was finally established: and a submiffion which was
exactcd two years before from the clergy, and which had been
obtained with great difficulty, received this feccion the 
fonation of parliament. In this submiffion, the clergy ac-
knowledged that convocations ought to be assembfed by the
king's authority oniy: they promised to enact no new canons
without his confent: and they agreed that he should appoint
32 commissioners, in order to examine the old canons, and
abrogate fuch as should be found prejudicial to his roya-
brerogative. An appeal was alo allowed from the bishop's
court to the king in chancery. But the moft important act
pased this feccion, was that which regulated the fuccelfion
to the crown: the marriage of the king with Catharine
was declared unlawful, void, and of no effect: the primates
fentence annulling it was ratified; and the marriage with
queen Anne was eftablished and confirmed. The crown was
appointed to defend to the issue of this marriage, and fail-
ing there, to the king's heirs for ever. An oath was like-
wise enjoined to be taken in favour of this order of fucces-
fion, under the penalty of imprisonment during the king's
pleasure, and forfeiture of goods and chattels: and all flnder
against the king, queen, or their issue, was subject to the
penalty of misprision of treason. Thle fewcrs acts, so con-
temptuous towards the pope, and so destructive of his au-
thority, were pased at the very time that Clement pronounced
his holy sentence against the king. The king found his
eccleratical subjects as compliant as the laity. The con-
voction ordered that the act against appeals to Rome, to-
gether with the king's appeal from the pope to a general
council, should be affixed to all the doors of all the churches
in the kingdom; and they voted that the bishop of Rome had,
by the laws of God, no more jurifdiition in England than
any other foreign bishop; and that the authority which he
and his predecessors had there exercised, was only by usurpa-
tion, and by the suflerence of English princes. The bishops
went fo far in their compliance, that they took out new
commiffions from the crown, in which all their spiritual
and episcopat authority was expressly affirmed to be derived ul-
timately from the civil magistrate, and to be entirely de-
pending on his good pleasure.

Henry,
Henry, however, with the caprice peculiar to his character, continued to defend the doctrines of the Romish church as fiercely as he attacked their jurisdiction. He alternately persecuted the Protestants for rejecting the former, and the Catholics for acknowledging the latter.

Nothing more forwarded the first progress of the reformers, than the offer which they made, of submitting all religious doctrines to private judgment, and the succeeding given every one to examine the principles formerly imposed upon them. And what can be more just and reasonable? yet and the multitude, says Mr. Hume, were totally unqualified for this undertaking, though they were highly pleased with it. They fancied that they were exercising their judgment, while they opposed to the prejudices of ancient authority more powerful prejudices of another kind. The novelty itself of the doctrines; the pleasure of an imaginary triumph in dispute; the fervent zeal of the reformed preachers; their patience, and even alacrity, in suffering persecution, death, and torments; a disgust at the restraints of the old religion; an indignation against the tyranny and interested spirit of the ecclesiastics:—these motives, says the same historian, whilst, as some may imagine, he is depreciating the principles of the reformation, were prevalent with the people; and by such considerations were men so generally induced, during that age, to throw off the religion of their ancestors. In proportion, says the same author, as the practice of submitting religion to private judgment was acceptable to the people, it appeared, in some respects, dangerous to the rights of sovereigns, and seemed to destroy that implicit obedience on which the authority of the civil magistrate is chiefly founded. When some Englishmen, such as Tindal, Joye, Conflantine, and others, retired to Antwerp, through fear of the exertion of the king’s authority, they employed themselves in writing English books against the corruptions of the church of Rome; against images, relics, and pilgrimages; and they excited the curiosity of men with regard to that question, which is the most important in theology, the terms of acceptance with the Supreme Being. These books, having been secretly conveyed to England, began to make converts everywhere; but it was a translation of the scriptures by Tindal that was esteemed the most dangerous to the established faith. Against Wolsey, a favourite minister of Henry VIII., it was one article of impeachment, that, by his connivance, he had encouraged the growth of heresy, and that he had protected and acquitted some notorious offenders. Wolsey was succeeded in the office of chancellor by Sir Thomas More, who, irritated by polemics, became so superstitiously attached to the ancient faith, that few inquisitors have been guilty of greater violence in their prosecution of heresy. Several persons were not only brought into the courts for heretical offences, such as teaching their children the Lord’s prayer in English, for reading the New Testament in that language, or for speaking against pilgrimages; and others were charged with the capital offences of harbouring perfecuted preachers, neglecting the acts of the church, and declining against the vices of the clergy. Some were tried, condemned, and committed to the flames. Notwithstanding the inconstant conduct of Henry, his subjects having been encouraged, by his example, to break some of their fetters, they were so impatient to shake off all that remained, that in the following reign, under his son Edward VI., with the general applause of the nation, a total separation was made from the church of Rome in articles of doctrine, as well as in matters of discipline and jurisdiction. (See Articles.) In 1553, his death retarded the progress of the reformation; and his sister Mary, who succeeded him, imposed anew the arbitrary laws and tyrannical yoke of Rome upon the people of England. But the execution of a great number of persons, who were burnt for the Protestant faith in the five years of her persecuting and bloody reign, so alienated the people from Popery, that queen Elizabeth, her sister, found it no hard matter to deliver her subjects from the bondage of Rome, and to establish that form of religious doctrine and ecclesiastical government, which still subsists in England.

The seed of the reformation were very early sown in Scotland, by several noblemen of that nation, who had resided in Germany during the religious disputes that divided the empire. The first and most eminent opposer of the Papal jurisdiction was John Knox, a disciple of Calvin, who set out from Geneva for Scotland in 1559, and in a little while prevailed with the great part of the Scotch nation entirely to abandon the superfluities of Rome, and to aim at nothing less than the total extirpation of Popery. In the following year, viz. 1560, the parliament ratified a confession of faith, agreeable to the new doctrines, and passing a statute against the mass, not only abolished it in all the churches, but enacted, that whoever, any where, either officiated in it, or was present at it, should be chastised, for the first offence, with confiscation of goods, and corporal punishment, at the discretion of the magistrate; for the second, with banishment; and for the third, with loss of life. A law was also voted for abolishing the Papal jurisdiction in Scotland; the Presbyterians form of discipline was settled, leaving only at first some shadow of authority to certain ecclesiastics, whom they called superintendents. From that period to the present times the form of doctrine, worship, and discipline, that had been established at Geneva by the ministry of Calvin, has been maintained in Scotland with invincible obduracy and zeal; and every attempt to introduce into that kingdom, the rites and government of the church of England, has proved impotent and unsuccessful.

See Presbyterians.

The cause of the reformation in Ireland underwent the same vicissitudes that had attended it in England. When Henry VIII., after the abolition of the Papal authority, was declared supreme head of the church of England, George Brown, a native of England, and a monk of the Auguflin order, whom that monarch had created, in the year 1535, archbishop of Dublin, began to act with the utmost vigour, in conformance of this change in the hierarchy. He purged the churches of his diocese from superfluities in all its forms, pulled down images, destroyed relics, abounded absurd and idolatrous rites, and, by the influence as well as authority he had in Ireland, caused the king’s supremacy to be acknowledged in that nation. Henry flewsoon after, that this supremacy was not a vain title; for he banished the monks out of that kingdom, confiscated their revenues, and destroyed their convents. In the reign of Edward VI. farther progress was made in the reformation, but the accession of Mary retarded it, in consequence of which Brown and other Protestant bishops were deprived of their dignities in the church. When Elizabeth ascended the throne, the Irish were again obliged to submit to the form of worship and discipline established in England.

The reformation had not been long established in Britain, when the Belgic provinces, united by a respectable confederacy which still subsists, withdrew from their spiritual allegiance to the Roman pontiff. The means which Philip II. of Spain used to obstruct the reformation, promoted it: the nobility formed themselves into an association, in the year 1566, and rout the people; who, under the heroic conduct of William of Nassau, prince of Orange, seconded by the succours of England and France, delivered this state from
from the Spanish vassals in consequence of which the reformed religion, as it was practised in Switzerland, was established in the United Provinces: and, at the same time, in universal experience proved to all the religious instruments were of a different nature, whether they retained the form of Rome, or submitted the reformation in another form, provided that here were no attacks against the authority of the government, or the tranquility of the public.

While Mr. Hume attributes the quick and surprising progress of the reformation in part to the late invention of printing, and quickness of learning, he denies that reason had any considerable share in opening men's eyes with regard to the impropriety of the Roman church. Alleging that philosophy has made such progress, at least not the long after the period of the reformation, and that no evidence occurs in which argument can ever be able to free the people from the erroneous kind of absurdities which characterize the every where seminar people: to which he adds, that the rapid advance of the Lutheran doctrine, and the violence with which it was endeavored, prove sufficiently that it owed not its success to reason and reflection. The art of printing, and the revival of learning, might, perhaps, have been favorable to this another manner. Even means of that are the tools of letters and the reasons, full of vehemence, declamation, and a moral eloquence, were propagated more quickly, and in greater numbers, than would have been the case with the same instruments and the same persons, were prepared for every country, and applied not to treat in any useful path, which was opened to them. And as copies of the Tempore, and other books, of the Christian church, became more common, men perceived the innovations which were introduced after the sixteenth century; and though argument and reasoning could not give conviction to rational men, as was supposed, it was not possible to make impression on those persons. And the ambitious would not agree to publish their principles, though ancient and prior to all other possible establishment in Europe, and matters of civil right, which men might desire, and approved till a future time, they could not tempt men to look to their primitive charter, which would not be lawful, they could not perceive it to be defective in truth and authority. Before, Luther and his followers, not satisfied with repeating the pretended discovery of the Roman church, and displaying the temporal inconveniences of that establishment, proceeded to treat the religion of his ancestors as incomparable, inexpressible, and admirable; fostered by law, which was held in the place of all precedents and prejudice. They denominated the pope antichrist, called him the Antichrist, and gave to Rome the appellation of Babylon; expeditions which, however applied, were to be found in tempore, and which were better calculated to operate on the multitude than the much field arguments. Exacted by custom and tradition, on the one hand, by force, and on the other, many of the reformers carried to the present external conceptions of the pope to the church of Rome, and it can be ascribed to the multiplied superstitions with which that command was loaded, so adopted as standard form of doctrine, which admitted of no exceptions, rites, or ceremonies, but placed all men in a mysterious species of service, in eternal vision, purgatory, and excommunication. The new sectaries, derived from this spirit, were inadmissible in the propagation of their doctrine, and let it distance all the anathemas and punishments with which the Roman pontiff endeavored to overwhelm them.

Thus, in terms which appear to us too disparaging, does our historian describe the origin and progress of the reformation; nor does he pay due respect to the principles on which it was founded, and to the character of the persons who were the principal agents in accomplishing it. We are ready to acknowledge, that the collateral circumstances above noted have rendered its advances more rapid and more extensive; but we cannot admit that it did not owe much of its success to reason and reflection. But whatever may be our opinion of the primary causes that produced it, its influence on the minds and manners of mankind, on the state of society in general, and on the interests of liberty, religion, and virtue, has been constantly and extensively beneficial. Luther had no sooner begun to attack the papal supremacy, than the claims, which had bound mankind for so many ages, was broken at once. The human mind, which had long continued in tame and passive, as if it had been taught to believe whatever was taught, and to bear whatever was imposed, was moved, rebelled at a hidden, and became inquisitive, ambitious, and disdainful of the yoke which it had hitherto submitted. The reformation, wherever it was received, insulted that bold and innovating spirit to which it owed its birth. Men who had the courage to overturn a system supported by every thing which our command respect or reverence, were not to be overawed by any authority, how great or venerable soever. After having been accustomed to consider themselves as judges of the most important doctrines in religion, to examine these freely, and to reject, without scruple, what appeared to them erroneous, it was natural for them to turn the same daring and inquisitive eye to government, and to think of reforming whatever disorder or imperfection were discovered there. As religious abuses had been reformed in several places, without the permission of the magistrates, it was an easy transition to attempt the redress of political grievances in the same manner. But though the spirit of innovation, that was excited and promoted by the reformation, might in some instances prove the occasion of turbulence and tumult, the good that eventually accrued from its operation far exceeded the partial and temporary evil that resulted from it. The prevalence of this spirit was so general, that it must have been excited by causes that were natural, and of powerful efficacy; and the consequences that flowed from them must have been of the same nature of which and interesting as the causes that produced them. The kingdoms of Denmark, Sweden, England, and Scotland, and almost one half of Germany, threw off their allegiance to the pope, abolished his jurisdiction within their territories, and gave the function of law to the powers of discipline and system of doctrine, which were not only independent of his power, but hostile to it. Nor was this spirit of innovation confined to those countries which openly revolted from the pope; it spread through all Europe, and broke out in every part of it with various degrees of violence. It penetrated early into France, and made so rapid progress, that the number of converts to the opinions of the reformers was so great, their zeal so excessive, and the abilities of their leaders so distinguished, that they soon ventured to contend for superiority with the established church, and were sometimes on the point of obtaining it. In all the provinces of Germany which continued to acknowledge the papal supremacy, as well as in the Low Countries, the Protestant doctrines were secretly taught, and had gained so many adherents, that they were ripe for revolt, and were restrained merely by the dread of their rulers from imitating the example of their neighbours, and asserting their independence; hence in Spain and Italy, symptoms of the same dispositions to shake off the yoke appeared. The pretensions of the pope to infallible knowledge and supreme power were treated by many persons of eminent learning and abilities with such vehemence, or impugned with
REF

with such vehemence, that the most vigilant attention of the civil magistrate, the highest strains of pontifical authority, and all the vigour of the inquisitorial jurisdiction, were requisite to check or extinguish it. The defection to so many opulent and powerful kingdoms from the papal see was a fatal blow to its grandeur and power, and produced a very considerable diminution of its revenues. It likewise obliged the Roman pontiffs to adopt a different system of conduct towards the nations which continued to recognize their jurisdiction, and to govern them by new maxims, and with a milder spirit. They became afraid of venturing upon any such exertion of their authority as might alarm or exasperate their subjects, and excite them to a new revolt. Hence it happens, that the popes, from the era of the reformation, have ruled rather by address and management than by authority. They have been obliged not only to accommodate themselves to the notions of their adherents, but to pay some regard to the prejudices of their enemies. In process of time, and before the convulsions which have lately agitated Europe, they sank almost to a level with the other princes of Italy; and hardly retain any shadow of the temporal power which they anciently possessed. Nevertheless, whilst the reformation has been fatal to the power of the popes, it has contributed to improve the church of Rome both in science and in morals. Many motives have arisen out of the reformation, and the existence of two rival churches, which have served to engage the Catholic clergy to apply themselves to the study of useful science, and to pay a direct attention to the manners of their clergy. In those countries where the members of the two churches have mingled freely with each other, or have carried on any considerable intercourse, either commercial or literary, an extraordinary alteration in the ideas, as well as in the morals, of the Papish ecclesiastics is manifest. The beneficial influence of the reformation has not only been felt by the clergy, and the inferior members of the Roman Catholic church; but it has extended to the see of Rome, and to the sovereign pontiffs themselves, whose character, at a later period, has been very different from that of several of their predecessors. Many of them have been conspicuous for the virtues becoming their high station; and by their humanity, their love of literature, and their moderation, have made some atonement to mankind for the crimes of those who in former times occupied their places. Thus the reformation has eminently contributed to increase purity of manners, to diffuse science, and to inspire humanity. With the progress of the reformation we may also connect a variety of other important benefits, both to individuals and to society; and as they pertain to the investigation of truth and the improvement of science, to the promotion of liberty both civil and religious, to the diffusion of knowledge and virtue, and to the advancement of the best interests of mankind. But the details of the advantages resulting from the reformation to nations and private persons, to religion in general, and genuine Christianity in particular, would far exceed the limits to which we are confined.

See, on the subject of this article, Robertson's Hist. of Charles V., vol. ii. p. 113, &c. vol. iii. p. 44, &c. Moths's Eccl. Hist. Eng. ed. 1820. vol. iii. Burnett's Hist. of the Reformation, 2nd ed. For a comprehensive, and, upon the whole, a just sketch of the predistinguous causes, and beneficial consequences of the reformation, we refer the reader to a work which obtained the prize propounded by the National Institute of France, 15th of Germinal, in the year X. viz. "What has been the influence of the reformation by Luther on the political situation of the different states of Europe, and on the progress of knowledge?" The work is entitled "An Essay on the Spirit and Influence of the Reformation by Luther," by C. Villiers. We have two English translations, one by B. Lambert, and the other by James Mill, 8vo. 1825.

REFORMATION, Right of, see Reformation, the right which the princes of Germany claim to reform the church in their respective territories; as being invested with the spiritual as well as the temporal power.

The jus reformationis is annexed to the sovereignty; by this they have the power of conscience, the disposition of ecclesiastical revenues, &c. as they enjoyed the same at the treaty of Münster in 1648.

REFRACTION. Refractio, in Mechanica, the deviation of a moving body from its direct course, by reason of the different density of the medium it moves in; or a fixation and change of determination, occasioned by a body's falling obliquely out of one medium into another of a different density.

Thus a ball A (Plate XXXIX. Mechanica, fig. 14.) moving in the air in the line A B, and falling obliquely on the surface of the water C D, does not proceed straight to E, but deviates, or is reflected, to F. Again, if the ball moving in water in the line A B, should fall obliquely on a surface of air C D, it will not proceed straight to E, nor yet direct to F, but to G. Now the deviation in each case is called the refraction; and the two cases are distinguished by means of the perpendicular M; that E G being called refraction under the perpendicular, or to the axis of refraction; and the other E F, refraction from the perpendicular, or from the axis of refraction.

These refractions are supposed to arise hence, that the ball arriving at B, in the first case finds more resistance or opposition on the one side O, i.e. from the side of the water, that it did from the side P, or that of the air; and in the latter more resistance from the side P, which is now the side of the water, than the side O, which is that of the air.

The great law of refraction, then, which holds in all bodies, and all mediums, is that a body, falling obliquely out of a medium which resists it more, is refracted towards the perpendicular; and in passing out of a medium which opposes it less from another which opposes it more, it is refracted from the perpendicular.

Hence the rays of light falling out of air into water are refracted towards the perpendicular; whereas a ball thrown into the water is reflected from it; because water, which resists the motion of light less than air, resists that of the ball more; or, to speak more justly, because water, by its greater attraction, accelerates the motion of the rays of light more than air does; for that is the true cause of refraction, at least in light, shall be shewn under Refraction of Light.

To have a body refracted, it is necessary that it should fall obliquely on the second medium. In perpendicular incidence there is no refraction.
REFRACTION.

Vossius indeed, and Snellius, imagined they had observed a perpendicular ray of light undergo a refraction; a perpendicular object appearing in the water nearer than in reality it was; but this was to attribute that to a refraction of the perpendicular rays, which was owing to the divergence of the oblique rays after refraction, from a nearer point.

Yet there is a manifest refraction even of perpendicular rays found in glass CRYSTAL, which fee.

Rohault adds, that an oblique incident light be necessary in all other mediums we know of, yet the oblique must not exceed a certain degree; if it do, the body will not penetrate the medium, but will be reflected instead of being refracted.

Such cannon-balls, in sea-engagements, falling very obliquely on the surface of the water, are observed to mount aloft again, and frequently to sweep the men off from the opposite decks; and the like happens to the little stones with which children make their ducks and drakes.

The ancients confounded refraction with reflection, and it was for Isaac Newton who first taught us the just difference between them. He shows likewise, that there is a good deal of analogy between them, and particularly in the case of light.

The laws of refraction of the rays of light in mediums differently terminated, i.e. whose surfaces are plain, concave, convex, &c. make the subject of dioptics; which fee.

By refraction it is, that convex glaases, or lense, collect the rays, magnify objects, burn, &c. and hence the foundation of microscopes, telescopes, &c.

By refraction it is, that all remote objects are seen out of their real places; particularly, that the heavenly bodies are apparently higher than they are in reality, &c.

The refraction of the air has many times fo uncertain an influence on the places of celestial objects, very remote from the zenith, that wherever refraction is concerned, the conclusions deduced from observations that are much affected by it, will always remain doubtful, and too precarious in many cases to be relied upon. See Dr. Bradley, in Phil. Trans. N° 485.

See Atmopherical Refraction.

REFRACTION. In Optics, is an intersection or deviation of the rays from their rectilinear course upon falling obliquely out of one medium into another, of a different density.

The term refraction is derived from the distoction which it occasions in the appearance of an object viewed in part only by refracted light; thus, an ear, partially immersed in water, appears to be bent, on account of the refraction of the light, by which its lower part is seen, in its passage out of the water into the air.

Although no sensible light can penetrate more than 700 feet deep into the sea, and a length of seven feet of water has been found to intercept one-half of the light which enters it; yet in transparent substances (no medium being, strictly speaking, absolutely transparent) the greater part of the light penetrates to all distances with little interruption, and all rays, of the same kind, thus transmitted by the same surface, form with the perpendicular an angle of refraction, which is ultimately in a certain constant proportion to the angle of incidence; that is, for instance, one-half, three-fourths, or two-thirds, according to the nature of the surface. Thus, if the refractive properties of the substance were such, that an incident ray, making an angle of one degree with the perpendicular, would be so refracted as to make an angle of only half a degree with the same line, another ray, incident at an angle of two degrees, would be refracted, without sensible error, into an angle of one degree. But when the angles are larger, they vary from this ratio, their lines only preferring the proportion with accuracy; for example, if the angle of incidence at the supposed surface were increased to 90°, the angle of refraction would be 35° only, instead of 45°.

It does not appear that, before Descartes, any person attempted to explain the physical caufe of the refraction, and also the reflection of light, which he undertook to do by the resolution of forces, on the principles of mechanics; in conformitie of which was he obliged to suppose that light palls with more ease through a denser medium than a rare one; thus the ray A B (Plate XVIII. Optics, fig. 10.) falling obliquely upon a denser medium at B, is supposed to be acted on by two forces, one of them compelling it in the direction A C, and the other in A D, which alone can be affected by the change of medium; and since, after the ray has entered the denser medium, it approaches the perpendicular B H, it is plain that this force must have received an increase, whilst the other continued the same; for if B E be taken equal to B D, or C A, the consequence of the angle B H being less than A B C will be, that B H must be longer than B C or A D.

The first person who questioned the truth of this explanation of the cause of refraction was M. Fermat, who asserted, contrary to Descartes, that light suffers greater resistance in water than in air, and greater in gasses than in water; and he maintained that the resistance of different mediums, with respect to light, is in proportion to their denities. M. Leibnitz adopted the same general idea; and they reasoned upon the subject in the following manner. Nature, they say, accomplishes her ends by the shortest methods; light, therefore, ought to pass from one point to another, either by the shortest road, or that in which the least time is required. But it is plain that the line in which light palls, when it falls obliquely upon a denser medium, is not the most direct or the shortest; so that it must be that in which the least time is spent. And, whereas it is demonstrable, that light falling obliquely upon a denser medium (in order to take up the least time possible, in palling from a point in one medium to a point in the other) must be refracted in such a manner, that the lines of the angles of incidence and refraction must be to one another, as the different facilities with which light is transmitted in those mediums; it follows that, since light approaches the perpendicular when it palls obliquely from air into water (so that the line of the angle of refraction is less than that of the angle of incidence), the facility with which water suffers light to pass through it is less than that of the air; so that the light meets with greater resistance in water than in air. This method of arguing from final causes could not satisfy philosophers. Dr. Smith observes that it agrees only to the case of refraction at a plain surface; and that the hypothesis is altogether arbitrary. If he had endeavoured to accommodate his principle to concave and convex surfaces, as he had once proposed, he would soon have perceived its insufficiency. The easiest way for a ray to pass from a given point in any refracting medium into a vacuum, is in a perpendicular to the refracting surface, this being the shortest way, through any difficulty or resistance whatever; but this being reduced to nothing at the refracting surface, it may then take any other course in vacuo, without any farther difficulty; and, on the contrary, in returning back from the vacuum into the denser medium, it must take the shortest course through the same perpendicular as before. Thus, when the sun shines upon the atmosphere, all his rays should be refracted into lines tending to the centre of the earth, as being the shortest and easiest way through the atmosphere, and then we should see the sun exactly over our heads, in all places and at all times. Such is the strange confe-
consequence that follows from an hypothesis so arbitrary.

Descartes, in order to explain the law of refraction, supposed that every ray of light is composed of several smaller rays, which adhere to one another; and that they are refracted towards the perpendicular, in passing into a denser medium, because one part of the ray meets with more resistance than another part; so that the former traverses a smaller space than the latter; in consequence of which the ray muft necessarily bend a little towards the perpendicular. This hypothesis was adopted by the famous Dr. Barrow, who, as some say, was the author of it. On this hypothesis, it is plain that mediums of a greater refractive power must give greater refiilance to the passage of the rays of light than mediums of a less refractive power, which is contrary to fact.

The Bernouillis, both father and fon, have attempted to explain the caufe of refraction on mechanical principles; the former on the equilibrium of forces, and the latter on the same principles with the supposition of ethereal vortices; but neither of these hypotheses have gained much credit. M. Mairan supposes a fubtle fluid, filling the pores of all bodies, and extending, like an atmosphere, to a small distance beyond their surfaces; and then he supposes that the refraction of light is nothing more than a necessary and mechanical effect of the incidence of a small body in those circumstances. There is more, he says, of the refracting fluid in water than in air, in water than in glasses, and in general less in a denser medium than in one that is rarer. M. de Maupertuis supposes that the course which every ray takes, in passing from one medium into another, is that which requires the least quantity of action, which depends upon the velocity of the body, and the space it passes over; so that it is in proportion to the sum of the spaces, multiplied by the velocity with which bodies pass over them. From this principle he deduces the necessity of the angle of incidence being in a constant proportion to that of refraction: and also all the other laws relating to the propagation and refleétion of light.

Dr. Smith (in his Optics, Remarks, p. 70.) observes, that all other theories for explaining the refleétion and refractions of light, except Sir Isaac Newton's, suppose that it striking upon bodies, and is reftilled by them, which has never been proved by any deduction from experience. On the contrary, it appears by various considerations, and might be shown by Mr. Molyneux's and professor Bradley's observations on the parallax of the fixed stars, that their rays are not at all impeded by the rapid motion of the earth's atmosphere, nor by the object-glafls of the telescope through which they pass. And by Sir Isaac Newton's theory of refraction, which is grounded on experience only, it appears, that light is fo far from being reflected and retarded by refraction into any denser medium, that it is swifter there than in vacuo, in the ratio of the finite incidence in vacuo to the finite refraction into the denser medium. From some cases of the productions of colours, we are led to suppose, says Dr. Young (Left. Phil. vol. i. p. 460.) that the velocity of light must be smaller in a denser than in a rarer medium; and supposing this fact to be established, the existence of such an attractive force as Sir Isaac Newton supposed could no longer be allowed; nor, he says, could the fystem of the emanation of light, in opposition to that of the undulation of an ethereal medium, be maintained by any one. Priestley's Hilf. of Light, &c. p. 102, &c. p. 333, &c.

The refraction of light, Sir Isaac Newton shews, is not performed by the rays falling on the surface of bodies; but it is done without any contact, by the action of some power belonging to bodies, and extending to a certain distance without their surfaces; by which fame power, acting in other circumstances, they are also emitted and reflected.

Admitting that certain powers of attraction and repulsion belong to bodies, and extend to a certain distance beyond their surfaces, and supposing also that light confils of particles emitted from luminous bodies, Sir Isaac Newton demonstrates, in his "Principia," that the line of force of the angle of incidence must be always to the line of the angle of refraction in some certain ratio. For, as he proves geometrically, if two similar mediums are separated from each other by a space terminated on both sides by parallel planes, and a body, in its passage through that space, be attracted or impelled perpendicularly towards either of those mediums, and not agitated or hindered by any other force; and if the attraction be every where the same, at equal distances from either plane, taken towards the same hand of the plane, the line of incidence upon either plane will be to the line of emergence from the other plane in a given ratio.

In a corollary to this proposition he also shews, that if, instead of one parallel space, bodies be surrounded with several, or an infinite number of them, the attractive power of each of which differs from the next, increasing or decreasing, still, the ratio respecting any two contiguous ones being given, the ratio of the extremes will be given. He also demonstrates, that, if the caufe of refraction be the attraction of the refracting medium, the velocity of light before its incidence will be to its velocity afterwards, as the line of the angle of refraction to the line of the angle of incidence; so that light, in passing from a rarer medium into a denser, receives an increafe of velocity. The fame things being suppofed, he shews, that if the velocity before incidence be greater than afterwards, fo that the angle of emergence must alfo increafe, in confequence of the repulsive power prevailing over the attractive one, the body will at length be reflected; and that, in this case, the angle of refleétion must necessarily be equal to the angle of incidence.

That light does not confist of any mode of action upon a fluid medium, he concludes from having demonstrated that pressure cannot be propagated through a fluid in rectilinear directions, unless where the particles of the fluid lie in a right line, but must diverge into the unmovea spaces; and that every tremulous body, in an elastic medium, propagates the motion of the particles on every fide straight forwards. Admitting this, there is hardly any hypothesis that will agree with the phenomena of light, but that of particles emitted from the luminous body, affected by the attractions and repulsions of other bodies.

The fame arguments by which we have proved, that reflection (which lies) is performed without immediate contact, will go a great way towards demonstrating the fame of refraction: to which may be added the following ones.

1. Because, if when light falls out of glass into air with the utmost obliquity it will be transmitted at, it be then made to fall a little more obliquely, it becomes wholly reflected: for the power of the glafs, after it has refracted light emerging as obliquely as possible, supposing the rays to fall still more obliquely, will be too strong to let any of the rays pass; consequently, instead of being refracted, they will all be reflected.

2. Because in thin lamellae, or plates of glafs, light is reflected and transmitted several times alternately, as the thickenfs of the lamellae increases in arithmetical progression; for here it depends on the thickenes of the lamina which of the two the glafs shall do, whether reflect it, or let it be transmitted.

3. Because, whereas the power of other bodies both to reflect and refract light are very nearly proportional to their densities;
REFRACTION.

densities; yet unctuous and fulphureous bodies are found to reflect more strongly than according to their mere densities: for as the rays act more strongly on those bodies to kindle them than on others, do so they again, by their mutual attraction, act more strongly on the rays to refract them.

Lastly: Because not only those rays transmitted through glafs are found to be refracted, but also those falling in the air, or in a vacuum near their extremities, or even near the extremities of many opaque bodies, e. g. the edge of a knife, undergo a similar inclination, from the attraction of the body. See LAITY, and also INJECTION.

Thus, the manner in which refraction is performed by mere attraction, without contact, may be thus accounted for: Suppose $HI$ (Plate XVIII. Optics, fig. 17.) the boundary of two medium, $N$ and $O$; the first the rarer, e. g. $O$, the second the denfer, e. g. glafs; the attractions of the mediums here will be as their densities. Suppose $PS$ to be the distance to which the attracting force of the denser mediums exerts itself within the rarer. Let now a ray of light $AA$ fall obliquely on the surface which separates the mediums, or rather on the surface $PS$, where the action of the second and more refleting medium commences. All attraction being performed in lines perpendicular to the attractive body, as the ray arrives at $a$, it will begin to be turned out of its rectilinear course by a superior force, with which it is attracted by the medium $O$, more than by the medium $N$, i. e. by a force with which it is driven towards it in a direction perpendicular to its surface: hence the ray is bent out of its right line in every point of its passage between $PS$ and $RT$, within which distance the attraction acts. Between those lines, therefore, it describes a curve $AB$: but beyond $RT$, being out of the sphere of attraction of the medium $N$, it will proceed uniformly in a right line, according to the direction of the curve in the point $b$.

Again, suppose $H$ the denfer and more refleting medium, $O$ the rarer, and $HI$ the boundary, as before; and let $RT$ be the distance to which the denser medium exerts its attractive force within the rarer: even when the ray has passed the point $B$, it will be within the sphere of superior attraction of the denser medium; but that attraction acting in lines perpendicular to its surface, the ray will be continually drawn from its straight course $BM$ perpendicularly towards $HI$; thus, having two forces or directions, it will have a compound motion, by which, instead of $BM$, it will describe $BM$, which $BM$ will in strictness be a curve.

Lastly, after it has arrived in $m$, being out of the influence of the medium $N$, it will perpil uniformly in a right line, in the direction in which the extreme of the curve leaves it.

Thus we see how refraction is performed, both towards the perpendicular, and from it.

But note, the attraction of the denser medium, e. g. $N$, is continually diminishing, as the ray proceeds from $B$ towards the limit of attraction $RT$; because fewer and fewer parts still come to act; at $HI$, e. g. all the parts between that and $PS$ attract; but at $RT$, none but those in the line $HI$. Note, also, that the distance between $PS$ and $RT$ being small, when we consider refractions, no notice is taken of the curve part of the ray, but we consider it as consisting of two straight lines, $CB$, $AB$, or $m$, $AB$.

Sir IFAC Newton, not content with ascribing the reflecing, refraction, and inflection of light to powers of attraction and repulsion, extending beyond the surfaces of bodies, and producing effect in the manner above explained, propofes a conjecture concerning the physical cause of this attraction and repulsion: but his hypothesis is no less liable to difficulties and objections than the hypothesis of the mechanical production of the motion of light without attraction or repulsion. Does not the refraction of light, he fays, arise from the different density of an ethereal medium in different places, the light always receding from the denser parts of the medium? And is not the density of it greater in free and open spaces void of air, and other gross bodies, than within the pores of water, glafs, crystal, gems, and other compact bodies? For when light paffes through glafs or crystal, and falling very obliquely upon the further furface, is all refected, the total reflection ought to arise rather from the density and vigour of the medium without and beyond the glafs, than from the rarity and weaknesses of it. Does not the ethereal medium, in paffing out of water, glafs, crystal, and other compact and denfe bodies, into empty spaces, grow denfer and denfer by degrees, and by that means refraft the rays of light, not in a point, but by bending them gradually in curve lines? And does not the gradual condensation of this medium extend to some distance from the bodies, and thereby cause the inflections of the rays of light, which pafs by the edges of the denfe bodies, at some distance from the bodies?

Refraction, in Dioptrics, is the inflection or bending of the rays of light, in paffing the surfaces of glafs, lentes, and other transparent bodies of different densities.

Thus a ray, as $AB$ (Plate XVIII. Optics, fig. 11.) falling obliquely from the radiant $A$, upon a point $B$, in a diaphragmous surface, $HI$, rarer or denser than the medium along which it was propagated from the radiant; has its direction there altered by the action of the new medium; and instead of proceeding to $M$, it deviates, e. g. to $C$.

This deviation is called the refraction of the ray: $BC$ the refrafed ray, or line of refraction; and $B$ the point of refraction.

The line $AB$ is called the line of incidence, or ray of incidence; and, in respect of it, $B$ is also called the point of incidence.

The plane in which both the incident and refracted rays are found, is called the plane of refraction: a right line $BE$, drawn in the refracting medium perpendicular to the refraffing surface, in the point of refraction $B$, is called the axis of refraction: and a right line $DB$, drawn perpendicular to the refraffing surface, in the point of incidence $B$, along the medium through which the ray fell, is called the axis of incidence.

The angle $AB$, included between the incident ray and the refraffing surface, is called the angle of incidence; and the angle $AB$, included between the incident ray and the axis of incidence, is called the angle of inclination. The angle $MBC$, which the refracted ray makes with the incident, is called the angle of refraction: and the angle $CBE$, which the refracted ray makes with the axis of refraction, is called the refracted angle.

Refraction, general laws of. 1. A ray of light in its passage out of a rarer into a denser medium, e. g. out of air into glafs, is refracted towards the perpendicular, i. e. towards the axis of incidence.

Hence, the refracted angle is less than the angle of inclination: and the angle of refraction less than that of incidence; as they would be equal were the ray to proceed straight from $A$ to $M$. Hence, also, a ray perpendicular to the refraffing surface, will pafs through without being refracted, as it cannot be refracted to the perpendicular.

The physical caufe of which is, that the attraction of the denser medium, which, in an incidence oblique to its surface acts perpendicularly to that surface, draws the ray out of its course: this attraction, we fay, in a perpendicular incidence, acts in the direction of the ray.

2. The ratio of the line of the angle of inclination, to the
Refraction.

Fine of the refracted angle, is fixed and constant; viz. if the
refraction be out of air into glass, it is found greater than
as 114 to 76, but less than 115 to 76; that is, nearly as
3 to 2.

This ratio, assigned by Huygens, agrees with another of
Sir Isaac Newton, who makes the fine of the angle of inclina-
tion to the fine of the refracted angle, as 31 to 20;
which is, likewise, nearly as 3 to 2. Indeed, there is some
difference in the quantity of refraction, in different kinds of
glasses; but in physical matters, precifeness is not necessary.
In rain-water, Descartes found the ratio of the fine of the
angle of inclination, to the fine of the refracted angle,
as 250 to 187, that is nearly as 4 to 3; which agrees with
Sir Isaac Newton's observation, which makes it as 529 to 396.
In spirit of wine, the fame author makes the ratio as
100 to 73; which is not far from the eightieth of this ratio.
In air, he makes it as 3201 to 3200; and as to air, he
hears, that a ray of light, in traversing quite through the
atmosphere, is refracted the same as it would be, were it to
pass with the same obliquity out of a vacuum into air of equal
density with that in the lowest part of the atmosphere.

See the following table, in which the proportion of the
crystal, which measure the refractions of several bodies; the
densities of the bodies, estimated by their specific gravity;
and their refractive power, in respect of their densities, are
set down in separate columns.

Newton's Optics, edit. 3. p. 247.

M. Euler the younger, purifying a scheme suggested by
his father for ascertaining the refractive powers of trans-
parent liquors, made use of two Menificus glases, which
he put together when they were plunged in the fluid, the
refractive power of which he wanted to determine: the
edges of these glases being ground flat, they immediately
cohered, so that none of the fluid could escape; and then
they might both together be wiped, and used as one object-
glase in a long tube, which he could lengthen or shorten at
pleasure; and applying an eye-glas to it, the whole ob-
ervation he had to make was to measure the exact length of
his tube, when he could see through it most distinctly a
turret, which was at a considerable distance from him.

Or, when the focal distance was less than a foot, he only
observed, at what distance from a wall the image of an op-
posite window was the most distinct. Ac. Berlin. 1762, p. 302.

The refractive power of the fluids which he examined in
this manner, he expressed in the following tables.
The refractive power of some other fluids found by the
second pair of Meniscules, 16th August, 1761; Reaumur's
thermometer being 31 degrees above the freezing point.

| Spirit of Saxon soap            | 1.4088          |

That the refractive power of these fluids, thus determined
by M. Euler, may be more easily compared with Mr.
Haukkee's and Sir Isaac Newton's experiments, he reduced
the refraction of their observations into the following table,
exactly similar to his own.
The refractive power of certain fluids found by Mr.
Haukkee; see his Experiments, p. 292.

See Priestley's Hist. of Light, &c. p. 479, &c.
Whence the different refractive power in different fluids
arises, is not determined. Sir Isaac Newton shews, that in
many bodies, *e. g.* glas crystal, a felinite, pseudo-topaz,
&e. the refractive power is proportional to their densities;
only in sulphureous bodies, as camphor, linseed oil, olive,
amber, spirit of turpentine &c. the power is two or three
times greater than in other bodies of equal density; yet
even these have the refractive power with respect to each
other nearly as their densities.

Water has a refractive power in a middle degree be-
tween those two kinds of substances, and is, probably, of
a middle nature. Salts and vitriols have refractive powers
in a middle degree between those of earthy substances and
water, and accordingly are composed of those two kinds of
substances. Spirit of wine has a refractive power in a
middle degree between those of water and oily substances;
and accordingly seems to be composed of both, united by
fermentation. It appears, therefore, that all bodies seem
have their refractive powers proportional to their den-
sities, or very nearly, escaping so far as they partake of
more or less sulphureous oily particles, and thereby have
their refractive powers made greater or less. Whence it
seems reasonable to attribute the refractive power of all
bodies
REFRACTION.

Bodies chiefly, if not wholly, to the sulphureous parts with which they abound.

From the observations of M. Euler it appears, that there is no fluid, and probably no transparent substance of any kind, the refractive power of which is less than that of rain-water, or distilled water; and between air and rain-water there is no substance that has an intermediate refractive power.

After rain-water immediately follows well-water; but there are probably as many varieties in its refractive power as there are different wells. We may, however, conclude, that the ratio of refraction from air into well-water is contained between the limits of 1.336 to 1, and 1.337 to 1.

Spirituous liquors have a greater refractive power in proportion to their strength: but the ratio of refraction from air into any spirituous liquor is never less than 1.34, nor greater than 1.37.

There is, probably, no kind of salt, but what, being dissolved in water, increases its refractive power.

The solutions of salt of urine and of vitriol have the least refractive powers, and those of rock-salt and fulminate of silver the greatest; but the ratio of refraction from air into any saline solution, preserving the proportion of one ounce of salt to twelve of water, will be contained between the limits of 1.34 to 1, and 1.35 to 1.

Diluted vinegar, and the solution of gum arabic, have nearly the same refractive power with common French wine; and the refractive power of white of egg is the same as that of rectified spirit of wine.

Mineral alkali saturated, seems to have the same refractive power with very strong brandy.

Spirit of nitre and oil of tartar per deliquium have a medium refractive power between spirituous liquors and oils.

The refractive powers of oils approach the nearest to that of glafs, especially oil of turpentine, which had the greatest refractive power of all the fluids on which he had made experiments.

Sir Isaac Newton suspected that different degrees of heat might have some effect on the refractive power of bodies, but his method of determining the general refraction was not sufficiently accurate to ascertain this circumstance; but happily this method of M. Euler's proved to be well adapted to this purpose.

From his experiments made for this purpose, he infers, that the focal distance of a single lens of glafs diminishes with the heat communicated to it; and this diminution of the focal distance is not owing to the increase of bulk in the glafs by heat; for the effect of this change is both incon siderable, and of a contrary nature. There can be no doubt, therefore, but that this alteration in the focal distance is owing to a change in the refractive power of the glafs itself, which, as well as, probably, that of all other transparent substances, is increased by heat, and diminished by cold.

It may seem surprising that the focal distance of a single lens should decrease with heat, and yet that of the meniscuses filled with any fluid, should increase with heat; but M. Euler observes, that it by no means follows from hence, that these fluids are affected by heat in a manner different from glafs; and, after computing the effect of every circumstance of this complex experiment, of the two glasses, and the fluid combined, he concludes, that heat increases the refractive power of water, and of other fluids, as well as that of glafs.

He further observes, that as 66 degrees of heat diminished the focal distance 1/4 th part; whereas the diminution in this case was 1/8 th. From hence, says he, one may perhaps conclude, that when it is very cold, the change in the thermometer has a greater effect on the refractive power of the glafs than when it is very hot. But he acknowledges that experiments of this kind are not capable of so much precision as one could wish, and that, perhaps in reality, the 66 degrees made a change of 1/8 th, and the 33 degrees of 1/16 th; but he imagined that a great number of experiments, made in different temperatures of the air, might decide this question, especially if object-glasses of a very great focal distance were made use of.

The duke de Chaulnes, not satisfied with the methods used by Newton and others for determining the refractive power of glafs, propofed another mode of doing it, which is very ingenious, and, when well conducted, promising fac cels. He formed the glafs into plates, the surfaces of which were truly plane and parallel, and having placed small objects on each of them, he found, by means of a compound microscope, to which he applied the most ex quisite micrometer, the different distances at which they were distinctly visible, and compared them with the thicknesses of the glafs. This, he says, gives the proportion of the refraction of the angles of incidence and refraction in that kind of glafs directly. In this method he ascertained the mean refractive power of 15 kinds of glafs.

Dr. W. H. Wollaston has proposed a new method of examining refractive as well as dispersive powers, by prismatic refraction. This method was suggested by a consideration of Sir Isaac Newton's prismatic eye-glasses, the principle of which depends on the refraction of light at the inner surface of a dense refracting medium.

Since the range of inclination, within which total reflection takes place, depends not only on the density of the reflecting prism, but also on the rarity of the medium adjacent to it, the extent of that range varies with the difference of the densities of the two media. When, therefore, the refractive power of one medium is known, that of any rarer medium may be learned, by examining at what angle a ray of light will be reflected from it.

For instance, when any object is laid under a prism of flint-glasses, with air alone interposed, the internal angle of incidence at which the visual ray begins to be totally reflected, and at which the object ceases to be seen by refraction, is about 39° 10'; but when the object has been dipped in water, and brought into contact with the glasses, it continues visible, by means of the higher refractive power of the water, as far as 57° 30' of incidence. When any kind of oil, or any refrinous cement, is interposed, this angle is still greater, according to the refractive power of the medium employed; and, by cementation that refracts more strongly than the glafs, the object may be seen through the prism, at whatever angle of incidence it is viewed.

In examining the refractive powers of fluids, or of fusable substances, the requisite contact is easily obtained; but, with solids, which can in few instances be made to touch to any great extent, this cannot be effected without the interposition of some fluid, or cement, of higher refractive power than the medium under examination. Since the surfaces of a frustum of a pyramid are parallel, it will not effect the total deviation of a ray passing through it, and may therefore be employed without ciks of any error in consequence.

Thus, resin, or oil of lassafas, interposed between plate-glasses and any other prism, will not alter the refhin.

If, on the same prism, a piece of felinite and another of plate-glasses be cemented near each other, their powers may
be compared with the same accuracy as if they were both in absolute contact with it.

For such a mere comparison of any two bodies, a common triangular prism is best adapted; but, for the purpose of actual measurement of refractive powers, Dr. Wollaston has preferred the use of a square prism, because, with a very simple apparatus, it shews the fine of refractive power sought, without the need of any calculation.

Let A (Plate XVIII. Optics, fig. 12.) be a square or rectangular prism, to which any substance is applied at b, and let any ray of light parallel to cb be refracted through the prism, in the direction b'dc.

Then, if ef and ed be taken proportional to the fines that represent the refractive powers of the prism and of air, e'g', which is intercepted between f and the perpendicular e'g', will be the corresponding line to represent the refractive power of the medium b. For since e'd' (opposite to ef) is the angle of refraction, e'g' (opposite to ed) must be equal to the angle of incidence b'd'h; and ef : f'g' :: bd : dh :: fine of ebi : fine of bbd.

All, therefore, that is requisite for determining the refractive power of b, is to find the means of measuring the line e'g'. On this principle, the instrument in fig. 13 is constructed. On a board, ab, is fixed a piece of flat deal ed, to which, by a hinge at d, is jointed a second piece de, 10 inches long, carrying two plane fights at its extremities. At e is a second hinge, connecting ef, 15.83 inches long; and at the third at the other extremity of ef, by which g' is connected with it. At i also is a hinge, uniting the radius ig to the middle of ef; and then, since g moves in a circumference e'g'f, a line joining e and g would be perpendicular to e'g'.

The piece ed has a cavity in the middle of it, fo that, when any substance is applied to the middle of the prism P, it may continue to reflect horizontally on its extremities. When ed has been fo elevated, that the yellow rays in the fringe of colours (observable where perfect reflection terminates) are seen through the fights, the point g', by means of a vernier which it carries, shews by inspection the length of the sign of refraction sought.

The advantages which this method poffefles above the usual mode of examining refractive powers, are greater than they may at first sight appear. The usual practice has been, to form two surfaces of the substance under examination, so inclined to each other that the deviation occasioned by them might be measured. The inclination of these surfaces to each other must also be known; and hence the refractive power might be computed. But, in the method here proposed, it is sufficient to have only one surface, and the result is obtained at once, without computation.

The facility of determining refractive powers is consequently such as to render this property of bodies a very convenient test in many philosophical inquiries.

The following table exhibits a series of substances, arranged according to their refractive powers.

From the law laid down in the beginning of this article, it follows, that one angle of inclination, and its corresponding refracted angle, being found by observation, the refracted angles, corresponding to the several other angles of inclination, are easily computed. Now, Zahnius and Kircher have found, that if the angle of inclination be 70°, the refracted angle will be 38° 50' ; on which principle Zahnius has constructed a table of refractions out of air into glafs, for the several degrees of the angle of inclination; a specimen of which follows:

Hence it appears, that if the angle of inclination be les than 20°, the angle of refraction out of air into glafs is almoft one-third of the angle of inclination; and, therefore, a ray is refracted to the axis of refraction, by almoft a third part of the quantity of its angle of inclination. And on this principle it is that Kepler, and moft other dioptrical writers, demonstrate the refractions in glafs; though in estimating the law of these refractions, he followed the example of Alhazen and Vitellio, and sought to discover it in the proportion of the angles, and not in that of the lines.

The true law of refraction was first discovered by Willebrord Snellius, professor of mathematics at Leyden; who found by experiment that the refractions of the complements, or co-rectants, of the angles of incidence and refraction, are always in the fame ratio. It is vulgarly attributed, however, to Descartes; who having feen it in Snellius's MS., first published it in his Dioptrics, without naming Snellius; as we are informed by Huygens. The form in which Descartes gives this law is different from that of Snellius, and in general more commodious; but it might have been easily deduced from it. According to him, the line of the angle of refraction always bears the fame proportion to the line of the angle of incidence. Indeed, as the rays of light are not all of the fame degree of refrangibility, this contant ratio must be different in different kinds. The ratio, therefore, obferred by authors, is to be understood of rays of the mean refrangibility, i.e. of green rays. The difference of refraction between the lead and moft refrangible rays, that is, between violet and red rays, for Isaac Newton fhews is about the 27/t part of the whole refraction of the mean refrangible; which difference he owns is fo small, that there seldom needs to be any regard paid to it.

3. When a ray paffes out of a denser into a rarer medium, e. g. out of glafs into air, it is refracted from the perpendicular, or from the axis of refraction. And hence the angle of refraction is greater than the angle of inclination.

Hence, also, if the angle of inclination be less than 30°, MBC (Plate XVIII. Optics, fig. 11.) is nearly equal to one-third of MBE; therefore MBC is one-half of CBE; consequently, if the refraction be out of glafs into air, and the angle of inclination les than 30°, the ray is refracted from the axis of refraction by almost one-half part of the angle of inclination. And this is the other dioptrical principle used by moft authors after Kepler, to demonstrate the refraction of glafs.

If the refraction be out of air into glafs, the ratio of the line of inclination to the line of the refracted angle is as 3 to 2, or, more accurately, as 17 to 11; if out of air into water, as 4 to 3; therefore, if the refraction be the contrary way, viz. out of glafs or water into air, the ratio of the lines, in the former cafe, will be as 2 to 3, or 11 to 17, and in the latter as 3 to 4.

Hence, if the refraction be from water or glafs into air, and the angle of incidence or inclination be greater than about 48° 5 in water, or greater than about 40° in glafs, the ray will not be refracted into air, but will be reflected into a line, which makes the angle of refLECTION equal to the angle of incidence; because the lines of 48° 3 and 40° are to the radius as 3 to 4, and as 11 to 17 nearly, and therefore when the line has a greater proportion to the radius than as above, the ray will not be refracted.

4. A ray falling on a curve surface, whether convex or concave, is refracted after the fame manner as if it fell on a plane which is a tangent to the curve in the point of incidence.

For the curve and plane surface touching it, have an infinitely small part common to them both (each being originally generated by the flux of a point). But a ray is refracted in such a little part; therefore it is the fame as if it were refracted in such a plane.

5. If a right line E F (Plate XVIII. Optics, fig. 14.) cut a refracting surface, GH, at right angles; and if, from any point in the denser medium, as D, be drawn DC parallel to the incident ray AB; this will meet the refracted ray in C; and will be to it as the finite of the refracted angle to the fine of the angle of inclination.

For o = x; but if BC pafs out of a denser medium into a rarer, y > x; and out of a rarer into a denser, y < x; therefore, in the former cafe, y > o, in the latter y > o; consequently, in the former, o + u > y + u; in the latter y + u < o + u. But in the one case o + u, and in the other y + u, are equal to two right angles; therefore, o + u in this, and y + u in the other, are les than two right angles, and consequently DC will meet BC. But since o = u, or the angle of inclination, and y is the refracted angle, it is evident that C B is to C D as the line of the angle o to the line of the angle y, or in the ratio of the line of the angle of inclination to the line of the refracted angle.

Hence, if BC pafs out of glafs into air, it is in a subfequalterate ratio to C D; if, on the other hand, it pafs out of air into glafs, it is in a subequalterate ratio to C D.

Hence, also, if light pafs out of water into air, C B is in a subsequalterate ratio to C D; if out of air into water, in a sequalterate. See figs. 14 and 15.

REFRACTION in plane surfaces, locus of. 1. If parallel rays be refracted out of one transparent medium into another of a dif-
REFRACTION.

a different density, they will continue parallel after refraction. The physical reason is, that, being parallel, their obliquity, or angle of incidence, is the same; but, at equal obliquities, we have shewn the refraction is equal; consequently the parallelism, which they had before the refraction, will be retained after it.

But this may be also demonstrated geometrically; thus, if the rays be perpendicular to the refracting surface, they will pass without any refraction; consequently being parallel before their passage, they will be so after it. If they fall obliquely, as A B and C D (fig. 16.), the angles of incidence r and y, and, consequently, also the angles of inclination x and y, will be equal. But the ratio of the angles of refraction m and n; therefore the angles of incidence x and y have the same ratio to the angles of refraction m and n, and also the angles x and y, are equal; consequently the refracted rays are parallel.

Hence a glafs, plane on both side, being turned directly to the sun, the light passing through it will be propagated after the same manner as if the glafs were away; for the rays being perpendicular, will pass without refraction. If the glafs be turned obliquely to the light, the light, after refraction, will be of the same intensity as before, the intensity depending upon the sparsity or closeness of the rays, and on the angle with which they strike the object, or the eye; both which are here unvaried.

2. If two rays D C and C P. (fig. 17.) proceeding from the same radiant C, and falling on a plane surface of a different density, so that the points of refraction D and P are equally distant from the catenatus of incidence G K, the refracted rays D F and P Q have the same virtual focus, or the same point of refraction G.

Hence, 1. Since, in rays very near each other, the distance from the catenatus is the same as to a center, very near rays will diverge from the same point G, i.e. they will have the same virtual focus G.

And hence, 2. When refracted rays, falling on the eye placed out of the catenatus of incidence, are either equally distant from the catenatus, or very near each other, they will fall upon the eye, as if they came to it from the point G; consequently the point C will be seen by the refracted rays as in G.

3. If a ray C D fall obliquely out of a thinner into a denser medium, having a plane surface, the distance of the refracting point C K will have a less ratio to the distance of the point of refraction, or virtual focus, K G, than the sine of the refracted angle to the sine of the angle of incidence. But if the distance of the point of refraction, from the catenatus of incidence K D, be less than the tenth or one-hundredth part of the distance of the refracting point C K, and if in the former case the tenth, and in the latter the hundredth, part of it be so small, that it cannot be ascertained, or need not be observed, then will C K be to K G, as to fenfe, in the ratio of the sine of the refracted angle, to the sine of the angle of incidence.

Hence, 1. If the refraction be out of air into glafs, the distance of the point of refraction of rays near the catenatus is equiform to the distance of the point of refraction, or point of remote rays greater than equiform. But if the refraction be out of air into water, the distance of the same point will be equiform, when the rays are near the catenatus; and when more remote, greater than equiform.

Hence, 2. If the eye be placed in a denser medium, objects in a rarer will appear more remote than they are; and the place of the image, in any given case, may be determined from the ratio of the refraction. Thus, to fishes swimming under water, objects out of the water must appear farther distant than in reality they are.

4. If a ray D G fall obliquely out of a denser into a rarer medium A B, the distance of the refracting point G K has a greater ratio to the distance of the point of refraction K C, than the sine of the refracted angle has to the sine of the angle of inclination. In the other case of the preceding theorem, K G will be to K C, as to sinus, in the ratio of the sine of the angle of refraction, to the sine of the angle of inclination.

Hence, 1. If the refraction be out of glafs into air, the distance of the point of refraction of the rays near the catenatus of incidence is subequiform to the distance of the refracting point; that of the more remote rays is less than subequiform.

But, 2. If the refraction be out of water into air, the distance of the point of refraction of rays near the catenatus is subequiform; of those more remote, less than subequiform.

And, 3. The eye, therefore, being placed in a rarer medium, objects placed in a denser, appear nearer than they are; and the place of the image may be determined in any given case by the ratio of refraction. Hence, the bottom of a vessel full of water is raised by refraction to a third part of its height, with respect to an eye perpendicular to the refracting surface; and hence fishes, and other bodies under water, appear nearer than they really are.

5. If the eye be placed in a rarer medium, an object seen in a denser medium, by a ray refracted in a plane surface, will appear larger than it really is. If the object be in a rarer, and the eye in a denser medium, the object will appear less than it is. And, in each case, the apparent magnitude is to the real one in a ratio compounded of the distance of the point to which the rays tend before refraction, from the refracting surface D E (fig. 18.) to the distance of the eye G L from the same, and of the distance G M of the object A B from the eye, to its distance F M from a point F, to which the rays tend before refraction.

Hence, 1. If the object A B be very remote, F M will be physically equal to G M; and, therefore, the real magnitude M B is to its apparent one M H, as G L to F L, or the distance of the eye G from the refracting plane to the distance of the point of convergence F from the same plane.

Hence, 2. Objects under water, to an eye in the air, appear larger than they are; and to fishes under water, objects in the air appear less than they are.

REFRACTION. Latus of, in spherical surfaces, both concave and convex. 1. A ray of light D E (fig. 19.) parallel to the axis of a denser sphere, after a single refraction in E, falls in with the axis of the point F, beyond the centre C.

For the femidiameter C E, drawn to the point of refraction E, is perpendicular to the surface K L, and is therefore the axis of refraction; but a ray out of a rarer into a denser medium, we have shown, is refracted towards the perpendicular, or the axis of refraction; therefore the ray D E will converge to the axis of the sphere A F; and will, therefore, at length concur with it, and that beyond the centre C, in F; because the angle of refraction F E H is less than the angle of inclination C E H.

2. If a ray D E fall on a spherically convex surface of a denser medium, parallel to its axis A F; the femidiameter C E will be to the refracted ray E F in the ratio of the sine of the angle of refraction, to the sine of the angle of inclination; but the distance of the focus, or point of concurrency from the centre C F, is to the refracted ray F E, in the ratio
ratio of the sine of the refracted angle, to the sine of the angle of inclination.

3. If a ray D E fall on a denser spherical convex surface K L, parallel to the axis A F, the distance of the focus from the refracting surface F B must be to its distance from the centre F C, in a ratio greater than that of the sine of the angle of inclination, to the sine of the refracted angle. But if the rays be very near the axis, and the angle B C E be very small, B F will be to C F very nearly in the ratio of the sine of the angle of inclination, to the sine of the refracted angle.

Hence, 1. If the refraction be out of air into glass; in the case of rays near the axis, F B : F C :: 3 : 2; in the case of rays more remote from the axis, F B : F C > 3 : 2; consequently, in the former, B C : F C :: 1 : 2. And hence, in the latter, B C : F C < 1 : 2.

Hence also, 2. If the refraction be out of air into water; in the case of rays near the axis, F B : F C :: 4 : 3; in the case of rays more remote from the axis, F B : F C > 4 : 3; consequently, in the first case, B C : F C :: 1 : 3. And hence, in the latter, B C : F C > 1 : 3.

And hence, 3. Since the point of dispersion F is farther from the centre C, if the refraction be in water than in air; rays will be less dispersed in the latter case than in the former.

4. If the ray H E (fig. 20.) fall parallel to the axis A F, from a denser upon the surface of a spherical convex medium the refracted ray will conform with the axis A F, in the point F; so that the distance of the point of contact from the centre C F, may be to the refracted ray F E, in the ratio of the sine of the refracted angle, to the sine of the angle of inclination.

5. If a ray E D fall parallel to the axis A F on the spherically convex surface K L of a rarer medium, out of a denser, the distance of the point of dispersion from the centre F C, is to its distance from the surface F B, in a ratio greater than that of the sine of the refracted angle to the sine of the angle of inclination. But if the rays D E be very near the axis A F, the ratio will be very nearly the same with that of the sine of the refracted angle to the sine of the angle of inclination.

Hence, 1. If the refraction be out of glases into air, in the case of rays near the axis, F C : F B :: 3 : 2; in the case of rays more remote from the axis, F C : F B > 3 : 2.

2. If the refraction be out of water into air; in the former case, F C : F B :: 1 : 2. Therefore, in the case of rays more remote from the axis, F C : F B > 3 : 2.

3. Since then the point of dispersion F is more remote from the refracting surface K L, if the rays proceed out of water, than if they pass out of glases into air; parallel rays are less dispersed in the former case than in the latter.

6. If a ray H E (fig. 19.) fall parallel to the axis A F, out of a rarer, on the surface of a spherically convex denser medium; the refracted ray E N will be driven from the point of the axis F; so that E F will be to F C in the ratio of the sine of the angle of inclination, to the sine of the refracted angle.

7. If a ray E H fall parallel to the axis F B on the concave surface K L of a spherically denser medium, from a rarer; the distance of the point of dispersion from the refracting surface F B, is to its distance from the centre F C, in a ratio greater than that of the sine of the angle of inclination, to the sine of the refracted angle. But if the rays be very near the axis, and the angle B C E be very small, B F will be to C F very nearly in the ratio of the sine of the angle of inclination, to the sine of the refracted angle.

Hence, 1. If the refraction be out of air into glass; in the case of rays near the axis, F B : F C :: 3 : 2; in the case of rays more remote from the axis, F B : F C > 3 : 2; consequently, in the former, B C : F C :: 1 : 2. And hence, in the latter, B C : F C < 1 : 2.

Hence also, 2. If the refraction be out of air into water; in the case of rays near the axis, F B : F C :: 4 : 3; in the case of rays more remote from the axis, F B : F C > 4 : 3; consequently, in the first case, B C : F C :: 1 : 3. And hence, in the latter, B C : F C > 1 : 3.

And hence, 3. Since the point of dispersion F is farther from the centre C, if the refraction be in water than in air; rays will be less dispersed in the latter case than in the former.

8. If the ray H E (fig. 20.) fall parallel to the axis A F, from a denser upon the surface of a spherical concave rarer medium the refracted ray will conform with the axis A F, in the point F; so that the distance of the point of contact from the centre C F, may be to the refracted ray F E, in the ratio of the sine of the refracted angle, to the sine of the angle of inclination.

9. If a ray H E fall parallel to the axis A F on the concave surface of a rarer medium out of a denser, the distance of the focus from the centre F C will be to its distance from the refracting surface F B in a greater proportion than the sine of the refracted angle, to the sine of the angle of inclination. But if the rays be very near the axis, F C will be to F B in the proportion of these lines.

Hence, 1. If the refraction be out of glases into air; in the case of rays near the axis, F C : F B :: 3 : 2; in the case of rays more remote from the axis, F C : F B > 3 : 2.

Whence, in the former case, B C : F C :: 1 : 2.

2. If the refraction be out of water into air; in the case of rays near the axis, F C : F B :: 4 : 3; in the case of rays more remote, F C : F B > 4 : 3.

Whence, in the former case, B C : F C :: 1 : 3.

For the demonstration of these several laws of refraction, we refer to Wollaston's Elem. Math. &c. tom. iii. p. 179, &c. See also LENS.

REFRACTION in a glass prism. If a ray of light D E (fig. 21.) fall obliquely out of air on a prism A B C; being refracted towards the perpendicular, instead of proceeding to F, it will decline to G, i.e. towards a line H I, drawn perpendicular to the surface A B in the point of refraction E. Again, since the ray E G, passing out of the glases into air, falls obliquely on C B, it will be refracted to M, so as to recede from the perpendicular N G O. And hence arise the various phenomena of the prism. See COLOUR and REFRACTORINESS.

REFRACTION in a convex lens. If parallel rays, A B C, D, and E F (fig. 22.) fall on the surface of a lens 2 B 3 K, the perpendicular ray A B will pass unrefracted to K, where emerging into air perpendicular, as before, it will proceed straight to G. But the rays C D and E F, falling obliquely out of air into glases, in D and F, will be refracted towards the axis of refraction (i.e. towards lines H I and L M, drawn perpendicular to the refracting surface in the points of refraction D and F) and decline to Q and P. Again, emerging obliquely out of the glases into the surface of the air, they will be refracted from the perpendicular, and, therefore, D Q will not proceed to X, but to G; and F P, not to V, but to G; thus, likewise, might all the other rays, falling on
the surface of the glass, be seen to be refracted so as to meet the wall about the point $G$. See Focus and Lens.

Hence the great property of convex glasses; viz., that they collect parallel rays, or make them converge into a point.

REFRACTION in a concave lens. Parallel rays $A B C D$, and $E F$ (fig. 22), falling on a concave lens $G B H I M K$, the ray $A B$, falling perpendicular on the glass at $B$, will pass unrefracted to $M$, where being still perpendicular, it will pass into the air without refraction, to $L$. But the ray $C D$, falling obliquely on the surface of the glass, will be refracted towards the perpendicular $N D O$, and proceed to $Q$; and the ray $D Q$, again falling obliquely out of the glass upon the surface of air, will be refracted from the perpendicular $R Q S$, and proceed to $V$. After the same manner the ray $E F$ be shown to be refracted to $Y$, and thence to $Z$.

Hence the great property of concave glasses; viz., that they diverge parallel rays, or make them diverge. See Lens and Mirror.

REFRACTION in a plane glass. If parallel rays $E F G H$, $I L$ (fig. 24) fall obliquely on a plane glass $A B C D$, the obliquity being the same in all, by reason of their parallelism, they will be all equally refracted towards the perpendicular; and according, being still parallel at $M, O, Q$, they will pass out into the air equally refracted again from the perpendicular, and parallel.

Thus will the rays $E F$, $G H$, and $I L$, at their entering the glass, be incident towards the right; and in their going out as much incident to the left; so that the first refraction is here undone by the second; though not so as that the object is seen in its true place. For the ray $B Q$, being produced back again, will not coincide with the ray $I, L$, but will fall to the right of it; and this the more as the glass is thicker; however, as to matter of colour, the second refraction does really undo the first. See Colour.

REFRACTION in Iceland or Island crystal. See Iceland Crystal. Dr. Young, who maintains that radiant light consists in undulations of the luminoferous ether, takes occasion to make some remarks on Sir Isaac Newton's theory of the peculiar refraction in Iceland crystal. Newton, he says, has advanced the singular refraction of the Iceland crystal, as an argument that the particles of light must be projected corpuscles; since he thinks it probable that the different sides of these particles are differently attracted by the crystal, and since Huygens has confessed his inability to account, in a satisfactory manner, for all the phenomena. But contrary to what might have been expected from Newton's usual accuracy and candour, he has laid down a new law for the refraction, without giving a reason for rejecting that of Huygens, which Mr. Hâly has found to be more accurate than Newton's; and, without attempting to deduce from his own system any explanation of the more universal and striking effects of doubling prisms, he has omitted to observe, that Huygens's most elegant and ingenious theory perfectly accords with these general effects, in all particular, and of course derives from them additional pretensions to truth; this he omits, in order to point out a difficulty for which only a verbal solution can be found in his own theory; and which will probably long remain unexplained by any other.

Dr. Wollaston, in his paper on the oblique refraction of Iceland crystal, confirms the experiments of Huygens on this substance, with additional evidence, deduced from the superiority of his mode of examining the powers of refraction. He observes that Dr. Young has already applied the Huygenian theory with considerable success to the explanation of several other optical phenomena, and that it appears to be strongly supported by much coincidence of the calculations deduced from it, with the results of these experiments, as could have scarcely happened to a false theory.

In ordinary cases, the incident undulations are of a spherical form; but in the Iceland crystal light appeared to Huygens to proceed as if the undulations were portions of an oblate spheroid, of which the axis is parallel to the short diagonal of an equilateral piece of the crystal, and its centre the point of incidence of its ray. From this spheroidal form of the undulations, he deduces the obliquity of refraction; and lays down a law observable in all refractions, at any surface of the sp啖r, whether natural or artificial, which bears the closest analogy to that which obtains, universally, at other refractory surfaces; for as, in other cases, the ratio is given between the sine of incidence and sine of refraction, (or ordinate of the spheroidal undulation propagated,) so in the Iceland crystal, the ratio between the sine of incidence and ordinate of refraction (in any one section of the spheroidal undulation in a given ratio, but different in different planes.

Dr. Wollaston observes, that though we do not fully understand the existence of a double refraction, and are utterly at a loss to account for the phenomena occurring upon a second refraction, by another piece of the sp啖r, yet that the oblique refraction, when considered alone, is nearly as well explained as any other optical phenomenon. Phil. Trans. 1801 and 1802.

REFRACTION, Particular laws of, in different kinds of lenses; see Lens.

REFRACTION. Atmospheric, is generally considered under two distinct heads; viz. astronomical refraction, which is that relating to the refraction of the moon, stars, and other celestial bodies; and terrestrial refraction, or that which takes place in terrestrial observations.

It appears, from the article Refraction, that a ray of light is refracted in passing obliquely out of one medium into another of different density; and as the atmosphere may be considered as composed of an infinitude of fila, whose density increase as they are farther from the earth, the luminous rays which pass through it are acted on as if they passed successively through media of increasing density, and are therefore refracted more and more towards the earth, as the density augments, that is, as they approach the eye of the observer. In consequence of this it is, that rays from objects, whether celestial or terrestrial, proceed in curves which are convex towards the earth; and since the mind always refers the place of objects to the direction in which the rays reach the eye, the observer is drawn towards the curve at that point, it follows, that the apparent or observed elevation of objects is always greater than the true one, at least with the exception of some few remarkable anomalies which sometimes, in terrestrial observations, produce a contrary effect, and of which we have stated a few particular instances under the article Mirage, and on which subject some other curious facts are recorded in a memoir of professor Viney's, in the Phil. Trans.; in Nicholson's Philosophical Journal, 167; and more particularly by M. Monge, in vol. i. of the "Decade Egyiptienne." Referring the reader therefore to these works, to which we ought also to add the memoir by M. Biou, in vol. xi. of the National Institute, for an account and explanation of these phenomena, we shall confine our present observations to those cases only, in which an uniform law is supposed to have place, and which, as we have seen, has a constant tendency to augment the observed altitude of both celestial and terrestrial objects.
REFRACTION.

objects. In order to submit the phenomena of refraction to strict mathematical investigation, it must be observed that, in consequence of the inconsiderable height of the atmosphere, and its spherical form, a luminous ray impinging upon it, even in the most unfavourable case, that is directly in the horizon, traverses only a small quantity of this medium; and in this case, if the atmosphere is calm, the density of the air at equal heights above the level of the sea is everywhere the same. Therefore, in supposing the earth spherical, a supposition which may be admitted, in the present case, without any sensible error, we may consider the atmosphere as composed of successive spherical concentric shells, or strata, of which the density diminishes from the surface of the earth upwards.

Let us conceive, now, a luminous ray, coming from a distance, to penetrate into one of the supposed spherical shells; then, if through the common centre of these shells, which is the same as the centre of the earth, we suppose a plane to pass in the direction of the luminous ray, the spherical beds of the atmosphere will be divided into two equal portions, which acting equally upon the ray, can produce no deviation of it from that plane; whence it follows, that the effect of refraction is entirely produced in a vertical direction, and in such a manner as to augment the apparent altitudes of the heavenly bodies, and consequently to diminish their zenith distances.

But the intensity of these effects will not be the same at all heights, for we know that in all cases the quantity of refraction depends upon the obliquity of incidence, and therefore the refraction in the zenith is equal to zero, and increases from that point to the horizon, where it is the greatest.

If, now, we knew the law by which the density of the air is diminished in ascending from the earth, that is, if we knew the difference in the density of any two consecutive strata, it would be comparatively a direct and easy problem to find the whole amount of refraction for any given angle of observation; but unfortunately the uniformity of decrease in the density of the atmosphere, which, according to theory, is in geometrical progression, is so much interrupted by the multitude of causes which may tend to produce this effect, that it is found that the quantity of refraction computed on this principle, will by no means agree with that deduced from actual observation. It has been, however, demonstrated, that the quantity of refraction, in all cases exceeding 10 or 12 degrees of elevation, is not sensibly affected by any irregularity in the law of density, in the strata of which we have supposed the atmosphere to be composed, but that it depends simply upon its pressure and temperature at the time and place of observation, which are indicated at the time by the barometer and thermometer. It was formerly thought, also, that refraction was influenced by the degree of humidity and dryness of the air; but from a great variety of interesting and accurate experiments, carried on by M. M. Biot and Arrago, it appears indisputably established, that no sensible effect is thence produced. See a memoir on this subject by the former author, in vol. x. of the National Institute.

But before we proceed farther on this interesting subject, it will be proper to give a sketch of the several improvements which the theory has experienced in the hands of different celebrated astronomers; in doing which we shall avail ourselves of a memoir, published by Dr. T. S. Evans in the Philosophical Magazine, which contains a minute and circumstantial detail of many important particulars connected with this subject. There appears to be but little doubt that the astronomic refraction was known to the ancients, since it is expressly mentioned by Ptolemy, although not made use of in his calculations. He says, near the end of the 8th book of the Almagest, that in the rising and setting of the heavenly bodies, there are changes which depend upon the atmosphere, and he mentions it more at length in a work on optics, which, unfortunately, has not been handed down to us. Allazen, an Arabian writer, who is generally supposed to have lived about the year 1100, and to have taken the greater part of his optics from the works of Ptolemy, speaks also decidedly of it, and shews the manner of convincing ourselves of it by experiment. "Take," says he, "an armillary, which turns round its poles, and measure the distance of a star from the pole of the world when it passes near the zenith of the meridian, and when it is rising or setting near the horizon, and you will find the distance from the pole less in the latter case." He then demonstrates that this must arise from refraction, but he does not state its quantity.

In the collection of observations made by Bernard Walter, and published by Willebrode Snell in 1618, it is stated, that the observations were so exact, that they pointed out to Walter the quantities by which the altitudes of the stars and planets were increased on account of the refraction.

Tycho Brahe, however, appears to be the first who asserted, with any degree of accuracy, that the refraction elevates the heavenly bodies rather than half a degree when on the horizon. (See Progymn. p. 15.) But either his instruments or his observations were not sufficiently correct to determine it with certainty for all degrees from the zenith to the horizon; and, accordingly, when these failed, the rei were supplied by conjecture. He believed that the sun's refraction was 34' in the horizon, and that it became insensible at 45° of altitude. For the stars, however, he assumed an entirely different quantity, viz. 30' in the horizon; but this, according to him, terminated at only 20° of altitude.

The following is the manner in which it is related (Encyc. Method.) that Tycho made this discovery. He had determined, with one or two instruments extremely well made, the latitude of the place by observations of Polaris above and below the pole. He determined it also by the sun's altitude in both solstices, and found it four minutes less in the latter. At first he doubted the goodness of his instruments, and therefore constructed, with the utmost care, as many as ten others, of different sizes and forms, but they all gave nearly the same results. He could, therefore, no longer attribute this difference in the two determinations of the latitude to any defect in the observations, but endeavoured, by an attentive consideration of the subject, to find out the cause of this singular phenomenon. At length he supposed it could only arise from the refraction which elevated the sun at the winter solstice, having then only 11° of elevation above the horizon. This result agreed very well with the principles of optics; but still Tycho Brahe could scarcely persuade himself that the refraction was sufficiently large to produce so great a difference. On this account, he made other instruments of ten feet diameter, whose axes corresponded exactly with the pole of the world, and with these he measured the declination of the stars out of the meridian. He then found, that even in summer the refraction, although insensible at the meridian altitude of the sun, was very considerable near the horizon, and amounted to half a degree in the horizon. See Progymn. p. 79—104. Street's Astr. Carol. p. 119.
REFRACTION.

In this state the refraction remained for many years. Even Riccioli, in 1665, supposed it nothing at about 26° of altitude; but he thought the moon had only 20° of horizontal refraction in summer, the sun 30°, and the stars 35° 37'. It was not till after the year 1672, that a tolerably near table of refraction made its appearance, when the elder Caffini took the subject into consideration. (Mem. de l'Acad. tom. v. p. 81.) What led to this was the voyage of Richer to Cayenne in that year, upon the utility of which some very excellent remarks were made by Caffini, shewing how far observations made in a situation so near the equator tended to confirm or disprove certain theories derived from observations made in Europe. Several very useful deductions were drawn from a comparison of those made both at Paris and Cayenne; among others, the refraction was settled upon more accurate elements than heretofore, and a new table computed, for the first time, of its quantity, for all degrees up to the zenith; an abridgment of which is given below:

</table>

From the relation of his grandson it appears, however, that Caffini had at one time computed three tables of refraction for all altitudes; one for winter, another for summer, and a third for spring and autumn; but several doubts having been suggested to him respecting this arrangement, although in appearance conformable to nature, and principally the observations of Richer at Cayenne, where the refraction was found little different from that at Paris, he changed his opinion; and judging, that since the great difference of heat of the torrid zone from that of the temperate zone, which we inhabit, does not cause sensible differences in the refraction; therefore the greatest heat or cold of our climate could not change it much; and he then fixed upon one table, which was that used by the astronomers of the Royal Observatory of Paris up to the year 1745.

It was always thought, before the time of Caffini, that the refraction did not extend its influence higher than 45° of altitude; and he is generally considered as the first who proved that it reached all the way to the zenith. He also supposed that near the equator the horizontal refraction was less than in our climate by about one-third; that this difference decreased as far up as 60°, after which it was the same nearly for both climates.

From this discovery it followed, as a natural consequence, that the refraction must be greater near the pole than at Paris; and this was shortly afterwards proved to the Academy by the publication of a work expressly on that subject. (Refractione solis incedentis. &c. Holmiae, 4to. 1605.) The king of Sweden, being, in 1694, at Tornoe, in West Bohemia, near the latitude of 65° 45', and observing that the fun did not set there in the summer solstice, sent the following year some mathematicians to make more certain and exact observations of this curious phenomenon. They were contained in this book, and Mefrs. Caffini and De la Hire concluded from them, that in the latitude of 65° 45', the horizontal refraction must be 58', or nearly double of that at Paris.

According to an observation made by some Dutchmen who passed the winter of 1596—7, in Nova Zembia, in latitude 76° north, the fun, which had entirely disappeared the 14th of November, began to rise again the 24th of January, viz., six days sooner than was expected, according to astronomical calculations. If so, when the fun has been two or three months under the horizon, as the Dutchmen observed in 1597, the cold becomes dreadful, and perhaps the refraction increaseth prodigiously. M. le Mommier affirms, that he was found by the observations printed in 1599, that on the 24th and 25th of January 1597, there were more than 48° degrees of refraction; that he could neither explain these observations, reject them as doubtful, nor suppose any error, as was done by most of the other astronomers, Kepler, Caffini, Scotto, and, lately, M. le Gentil, in his Voy. dans les Mers des Indes, tom. i. p. 395. tom. ii. p. 332, who maintained that there were errors in the observations, and accordingly read a memoir on the subject. If it were not so difficult a task to winter in these high latitudes, we might expect such observations as would remove all doubt on the subject; and, perhaps, bring others to light of such great or greater importance.

The refraction of the north being so considerable, is very useful to the inhabitants, who are deprived of the sun's light during many months; as it makes the sun rise much earlier, and set much later to them, than it otherwise would.

About the year 1725, Mr. Flamsteed, the English astronomer royal, published his table computed from his own observations; and this was the one commonly used in England for many years afterwards.

Sir Isaac Newton also constructed one from theory, which was first published by Dr. Halley in the Philosophical Transactions, N°. 268, for 1721. He made the horizontal refraction 33° 45', whereas Mr. Flamsteed's was only 33° 20'.

But although the refraction might be determined within a few seconds at all altitudes by observation; yet, the law of its increase from the zenith to the horizon was a subject that occupied the principal mathematicians and astronomers for more than a century. Newton having discovered the general principles of attraction, found that the refraction was a consequence of this law of nature; and that it arose from the attraction of the atmosphere on the particles of light. On this principle the curve which a ray of light describes might be determined: since it is successively attracted
REFRACTION.

By different layers of the atmosphere, increasing in density as they approach the earth, and consequently, bending the ray more and more from the right line which it described in the vacuum previous to its reaching the atmosphere. There are many authors who have endeavoured to find from theory the curve described by this ray in its course, by the assumption of various hypotheses; but perfection, and our attempts to arrive at it, as is well observed by the elder Caffini in discoursing on this subject, are like the progres of certain curves and their asymptotes. The principal of these works on the subject are Bernouilli (Hydrodyn. 1738, p. 221.) Boechevich (Oper. tom. ii.); Bouguer (Prix de 1729. Memoires, 1739, p. 427: 1749, p. 75.); Caffini (Epist. ad Montanari, 1665.; Refractions ci Parallelo, &c. 1671. Mem. for 1714, and his Alr. vol. i. p. 11. Paris, 1746, in 2 vols. 4to.); Descartes (Dieptrique, 4to. Paris, 1637.; De la Grange (Nouveaux Memoires de Berlin, vol. iii.); Euler (Mem. de Berlin, 1754, tom. x.); Gregory (Astronomy, vol. i. p. 358. edit. of 1715, in 8vo.); Hodgson (Mathematics, vol. i. p. 367.; Fluxions, p. 133.); Huygens (Treatise de la Lumiere, p. 44. Dieptrique, 4to. 1703.); Kramp (Analyse des Refract. Alr. et Terres, 4to. Straffburg, 1799.; Lambert (Les Proprietes Remarquables de la Route de la Lumiere. A la Haye, 1759. Another edition in German, 1773.); La Place (Mechanique Celeste, vol. i. p. 231.); Mayer (Tables, 1770.); Newton (Principia, b. i. sect. 14.); Oriani (Epheb. de Milan. 1788.); Thomas Simpson (Mathematical Differations, 1743.); Brookes Taylor (Methodus Incrementorum, 4to. Lond. 1715.); Propof. 27. p. 108.); Heimius (Diffract. de Computo refractionum Alr. et Terres, 4to. Paris, 1740.); Tobias Mayer (De Refractionibus Alr. et Terres, 1781.); La Hire (Mem. de l'Acad. pour 1702, p. 52.); d'Alembert (Opuscula Mathematiques, tom. viii. p. 297.)

It was conjectured by many of the earlier writers, that the refraction was subject to variations depending upon the weather; but it then amounted to little more than a conjecture, on account of the indifferent manner in which astronomical instruments were divided.孔雀 found by meridian altitudes of the sun in 1669, that it was greater in winter than in summer. He found also that it was left by day than by night. In the observations given at the end of his journey to Uraniborg, to settle the latitude of that place, and its difference of longitude from Paris, for the purpose of comparing the observations of Tycho Brahe with those made at the Royal Observatory of Paris, he found the horizontal refraction for the first limb of the sun that made its appearance above the horizon there 33° 8', and for the second 32° 37'. So that in the interval of time that the sun was rising, the refraction was diminished 25 seconds by the warmth arising from the sun's presence.

A quadrant being also directed by him from the top of Mount Valerian towards the summit of the church of Notre Dame at Paris, he found the depression 25°; but the sun had scarce risen, when it was increased to 22°; exhalations being raised by the sun's presence, and the medium between Paris and Mount Valerian become more equal; whereas, before the sun rose, the air of Paris was more dense than that of Mount Valerian.

The density of the atmosphere being the immediate cause of the refraction, it was very natural to suppose that it must decrease as this density became less; whether by causes which diminished its weight, or by the expansion produced by heat; and, indeed, astronomers were not long after this, before they discovered that very sensible differences were occasioned by these circumstances.

But all the honour of introducing corrections on account of the variation of density in the atmosphere, as indicated by the barometer and thermometer, is due to Melch. Lowthorpe and Haukpee; the former of whom in 1698 proved by a very simple experiment, in the presence of the Royal Society, that the refractive power of air is directly proportional to its density: and the latter, by repeating and extending the same course of experiments in the year 1708, with the machinery pointed out by the former, found that the variations of refraction, depending on the barometer, are proportional to the alteration of height of the mercury in the tube: and by a series of these experiments, he furnished us with a table of the corrections which it is necessary to make on account of the changes of heat indicated by the thermometer. These experiments, although not quite conclusive on the subject, were yet made with as much accuracy and care as the nature of the machinery, and the state of experimental philosophy of that time, would admit. An example is also given, towards the end of his paper, on the mode of applying them to correct the refraction. By these, Haukpee found that a volume of air expressed by unity, when the thermometer was at 18° above zero, became, at 50° below, one-eighth more dense: or, which is the same thing, that the air lost one-eighth of its density, for an elevation of 18° of Fahrenheit's thermometer; which is exactly the difference of heat between melting ice and boiling water. But although this one-eighth, as will be shown hereafter, was too small; yet it laid the foundation for other experiments, since made by several philosophers, by which the quantity of expansion has been determined more accurately.

We have already shewn that the refraction near the pole is greater than in our climate; the degree of cold being more intense. It was also found to be less in the torrid zone, where the heat is greater than in Europe. Bouguer made a variety of observations at Peru, the result of which he has given us. In 1740, he came down into an island situated in the river of Emeralds, called isle of Ica, where he determined the refraction from 1° to 7° of altitude; and the table which he afterwards computed shows the refraction to be about one-eleventh less than in Europe. The horizontal refraction he found to be 27°; but at 6° of altitude it is 7° 40'; and at 35° 6', it is 4° 49'. Bouguer then gives a table for Quito, which is more elevated above the level of the sea. M. le Gentil found it greater at Pondicherry in India, although in the torrid zone.

The refraction diminishes when we are elevated above the level of the sea. Bouguer observed the quantity of it at Chimborazo, 2388 toises above the level of the sea, and he found in it the horizon only 108'. At the crofs of Pituchina, 2044 toises above the sea, he found it 20° 48'; at Quito, 1479 toises above the sea, 22° 50'; but at the level of the sea 27°. These observations, when combined with the theory, produced the following rule; viz. if we take the excess of 5158 toises above the elevation of the place, with regard to the level of the sea, the refraction will be as the square root of this excess. Thus the square root of 5158 toises above the elevation of the place, with regard to the level of the sea, is 7° 17'; the refraction will be 7° 17'; this observation, when united with the theory, produced the following rule; viz. if we take the excess of 5158 toises above the elevation of the place, with regard to the level of the sea, the refraction will be as the square root of this excess. Thus the square root of 5158 toises above the elevation of the place, with regard to the level of the sea, is 7° 17'; the refraction will be 7° 17'; this observation, when united with the theory, produced the following rule; viz. if we take the excess of 5158 toises above the elevation of the place, with regard to the level of the sea, the refraction will be as the square root of this excess. Thus the square root of 5158 toises above the elevation of the place, with regard to the level of the sea, is 7° 17'; the refraction will be 7° 17';
REFRACTION.

It is indeed rather extraordinary, that in a memoir published by Caffini de Thury, among those of the Academy for 1745, he attempted to reconcile a number of observations with each other, by considering the state of the thermometer only, without at all noticing that of the barometer; although at that time Haukbee's experiments had been published about 57 years.

He concludes his paper, as is very natural to suppose, without being able to make the observations agree; but does clearly appear that the French, indeed, the above-mentioned experiments by Haukbee till about the year 1746. It is also worthy of remark, that although the necessity of introducing corrections on account of the alterations of the barometer and thermometer were likewise shown to be absolutely necessary by Dr. Halley (Phil. Trans. Vol. 364.), and the circumstance mentioned, and in some degree admitted by Le Monnier (Hist. Célést.), yet it does not appear that he followed the advice of his illustrious contemporary, but merely endeavoured, as Caffini did, to reconcile his observations with the state of the thermometer at the time of making those observations, without taking the barometer into account.

It would be easy to notice the different opinions respecting both the terrestrial and the astronomic refraction, which are to be met with in the writings of various authors on the subject: and it would be equally useless to notice all the tables of its quantity given by them, some of which differ very much from others. It will be sufficient to mention those only who made some considerable advances towards obtaining it with greater accuracy.

The next of these in order was La Caille (Mem. de l'Ac. de Sc. 1755 p. 347.), who, in determining it certainly bellowed very great pains, by making and reducing an immense number of observations, and afterwards comparing them with others made at Greenwich by Dr. Bradley, at Göttingen by Mayer, at Bologna by Zanotti, and by La Lande, who was then at Berlin. From these it appeared that the refraction at 45° of altitude was 1.56; but this, as will hereafter be seen, was very great by some seconds. In his paper on the subject, which is divided into four parts, he proves, first, that the mean refractions are very nearly the same for the same apparent altitudes throughout the whole extent of the terrestrial zone; since those which were observed at Paris did not exceed those observed at the Cape of Good Hope but by 0.1 at most. In the second he determines the absolute quantity of the mean refraction for the apparent height of the pole at Paris, and gives the result of his observations with regard to the latitude of Paris and of the Cape of Good Hope. In the third he gives his table of mean refraction, and another of corrections depending upon the state of the barometer and thermometer; concluding with some reflections on its construction and use. In the fourth he compares his new table with the most celebrated of those that had before that time been in use among astronomers; and he then shows how it agrees with the observations of Bradley, Zanotti, and Mayer.

But by La Caille's memoir it appears, that previous to this time M. Mayer had formed and communicated to him a table of astronomic refractions which he computed by means of an algebraic formula, the coefficients of which he deduced from his own observations, and took into account the corrections relative to those of the barometer and thermometer. He found the alteration of refraction for a depression 145 lines in the barometer, the same as for a rise of 10° in the thermometer, and the variation for each degree of the latter, according to his table, of the mean refraction, which he adopted for 28 inches of the barometer, and 5° of the thermometer. This proportion takes place down to 30° of zenith distance. Mayer considered also that the mean refraction is the same for all parts of the earth; and that the only variation which takes place depends on the changes of the weight and temperature of the atmosphere.

La Caille, in comparing Mayer's table with observations, found that his correction for the thermometer was a little over-rated; and accordingly, for his new table, altered it 0.0006933 in each degree. And here it may be observed that La Caille did not correct his altitudes above 50° at Paris, and 30° at the Cape; first, because he only noted the barometer and thermometer in the night, when he observed stars below 30° of altitude. Secondly, because, that at 30° of altitude, where the mean refraction is about 0.1 minute, the variation which belongs to 10° of the thermometer only amounts to 3.5 seconds; a quantity about equal to the limits of the errors of observations made with an instrument of six feet.

The formula given by Euler (Mem. de l'Ac. de Berlin, 1754, p. 131.), appeared also about this time. It took into account the variation of the refraction depending upon the thermometer and barometer, but was certainly too complicated to be generally adopted. He shews, however, that in very different hypotheses the refraction will be sufficiently exact, if taken in the inverse ratio of the degrees of heat, when the star or planet is not too near the horizon, but the precise quantity of this ratio was unknown to him.

In this state the refraction stood when Dr. Bradley took the subject into consideration, and began to find its quantity from his own observations. The rule which he adopted, although a very elegant one, he neither lived to complete nor to perfect to the world; but it was published after his death by Dr. Maskelyne, (Pref. to 11th vol. of Obs. 1765, Phil. Trans. 1764 and 1787, p. 157. Reg. Tables, etc.), and has commonly been used in England up to the present time. He found the mean refraction at 35° of altitude 79°, and, that at all other altitudes, it was equal to 79° multiplied by the tangent of the zenith distance, diminished by three times the refraction. Then supposing the mean state of the atmosphere to be at 20° 6 inches of the barometer, and 50° of Fahrenheit's thermometer, he made the true or corrected refraction equal to 79° + (Z. D. + 3r) x barom. 29.6 - 350 + ther., where it is to be understood that the mass of air is supposed to increase in bulk for each degree of Fahrenheit's scale.

A variety of experiments has been made at various times to ascertain the increase in bulk or a quantity of air represented by unity for a certain number of degrees of rise of the thermometer. The following is the most of them;

| M. Bonne | 1.00 25777 |
| Bradley | 1.00 25000 |
| Dalton | 1.00 20701 |
| De Luc | 1.00 20858 |
| Fahrenheit | 1.00 25777 |
| Gay Lussac | 1.00 20868 |
| Groombridge | 1.00 21000 |
| Haukbee | 1.00 20603 |
| La Caille | 1.00 22222 |
| Mayer | 1.00 20444 |
| Shackburg | 1.00 22222 |

It is well understood that in the last, the mass of air is supposed to increase in bulk for each degree of Fahrenheit's scale.
The refraction deduced from Bradley's very neat and simple formula was, in a few years, adopted by nearly all the astronomers of eminence throughout Europe. The extreme facility with which it might be computed, and the corrections applied, whether from the formula itself, or from tables ready calculated for that purpose, was a powerful recommendation in its favour; but its near agreement with observation soon established it.

We must now, without entering further into detail of minor improvements, proceed at once to the chapter given by La Place on this subject, in his "Mécanique Celeste," vol. iv. p. 241, where he has drawn, from an investigation which we cannot undertake to exhibit in this place, the following general formula, for expressing the refraction for all angles of elevation above 12 decimal, or 10.8 sexageimal degrees, viz,

\[
\begin{align*}
\tan \psi & = \frac{a \cdot \tan \alpha}{0.76 (1 + 0.00375)} - 0.76 \cdot \frac{a}{\cos^2 \alpha} + \frac{1}{2} a \cdot \sin 1'' \cdot \frac{1}{(1 + 2 \cdot \cos^2 \alpha)} \cdot \tan \alpha \times \frac{1}{\cos^2 \alpha} + R
\end{align*}
\]

where all the quantities are known except \( \psi \) and \( a \); latter represents a constant coefficient; viz, \( a \) is the observed zenith distance under the barometric pre dreadful \( a \), in metres, and \( R \) the temperature of the centigrade thermometer, \( r \) being the refraction; all, therefore, that is required for determining \( \psi \) is the value of the unknown coefficient \( a \), which is to be drawn from observations on the circumpolar stars, in the following manner.

Let \( Z \) be the distance of one of these stars from the zenith, in its superior meridian passage; \( Z' \), this distance at the inferior meridian passage, observed from the same point of the terrestrial surface; \( r \) and \( r' \), the corresponding refractions. Now all the other quantities, except \( a \), being known, we may, for the sake of simplicity, put the above form for both passages under this form,

\[
\tan \psi = A a + B a', \quad r = A' a + B' a',
\]

where \( A, B, A', B' \), are all known quantities. Writing also \( Z, Z' \), for the observed zenith distances, the true zenith distance, \( D \), corrected for refraction, will be

\[
Z + A a + B a', \quad Z' + A' a + B' a',
\]

which are, therefore, now equal to each other; consequently, by addition, we have

\[
Z + Z' + (A + A') a + (B + B') a' = 2 D;
\]

in which all the quantities are known, except \( a \) and \( D \). But by repeating similar observations on other stars, and denoting by \( Z'', Z''' \), \( A'', A''' \), \( B'', B''' \), the similar quantities before represented by \( Z, Z' \), \( A, A' \), &c. also \( a \) and \( D \) remaining the same for all stars observed in the same place, we shall have the two equations:

\[
Z + Z' + (A + A') a + (B + B') a' = 2 D, \\
Z'' + Z''' + (A'' + A''') a + (B'' + B''') a' = 2 D;
\]

from which it is obvious, the constant coefficient \( a \) may be obtained by the usual methods of elimination.

In the above operation, however, we have supposed the polar distances of the fame star to be the same for its superior and inferior passage; whereas we know that, in consequence of the effect of precession, nutation, and aberration, this distance is constantly varying; and we ought, therefore, to introduce these variations into the above equation. But our object being merely to give a general view of the principles made use of for the determination of the co-efficient \( a \), we have not thought it necessary to enter fo intricately into the minutiae of the computation. It appears from the above, that the constant co-efficient \( a \) may be determined by means of four observations on two different circumpolar stars; and consequently, that every such set of observations ought to produce the same result, or the same value of \( a \). But now, in order to simplify our first formula, by taking \( p = 0.76 \) metres, and \( t = 6 \), this may be put under the form,

\[
r = a \tan Z \left( 1 - \frac{0.003754}{\cos^2 \alpha} \right) + \frac{1}{2} a \sin 1'' \cdot \frac{1}{(1 + 2 \cdot \cos^2 \alpha)} \cdot \tan \alpha \times \frac{1}{\cos^2 \alpha} + \tan Z;
\]

in which, substituting for \( \cos^2 \alpha \), its value \( \frac{1}{1 + \tan^2 \alpha} \), and the proper numerical value of \( a \), as above found, as also of \( \tan 1'' \), the whole is reduced to the following form, viz.

\[
r = 0.99918761 \cdot a \tan Z - 0.001105823 \cdot a \tan^2 Z;
\]

which latter form M. Biot has shown to be equivalent to

\[
r = 185^\circ 24. \tan Z - 3.25 r \text{ for the decimal division;} \\
r = 60^\circ 666 \cdot \tan Z - 3.25 r \text{ for the sexag asial division.}
\]

But the reduction of it to this form would occupy more space than can be allowed for this article. This last form is as simple as can be desired, from which the following rule in words may be deduced, viz. The refraction under the same barometric pressure, and the same degree of temperature, is proportional to the tangent of the apparent zenith distance of the star, diminished by \( \frac{3}{2} \) times the refraction.

It must be remarked, however, that the formula \( r = A \tan Z - (Z - 3.25 r) \), though it exhibits the law of refraction in as simple a form as can be desired, is not well adapted for calculation, in confluence of \( r \) entering on both sides of the equation; and astronomers have, therefore, given various other methods of rendering the above formula more commodious. In order to which, it is first put under the form,

\[
\tan nr = \tan^3 n R \tan (Z - nr);
\]

\( R \) representing the refraction, answering to \( Z = 90^\circ \). Let us now add successively to both sides of this equation, the quantities \( + \tan nr \tan^3 n R - \tan nr \tan^5 n R \), and we shall have,

\[
tan nr (1 + \tan^3 n R) = \tan^3 n R \tan (Z - nr) + \tan nr \tan (Z - nr - \tan nr) - \tan nr \tan (Z - nr - \tan nr) \tan nr.
\]

Now, dividing these equations, member by member, \( nr \) will be eliminated, and we obtain

\[
\frac{1 + \tan^3 n R}{1 - \tan^3 n R} = \tan (Z - nr) + \tan nr \tan (Z - nr) - \tan nr \tan (Z - nr - \tan nr). \tan nr
\]

whence we draw

\[
\tan (Z - 2nr) = \cot 2n R \tan Z.
\]

Now
REFRACTION.

Now Z and n, R being known, we may compute the second side of this equation; whence the arc \( Z - 2\, n\, R \) is known, and consequently \( 2\, n\, R \); which, divided by \( 2\, n \), will give \( n \), as required. But it may be found still more simply by the formula,

\[
\tan\, n\, R = \tan\, n\, R \tan\, \frac{1}{2}\, n;
\]

\( \tan\, n \) being found by means of the auxiliary equation,

\[
\tan\, n = \sin^2\, n\, R - \tan\, Z.
\]

On the principle above explained, the following table of refractions has been computed, agreeing with the temperature of \( +14^\circ \) on the centigrade thermometer, and under a pressure of 8.76 metres of the barometer; which is the same as \( 57.2 \) Fahrenheit, and \( 29.022 \) English inches. And for any other temperature and pressure, the corresponding corrections must be made as indicated in Tables II. and III.; which tables are computed by means of the general formula given in the preceding part of this article.

We had intended to give here a short abstract of a very interesting paper on this subject, published by Mr. Groombridge, in the Philosophical Transactions for 1812; but having already exceeded our usual limits, we can only refer the reader to the volume itself, where he will find several neat and useful formulæ.

Having thus given a sketch of the method of determining the quantity of astronomical refraction for all angles of elevation, and under various degrees of temperature and barometric pressure, let us add a few words on the subject of terrestrial or horizontal refraction; for the determination of which, the following method has been successfully practised in the English Trigonometrical Survey.

Let \( A, A' \) (Plate XIX. Astronomer, fig. 11) be two elevated places on the surface of the earth; \( B, D \), the intercepted arc of the earth's surface; \( C \), the centre of the earth; \( A' H', A' H' \), the horizontal lines at \( A, A' \), produced to meet the opposite vertical lines \( C H', C H \). Let \( \alpha, \alpha' \), represent the apparent places of the objects \( A, A' \); then is \( \alpha' A A' \) the refraction observed at \( A \), and \( \alpha A' A \) the refraction observed at \( A' \); and half the sum of these angles will be the horizontal refraction, if we assume it equal at each station.

Now an instrument being placed at each of these stations \( A, A' \), the reciprocal observations are made at the same instant of time, which is determined by means of signals or watches previously regulated for that purpose; that is, the observer at \( A \) takes the apparent depression of \( A' \), at the

fame moment that the other observer takes the apparent depression of \( A \). Then, in the quadrilateral \( A C A' \), the two angles \( A, A' \), are right angles, and consequently the angles \( A, A' \), are together equal to two right angles; but the three angles of the triangle \( A A' \), are together equal to two right angles; and consequently the angles \( A, A' \), are together equal to the angle \( C \), which is measured by the arc \( B D \). If, therefore, the sum of the two depressions \( H A' a, H' A a, \) be taken from the sum of the angles \( H A' A', H' A A' \), which is equivalent, from the angle \( C \), (which is known, because its measure \( B D \) is known,) the remainder is the sum of the two refractions. Hence this rule, “Take the sum of the two depressions from the measure of the intercepted terrestrial arc, half the remainder is the refraction.” If, by reason of the minutenesses of the contained arc \( B D \), one of the objects, instead of being depressed below the tangent \( A H' \), appears elevated, as suppose \( A \) to \( a' \), then the sum of the angles \( a' A A' \), and \( a A' A \), will be greater than the sum \( 1\, A A' + 1\, A' A \), or than \( C \), by the angle of elevation \( a' A A' \); but if from the former sum there be taken the depression \( H A' A \), there will remain the sum of the two refractions, so that in this case the rule becomes as follows: “Take the depression from the sum of the contained arc and elevation, and half the remainder is the refraction.”

The quantity of this terrestrial refraction is estimated by Dr. Maitkelyne at one-tenth of the distance of the object observed, expressed in degrees of a great circle. Whence, if the distance be \( 10,000 \) fathoms, its 10th part, \( 1,000 \) fathoms, is the 62nd part of a degree, or one minute, which, therefore, is the refraction in altitude of the object at that distance. But Le Gendre is induced, by several experiments, to allow only one-fourteenth part of the distance for the refraction in the altitude, so that on the distance of \( 10,000 \) fathoms, the 14th part of which is \( 714 \) fathoms, he allows only \( 44'' \) of terrestrial refraction, so many being contained in \( 714 \) fathoms. (See his Memoir on the Trigonometrical Operations.) Again, Delambre makes the quantity of terrestrial refraction to be one-twelfth part of the arc of distance. And the English measurers, from many very exact observations, determine the quantity of the medium refraction to be a twelfth part of the said distance. The mean of all these is about \( .085 \) of the intercepted arc, which is probably not very far from the truth; this quantity, however, it must be observed, is found to vary very considerably with the different states of the weather and atmosphere, from one-eleventh to one-eighteenth of the contained arc.

**Table**
### Table I. Of Refraction.

Barometer 29.922 Inches = 0.76 Metre; Thermometer Centigrade, 14°; Fahrenheit's, 57.2°; Reaumur's, 11°.2.

To
To observe the Refraction of a Star, &c. 1. Observe the meridian altitude of a star near the zenith; whence the latitude of the place where it is seen. If the star is near the meridian, the true declination of the star is easily found; it being near the horizon, the star is near the horizon, and its altitude and the time of day will give the true declination. 2. Observe the altitude of the same star in any other degree, and note the time by a pendulum. 3. For the given time of observation, from the declination of the star, compute its true altitude.

This being thus found less than the altitude observed, subtract the one from the other; and the remainder is the refraction for that moment, in that degree.

Refraction of Altitude, is an arc of a vertical circle, by which the altitude of a star is increased by the refraction.

Refraction of Declination, is an arc of a circle of declination, by which the declination of a star is increased or diminished by the refraction.

Refraction of Ascension and Declension, is an arc of the equator, by which the ascension and declension of a star, whether right or oblique, is increased or diminished by means of the refraction.

Refraction of Longitude, is an arc of the ecliptic, by which the longitude of a star is increased or diminished by means of the refraction.

Refraction of Latitude, is an arc of a circle of latitude, by which the latitude of a star is increased or diminished by means of refraction.

Refraction, in Commerce, is a term sometimes used by merchants, where there has been an oversight in an account, to the prejudice of a person; who thereupon demands restitution of so much, added or omitted by mistake.

You must make me a refraction of five pounds lost in your account. I will deduct or make you a refraction of 30. charged inadvertently in my bill.

REFRACTORY. See an explication of the term under Apyreous.

REFRAIN, Fr., in Musica. See an explication of the term under Apyreous.

Refrain, Span., a proverb; the burden of a song in that language, being usually tententious, and including some moral precept.

Refrangible, whatever is capable of being refracted. See Refrangibility.

Refrangibility of Light, the disposition of the rays to be refracted.

A greater or less refrangibility is a disposition to be more or less refracted, in passing at equal angles of incidence, into the same medium.

That the rays of light are differently refrangible, is the foundation of Sir Isaac Newton's whole theory of light and colours. The truth of the principle, which was inquired into and established by our great philosopher in the year 1666, will appear from the following experiments.

1. Let \( E G \) (Plate XIX. Optics, fig. 1.) represent the window-shutter of a dark room, and \( F \) a hole in it, through which the light is transmitted to the prism \( A B C \), which refracts it towards \( P T \), where it appears in an oblong form; its length being about five times greater than its breadth, and exhibiting the various colours of the rainbow. In fig. 2, \( a g b \) represents a second prism, which refracts the light back again to \( Q \), where the image is round; whereas, without the intervention of this second prism, the light would have proceeded to \( P T \); and, consequently, have been oblong, as before. In this experiment Sir Isaac Newton took care that the plane \( a g \) was placed exactly parallel to \( B C \), and also \( b g \) to \( A C \), that the rays might be equally refracted, though in contrary ways, by both prisms. He also observed, that both prisms must be placed very near to one another; for if their distance be so great, that the colours begin to appear in the light, before its incidence on the second prism, those colours will not be destroyed by the refraction of that prism.

2. Having placed one of two boards behind the prism at the window, so that the light might pass through a small hole made in it for the purpose, and fall on the other board at the distance of about twelve feet, a hole being made in it to admit the passage of the incident light, he then placed another prism behind the second board, so that the light which was transmitted through both the boards might pass through that also, and be again refracted before it arrived at the wall. This being done, he took the first prism in his hand, and turned it about its axis so much, as to make the several parts of the image, cast on the second board, successively to pass through the hole in it, that he might observe to what places on the wall the second prism would refract them; and he saw, by the change of those places, that the light tending to that end of the image, towards which the refraction of the first prism was made, did, in the second prism, suffer a refraction considerably greater than the light which tended to the other end. The true cause, therefore, of the length of that image was discovered to be no other, than that light is not similar or homogeneal, but that it consists of rays, some of which are more refrangible than others; so that without any difference in their incidence on the same medium, some of them shall be more refracted than others; and therefore, that according to their particular degrees of refrangibility, they will be transmitted through the prism to different parts of the opposite wall.

To make this capital experiment, which Sir Isaac Newton himself justly calls the experiment crucis, let \( S F \) (fig. 3.) represent a ray of the sun, which, after passing through a hole in the window-shutter \( F \), is received by the prism in \( A B C \), close behind which is placed a board \( D E \), with a hole in it at \( G \), to admit any of the rays after they have been separated by the prism; then \( d e \) will represent the other board, placed at a considerable distance from the former, with a hole in it \( g \), to receive any part of the light transmitted through the other board. Behind this second board is placed another prism, \( a b \), through which different rays of light, falling upon it in the very same place, and with precisely the same angle of incidence, will be refracted higher or lower, on the opposite wall \( M N \). This experiment was conducted with the utmost circumivation and accuracy; and it is observed, that neither the different magnitude of the hole in the window-shutter, nor the different thicknesses of the prism, at the place where the rays passed through it, nor the different inclinations of the prism to the horizon, nor the different matter of the prisms, made any sensible change in the length of the image.

3. In order farther to establish this famous hypothesis of the different refrangibility of the rays of light, he held a prism in a beam of the sun, which was transmitted into the room through a hole in the window-shutter, so that its axis might be perpendicular to that beam; and having turned the prism about its axis to make the image ascend and descend, and when it seemed to be stationary between these contrary motions, he fixed the prism so that the refractions of both sides might be equal to each other. In this situation he looked at the hole through the prism, and observed the length of its refracted image to be many times greater than its breadth: the most refracted part of it was violet, the least refracted red, the middle parts blue, green, and yellow, in order. The same thing happened when he removed the prism.
out of the fun’s light, and looked through it upon the hole shining by the light of the clouds beyond it.

Considering that if the image of the fun should be drawn into an oblong form, either by a dilatation of every ray, or by any other causal inequality of the refractions, the same oblong image would, by a second refraction, made sideways, be drawn out as much in breadth, he placed a second prism immediately after the first, in an oblique position with respect to it, that it might again refract the light of the beam of the fun’s light, which came to it through the first prism; so that in the first prism, the beam would be refracted upwards, and in the second sideway. But he found that the breadth of the image was not increased by the refraction of the second prism, but only its upper part, which in the first prism suffered the greatest refraction, and appeared violet and blue, did again, in the second prism, suffer a greater refraction, than the lower part of it, which was red and yellow, and this without any dilatation of the breadth of the image. Thus let S (fig. 4.) represent the fun, P the hole in the window, A B C the first prism, and D H the second. If Y represent the round image of the fun, made by a direct beam of light, when the prisms are taken away, P T will be the oblong image of the fun, made by the same beam passing through the first prism only, and p t will be the image made by the crofs refractions of both prisms together. Sometimes he placed a third prism after the second, and sometimes a fourth after the third; by all which the image might be often refracted sideway, but the rays which were more refracted than the rest in the first prism, were also more refracted in all the others, and that without any dilatation of the image sideway; and, therefore, those rays, on account of their coninuity of a greater refraction, he called the more refrangible ones. He obersved, in order to render the meaning of this experiment more evident, that all the rays, which are equally refrangible, fall upon a circle answering to the fun’s dife. Let, therefore, A G (fig. 5.) represent the circle which all the most refrangible rays, transmitted from the whole dife of the fun, would illuminate, and paint upon the opposite wall, if they were alone. Let E I. be the circle which all the least refrangell rays would, in like manner, illuminate, and paint, if they were alone, and let B H, C J, and D K, be the circles which so many intermediate kinds of rays would succesively paint upon the wall, if they were singly propagated from the fun, the rest being always intercepted, and conceive that there are other intermediate circles without number, which other innumerable intermediate kinds of rays would succesively paint upon the wall, if the fun should successively emit every kind by itself. Now since the fun emits rays of all these kinds at once, they must altogether illuminate and paint innumerable equal circles, of all which, being ranged according to their different degrees of refrangibility, the oblong image P T before described is composed.

Now if the fun’s circular image, Y, which is made by an unrefracted beam of light, was by any dilatation of the single rays, or by any other irregularity in the refraction of the first prism, converted into the oblong image P T, then ought every circle in the image to be in like manner drawn out into a similar oblong figure, contrary to the refult of this experiment.

He considered further, that by the breadth of the hole through which the light enters into the dark chamber, there is a penumbra made in the circumference of the image Y, which is also visible at the sides of the oblong images P T and p t. He, therefore, placed at that hole a len, or object-glafs of a telescope, which might call the image of the fun distinctly on Y, without any penumbra at all; and he found that the penumbra of the rectilinear sides of the oblong images P T and p t was also thereby taken away, so that they were as distinctly defined as the circumference of the first image Y.

There are some other circumstances attending this experiment, by which the conclusion drawn from it is made still more plain and convincing.

Let the second prism, D H, (fig. 6.) be placed not immediately after the first, but at some distance from it, so that the light from the first prism may fall upon it in the form of an oblong spectrum q r, parallel to this second prism, and may be refracted sideway, to form the oblong image, p t, upon the wall, and it will be found that this image, p t, is inclined to the image P T, which the first prism would have formed without the secon; the blue ends, P and p, being farther diftant from one another than the red ones, T and t; and, consequently, the rays which go to the blue ends, q, of the image q r, and which, therefore, suffer the greatest refraction in the first prism, are again, in the second prism, more refracted than the rest.

At two holes made near one another in his window-flutter, he placed two prisms, one at each, which might cast upon the opposite wall two oblong coloured images of the fun; and at a little distance from the wall he placed a long lencer paper, with straight and parallel edges; and he placed the prisms and papers, so that the red colour of one image, at 1, (fig. 7.) might fall directly upon one half of the paper, and the violet colour, M, of the other image, upon the other half of the same paper. Then with a black cloth he covered the wall behind the paper, that no light might be reflected from it to disturb the experiment; and viewing the paper through a third prism, held parallel to it, he saw that half of it which was illuminated by the violet light to be divided from the other half, by a greater refraction, especially when he retired to a considerable distance from the paper.

He further caused the two images, P T and M N (fig. 8.) to coincide, in an inverted order of their colours, the red end of each falling on the violet end of the other; and then viewing them through a prism D H, held parallel to their length, they no longer appeared coincident, as when they were viewed with the naked eye, but in the form of two distinct images, p t and M N, croffing one another in the middle; which shews that the red of the one image, and the violet of the other, which were coincident at P N and M T, being parted from one another by a greater refraction of the violet to p m, than that of the red to n t, differ in degree of refrangibility.

Having placed a prism, whose two angles at its base were equal to one another, and half right ones, and the third a right one, in a beam of the fun’s light, admitted into the room as before, he turned it slowly about its axis, till all the light which went through one of its angles, and was refracted by it, began to be reflected by its base, and by that means refracted, did first of all, by a total refraction, become more copious in that light than the red; and that afterwards the red, also, by a total refraction, became as copious as that. To try this, he made the reflected light pass through another prism, and being refracted by it, to fall afterwards upon a sheet of white paper, at some distance behind it, and there to paint the usual colours of the prism. Then causing the first prism to be turned about its axis, he observed, that when those rays which, in this prism, had suffered the greatest
greatest refraction, and were of a blue and violet colour, began to be wholly reflected, the blue and violet light on the paper, which received the rays from the second prism, was sensibly increased, above that of the red and yellow, which was least reflected; and afterwards, when the red of the light, which was green, yellow, and red, began to be wholly reflected in the first prism, the light of these colours on the paper received as great an increase as the violet and blue had done before. From this it is manifest, that the beam reflected by the bale of the prism, being augmented first by the more refrangible rays, and afterwards by the less refrangible ones, is compounded of rays differently refrangible. This experiment is illustrated by fig. 9, in which A B C represents the first prism, on the bale of which the light falls, at M. When this prism is turned about its axis, according to the order of the letters A B C, the more refrangible rays, M H, emerge more and more obliquely; and at length, after their mott oblique emergence, are reflected towards N, and going on to P, increase the number of rays N P. By continuing the motion of the first prism, the rays N P, are reflected to N, and increase the number of rays NP.

Since it appears from Sir Isaac Newton's experiments, that different rays of light have different degrees of refrangibility, it necessarily follows that the rules laid down by preceding philosophers, concerning the refractive power of water, glass, &c. must be limited to the middle kind of rays, as it may be supposed that Kepler, Snellius, and others would attend to them principally. Sir Isaac, however, proves that the sine of the incidence of every kind of light, considered apart, is to its sine of refraction in a given ratio. This he deduces both by experiment, and also geometrically, from the supposition that bodies reflect the light by acting upon its rays in lines perpendicular to their surfaces.

Upon the whole it appears, that the blue rays are more refracted than the red ones, and that there is, likewise, unequal refraction in the intermediate rays; and upon the whole it appears, that the sun's rays have not all the same refrangibility, and, consequently, are not of the same nature. It is also observed, that those rays which are most refrangible are also most refractible. See the proof of this under Reflexibility. Newton's Optics, p. 22, &c. ed. 3.

The difference between refrangibility and reflexibility was first discovered by Sir Isaac Newton, in 1671-2, and communicated in a letter to the Royal Society, dated February 6, 1671-2, and published in the Philosophical Transactions, N° 8, p. 3075; and from that time vindicated by him from the objections of several authors; particularly F. Pardies, M. Mariotte, Fr. Linus, and Lin, and other gentlemen at the English college at Liege; and at length it was more fully laid down, illustrated, and confirmed, by a great variety of experiments, in his excellent treatise of Optics.

But farther, as not only those colours of light produced by refraction in a prism, but also those reflected from opaque bodies, have their different degrees of refrangibility and reflexibility; and as a white light arises from a mixture of the several coloured rays, the fame great author concluded all homogeneous light to have its proper colour, corresponding to its degree of refrangibility, and not capable of being changed by any reflections, or any refractions: that the sun's light is compounded of all the primary colours; and that all compound colours arise from a mixture of the primary ones, &c.

The different degrees of refrangibility he conjectures to arise from the different magnitude of the particles of which the different rays consist. Thus the most refrangible rays, i.e. the red ones, he supposes to consist of the largest particles; the least refrangible, i.e. the violet rays, of the smallest particles; and the intermediate rays, yellow, green, and blue, of particles of intermediate sizes.

Having given a general view of the Newtonian theory of colours, as they depend upon the refraction of light, under the article Colour, we shall here add some farther particulars on this subject. From a review of that article, and of what has been above delivered, we may infer that, as the rays of light differ in refrangibility, they also differ in their disposition to exhibit this or that particular colour; so that colours are not modifications of light, derived from refractions or reflections of natural bodies, but original and connate properties, which are different in different rays. Moreover, to the fame degree of refrangibility always belongs the same colour, and to the same colour the same degree of refrangibility; nor are the same species of colour, and degree of refrangibility, that are proper to any particular kind of ray, susceptible of change by refraction and by reflection of natural bodies, nor by any other cause which Sir Isaac Newton could observe. Although a seeming transmutation of colours may be made by a mixture of different kinds of rays, yet, in such mixtures, the component colours themselves do not appear; but, by their mutually alloying each other, constitute a middle colour: and, therefore, if, by refraction, the different rays be separated, colours will emerge different from that of the composition. Thus blue and yellow powders, finely mixed, appear green to the naked eye; and yet the colours of the component particles are not thereby really changed, but only blended: for when they are viewed with a microscope, they still appear blue and yellow. It appears that there are also two sorts of colours: the one original and simple; the other compounded of these. The original and primary colours are red, orange, yellow, green, blue, indigo, and a violet purple, and an indefinite variety of intermediate gradations. The same colours in specie with those primary ones may be also produced by a composition: thus a mixture of yellow and blue makes green; of red and yellow, orange; and of orange and yellowish-green, yellow. In general, if any two colours are mixed, which, in the series of those that are produced by the prism, are not too far distant from one another, they, by their mutual alloy, compose that colour which appears in the midway between them; but those which are at too great distance have not this effect: e. g., orange and indigo do not produce the intermediate green, nor scarlet and green the intermediate yellow.

The most wonderful composition is that of white, which no one of these rays alone can exhibit, but which is always compounded; so that all the aforementioned primary colours, mixed in a certain proportion, are necessary to form it. See Colour.

Having given, in the preceding part of this article, the extremes of the different degrees of refrangibility in the different kinds of light, we shall now proceed to give the result of Newton's investigation, concerning the different degrees of refrangibility of all the different kinds of light, according to their several colours; particularizing this part of the subject with an explanation of the method which he made use of to define the boundaries of each colour, in the oblong image of the sun above described. In that image, though there was a manifest difference of colour, not only between the two extremes, but also in the intermediate parts, yet the exact place at which any one colour ended, and another began, was far from being sufficiently distinguishable.
guiltable. The reason of this indistinctness is, that rays of every kind coming from all parts of the sun's disc, an entire image of the sun is projected on the paper, confining of a circle of each particular colour; and as the rays differ in kind by infinitesimal degrees, from the extreme red to the extreme violet, there must, in fact, be thousands of these circles in the flame oblong image, the centres of which are infinitely near to one another; so that the light is intimately mixed, especially in the middle of the image, where it is the brightest.

If these circles, as he observes, whilst their centres keep their distances and positions, could be made less in diameter, their interfering one with another, and consequently the mixture of heterogeneous rays, would be proportionably diminished. Thus, in PT, (fig. 10.) the circles of which the solar image consists, expand into one another; but in the same figure, pt, being composed of less circles, but having their centres at the same distance as the former, do not extend into one another, the mixture being diminished in proportion to the diameters of the circles.

Now these circles would be diminished, if, without the room, at a great distance from the prism, towards the sun, some opaque body was placed, having a round hole in the middle of it, to intercept all the sun's light, excelling so much as, coming from the middle of its disc, could pass through that hole to the prism; for so the separate circles would no longer answer to the whole disc of the sun, but only to that part of it which can be seen from the prism, through that hole. But that these circles may answer more distinctly to the hole, a lens is to be placed by the prism, to cast the image of the hole, that is, of each separate circle, distinctly upon the paper; and if this be done, it will not be necessary to place that hole very far off, not even beyond the window. Instead, therefore, of that hole, he made use of the hole in his window-shutter, in the following manner.

At about 10 or 12 feet from the window, he placed a lens, by which the image of the hole might be distinctly cast upon a sheet of white paper, at the distance of 6, 8, 10, or 12 feet from the lens. Then, immediately after the lens, he placed a prism, by which the refracted light might be thrown upwards, or sideways; and he moved the paper that received it, either towards the prism, or from it, till he found the exact distance at which the images of the face appeared most distinct. By this means the circular images of the hole were terminated most distinctly, without any penumbra, and therefore extended into one another the least that they could; and consequently the mixture of the heterogeneous rays was the least of all. And by using a greater or less hole in the window-shutter, he made the circular images greater or less at pleasure, and thereby the mixture of rays in the oblong image was as much or as little as he chose. He sometimes made the breadth of the image 40 times, and sometimes 60 or 70 times less than its length. In this manner, he says, light is made sufficiently simple, and homogonous, for trying any of his experiments about simple light; for that the heterogeneous rays in this light are so few, as hardly to be perceived, excepting, perhaps, in the indigo and violet, which, being dark colours, do easily suffer a sensible alay by that little scattering light, which used to be refracted irregularly by the inequalities of the prism. The whole process of this experiment is so evident, by inspection of fig. 11, that it needs no particular illustration.

Instead of a circular hole, our author recommends a hole shaped like a long parallelogram, with its length parallel to the prism. For if this hole be an inch or two long, and but a 10th or 20th part of an inch broad, or narrower, the light of the image will be as simple as before, or more simple, and the image will become much broader, and therefore more fit for these experiments.

Or, instead of this hole, another may be formed of a triangle of equal sides, whose base may be about the 10th part of an inch, and its height an inch or more. For, by this means, if the base of the prism be parallel to the perpendicular of the triangle, the image $pt$ (fig. 20) will be formed of equicrural triangles, $ag$, $bh$, $eh$, $ed$, $eI$, $fm$, $cc$, and innumerable other intermediate ones, answering to the triangular hole in shape and bigness, and lying one another in a continual series, between two parallel lines, $ag$, $gm$. These triangles are a little intermingled at their bases, but not at their vertices; and therefore the light on the brighter side, $af$, of the image, where the bases of the triangles are, is a little compounded, but on the darker side, $gm$, it is altogether uncompounded; and in all places between the sides, the composition is proportionable to the diluences of the places from that oblique side $gm$. And having an image of such a composition, we may try experiments either in its stronger and less simple light, near the side $af$; or in its weaker and more simple light, near the other side $gm$, as shall seem most convenient.

In making these experiments, he advises, that the chamber be made very dark, that the lens be very good, being made of glass free from bubbles and veins, the sides of the prism truly plane, and its polished elaborately, with an angle of about 65 or 70 degrees; and the edges of the prism and lens, as far as they make any irregular refraction, should be covered with black paper glued on them. He also observes, that all the loose light should be intercepted with black paper, or other black obstructions. It being difficult to get glass prisms fit for these nice experiments, he sometimes used prismatic vessels made with pieces of broken looking-glasses, and filled with rain-water; and to increase the refraction, he sometimes strongly impregnated the water with fascorum sature.
between 77 and 78 be divided, as the line GM is divided by those intervals, there will be 77, 77, 77, 77, 77, 77, 77, 77, 78, for the lines of refraction of those rays out of glass into air, their common line of incidence being 50. So then the lines of the incidences of all the red-making rays out of glass into air were to the lines of their refractions not greater than 50 to 77, nor less than 50 to 77; but they varied from one another according to all their intermediate proportions, and of the other colours.

Having demonstrated that the light of the sun consists of a certain proportion of differently coloured light, our author proves, by another series of experiments, what has been already demonstrated by a single one mentioned above, that when a beam of light has been divided into its component parts, if they be again mixed, they will produce white; or if any one of them be intercepted, the image will appear tinged, and in a different manner, according to the different colours that are thereby prevented from mixing with the rest: and to complete the whole, he observes, that intercepting all the colours that compose the white image except one, and thereby making it to exhibit the appearance of all the colours in order; yet, if he made this succession of all the colours very quick, the appearance was always white, though it was demonstrable that only one colour took place at any one time; and he judiciously observes, that if each of these colours in succession give the idea of whiteness, much more will they produce that effect, when they are so intimately mixed as they are in a natural sun-beam.

Not content with composing whiteness from the separately coloured rays of the sun, he attempted, and succeeded in his attempt, to do the same with natural coloured bodies, observing the same proportions of the respective colours that he had found in the solar image. The coloured powders which he made use of at first produced only a kind of grey; but this was in fact a dull white, or whiteness mixed with shade: for when he contrived to throw a very strong light upon it, it became intensely white, so that a friend of his, who happened to call upon him while he was busy about these curious experiments, and who knew nothing of what he had been doing, pronounced that the powders he had been mixing, when thus illuminated, made a better white than some very fine white paper, with which he was comparing it.

As the preceding proportion of all the prismatic colours makes a white, it is evident that when they are mixed in different proportions, or when only a few of them are used, they will make different colours; and our philosopher has given us the following ingenious method of knowing, in a mixture of primary colours, the quantity and quality of each being given, the colour of the compound. With the centre O, (fig. 14.) and the radius OD, describe a circle ADF, and divide the circumference into seven parts, proportional to the seven musical tones or intervals contained in an octave, that is in proportion to the numbers $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, $\frac{1}{6}$, $\frac{1}{7}$. Let the first, DE, represent a red colour, the second, EF, orange, and so of the rest; and let all these colours be supposed to pass gradually into one another. Let $p$ be the centre of gravity of the arc DE, and $q$, $r$, $s$, $t$, $u$, $v$, $w$, $x$, be the centres of gravity of the other arcs; and about those centres let circles, proportional to the number of rays of each colour in the given mixture, be described. Then find a common centre of gravity of all those circles; and if a line be drawn from the centre of the circle O, through this point, as suppose $z$, the point $Y$, in which it terminates at the circumference, will show the colour that arises from the mixture; and the line OZ will be proportioned to the fullness or intemperance of the colour, the centre O representing perfect white. But if only two of the primary colours, which in this circle are opposite to one another, be mixed in an equal proportion, the point Z will fall upon the centre O, and yet the colour compounded of those two will not be perfectly white, but some faint anonymous colour; for he could never, by mixing only two primary colours, produce a perfect white. Whether it might be the result of three taken at equal distances in the circumference he could not tell; but he did not much question, that four or five of them would be sufficient. These, however, as he observes, are curiosities of little or no moment to the understanding of the phenomena of nature, since, in all natural whites, there is a mixture of all kinds of rays. Newton's Optics. Priestley's Hist. of Light and Colours.

For the method of correcting the effect of the different refrangibility of the rays of light in glasses, see Aberration and Telescope; see also Dispersion of Light.

Refrangibility of Radiant Heat. See Rays of Heat. Radiant heat, as well as light, is not only refrangible, but it is also subject to the laws of the dispersion, arising from its different refrangibility. The prism refracts radiant heat, so as to separate that which is less efficacious from that which is more so. The whole quantity of radiant heat contained in a sun beam, if this different refrangibility did not exist, must inevitably fall uniformly on a space equal to the area of the prism; and if radiant heat were not refrangible at all, it would fall upon an equal space, in the place where the shadow of the prism, when covered, may be seen. But neither of these events taking place, it is evident that the radiant heat is subject to the laws of refraction, and also to those of the different refrangibility of light. Whence Dr. Herchel is led to surmise, that radiant heat consists of particles of light of a certain range of momenta, which range may extend a little farther, on each side of refrangibility, than that of light. (See Rays of Heat.) Dr. Herchel having found that two degrees of heat were obtained from that part of the prismatic spectrum which contained the violet rays, while the full red colour, on the opposite side, gave no less than seven degrees, infers from these facts the different refrangibility of the rays which occasion heat, as clearly and certainly as it is concluded that the refrangibility of light is ascertained by the dispersion and variety of the colours. But he proceeds farther, and observes, that the rays of heat are of a much more extensive refrangibility than those of light. In order to make this appear, he delineates a spectrum of light, by assuming a line of a certain length; and, dividing it into seven parts, according to the dimensions assigned to the seven colours by sir Isaac Newton, in the fourth figure of the second part of his Optics, represents the illuminating power of which each colour is possessed, by an ordinate drawn to that line. And here, as the absolute length of the ordinates is arbitrary, provided they be proportional to each other, he assumes the length of that which is to express the maximum, equal to $\frac{1}{2}$ of the whole line.

Thus, let GQ (fig. 15.) represent the line that contains the arrangement of the colours, from the red to the violet. Then, erecting on the confines of the yellow and green line the line LR = $\frac{1}{2}$ of GQ, it will represent the power of illumination of the rays in that space. For, by experiments already delivered, we have shewn that the maximum of illumination is in the bright yellow or palest green rays. From the same experiments we collect, that the illuminations of yellow and green are equal to each other, and not much inferior to the maximum; this gives us the ordinates K and M. Then, by the rest of the same experiments, we obtain also the
the ordinates H, I, N, O, P, with sufficient accuracy for
the purpose here intended. All these being applied to the
middle of the spaces which belong to their respective
colours, we have the figure G R Q G, representing what may
be called the spectrum of illumination.

We are now, in the same manner, to find a figure to ex-
press the heating power of the refracted prismatic rays, or
what may be called the spectrum of heat. In order to de-
term the length of the base, Dr. Herschel examined the
extent of the invisible rays, and found, that at a distance of
two inches beyond visible red, his thermometer, in a few minutes,
acquired 1/4 degree of heat. The extent of the coloured
spectrum at that time, or the line which answered to G Q in
his figure, measured 2,997 inches. If two inches had been
the whole of the extent of the invisible part, it might be
stated in proportion to the visible one as 2 to 3; but we
are to make some allowance for a small space required
beyond the last ordinate, that the curve of the heating power
drawn through it may reach the base; and indeed, at 2½ inches
beyond visible red, Dr. Herschel could still find 1/4 degree
of heat. It appears therefore sufficiently safe, to admit
the base of the spectrum of heat A Q, to be that of the
spectrum of light G Q, as 5/2 to 2; or, conforming to the
Newtonian figure before mentioned, the base of which is
3.3 inches, as 57½ to 32. Now, if we assume for the
maximum of heat, an ordinate of an equal length with that
which was fixed upon for the maximum of light, it will give
us a method of comparing the two spectra together. Accord-
ingly, Dr. Herschel has drawn the several ordinates B, C, D,
E, F, G, H, I, K, L, M, N, O, P, of such lengths as,
from experiments made on purpose, it appeared they should
be, in order to express the heat indicated by the thermo-
meter, when placed on the base, at the several stations
pointed out by the letters. A mere inspection of the two figures, which have been
drawn as lying upon one another, will enable us now to see
how very differently the prism disperses the heat-making
rays, and those which occasion illumination, over the areas
A S Q A, and G R Q G, of our two spectra! These
rays neither agree in their mean refrangibility, nor in the
situation of their maximum. At R, where we have molt
light, there is but little heat: and at S, where we have
molt heat, we find no light at all!

REFRESHMENT, Quarterly of. See QUARTERS.

REFRET, Fr. the burden of a song. This word is only
to be found in the second folio edition of Bailey's
Dictionary, 1736. In no French dictionary is there au-
thority for it. Cotgrave, Dict. du Vieux Langage; Tre-
voux, Dict. de l'Académie; and Glossaries, have been con-
fulted in vain.

REFRIGERANT, Refrigerative, in Medicine, or
cooling, frigius, cold, an appellation given to such re-
medies as were supposed to cool the power of cooling the
internal parts. Hence all diuretics, such as ptisan, gruel, and
other thin drinks, vegetable and mineral acids, neutral
salts, and other substanstances, which are definite of stim-
ulating qualities, and communicate a sensation of coolness to
the tongue and throat, have been considered as refrigerant.
As they have no actual power of generating cold in the
animal body, the term is somewhat incorrect; but as it ex-
presses the opposite quality to that of stimulating, which is
used also as synonymous with heating, it is still retained, and
applied to diet, drink, and medicine of a non-stimulant qua-
In this sense, the term is nearly synonymous with fe-
dative.

Whatever, in fact, increaseth the circulation, increaseth the
heat of the body, and vice versa; potentially, therefore,
all sedative medicines may be said to be refrigerant. The
use of refrigerants will thence be inferred to be proper in
to other cases in which there is too much excitement of the
circulation, either locally or generally; such as local inflam-
ations, febrile diseases, hemorrhages, and the like. In
the case of external inflammations, indeed, actual re-
frigation may be produced, by the application of cold sub-
stanccs, water or ice, or by the ablation of heat by
means of evaporation; both of which afford the means of
directly diminishing the activity of the vessels of the part.
Thus, in burns and scalds, the pain is instantly relieved,
and the inflammation effectually reduced, by the immersion
of the part in cold water, if sufficiently perfused in. But
in respect to internal refrigerants, their operation is of a
negative kind, and consists rather in the removal of uneasy
sensations, and in the exclusion of stimulant substan-
stances, than in the actual suppression of increased action. See Se-
dative.

REFRIGERATION, denotes the act of cooling, or
the ablation of heat from various substances. This is
affected in a variety of ways, and for various purposes of
domestic use and of art; and the degree of cold that is
produced is estimated by an instrument called the thermo-
meter, which fee. Under this head it is needful to repeat
the principles of refrigeration, and the different processes
that are used for this purpose, which are amply stated and
described under the articles COLD, CONGELATION, COOLING,
FREEZING, HEAT, ICE, Ice-boxes, &c.

REFRIGERATORY, Refrigeratorium, in Che-
miftry, a copper vessel filled with cold water, rounded
the capital of an alembic, to cool and condense the vapours
raised thither by the fire, and to convert them into a liquor,
to be discharged thence through the beak. See ALEMBIC.
The water in the refrigeratory is to be changed from time
to time, as it begins to grow warm.

Sometimes they content themselves with wrapping a wet
cloth about the head of the alembic, instead of a re-
frigcator; but the more usual method now is, to supply the
place of the refrigeratory by a worm, or spiral pipe, run-
ning through a tub of cold water.

Distillation chiefly consists in evaporation and re-
frigcration. See DISTILLATION.

REFUGE, Refugium, in our Old Cufions, a san-
ctuary, or afoya; which see respectively.

At Paris there is an hospital called the Refuge, in which
dissolute women are shut up.

REFUGE, Cities of, in Scripture History, six cities
selected from the 48 appropriated to the residence of the
Levites, which were appointed for the protection of perfons from
the rigour of the law, who were chargeable with involuntary
homicide. Some have supposed that all the cities of the
Levites were asyla; but it appears from Numb. xxxv. 6.
that only six of them were appointed to this use. These
asyla were intended not only for Jews, but for Gentiles, or
for foreigners who dwelt among them. (Numb. xxxv. 15.)
They were not designed as sanctuaries for wilful murderers
and all sorts of atrocious villains among the Jews, as they
were among the Greeks and Romans, and as such places
have since been in Roman Catholic countries, but merely
for securing those who had been guilty of involuntary
homicide (Deut. xix. 4—10.) from the effects of private re-
venge, until they were cleared by a legal process. It is ob-
ervable, that the Israelites are commanded to "prepare the
way" that is, to make the road good, "that every flayer
may flee thither," without impediment, and with all ex-
pedition. (Deut. xix. 5.) By having good roads to them,
at least 32 cubits, or about 48 feet in breadth, and bridges
wherever
REG

wherever they were necessary, these cities were to be easy of access; and at crofs roads pofts were erected with inscriptions, directing the way to the "city of refuge." Upon this Hottinger remarks, that it was probably in allusion to this custom, that John the Baptif is described as "the voice of one crying in the wildernes, prepare ye the way of the Lord, make his paths ftraight." (Luke, iii. 4-6.) He was the Mediah's Forerunner, and in that character was to remove the obftacles to men's flying to him as their asylum, and obtaining peace from the violence of others. Every year, on the 15th of Adar, (February,) the magiftrates were to inspect the roads, and ascertain their good condition. These cities were to be supplied with water and provisions; but they were not to be the residence of any artifts who made weapons, by the use of which the relations of the defecrated might gratify their revenge. It was neceffary that those who took refuge in these places should understand some occupation, that might prevent their being chargeable, whilst they were waiting for their trial. In order to excite and maintain the greater horror even of involuntary bloodshed, the law punished it by a kind of banifhment, for the accused person was to remain in this city, without departing from it, till the death of the high-prieff, but after the high-prieff's death, he might safely go wherever he pleased.

REFUGEES, French Protestants, who, by the revocation of the edift of Nantes, in 1685, have been constrained to quit their country, and retire for refuge into Holland, Germany, England, &c. to fave themselves from the necessity of abandoning their religion.

REFUGIO, El, in Geography, a harbour in one of the islands of Mayorga, where Mauelle was supplied with water in 1784, and, by this, his fays, affords shelter from the moft furious winds. S. lat. 18° 30'. E. long. 177° 32'.

REFVINGE, a town of Sweden, in the province of Halland; nine miles N.N.W. of Helmitad.

REFUSAL, in Law, is where one hath by law a right and power of having or doing fomething of advantage to him, and he declines it. An executor may refuse an executorship; but the refufal ought to be before the ordinary; if an executor be summoned to accept or refufe the executorship, and he doth not appear upon the summons and prove the will, the court may grant administration, &c. which fhall be good in law till fuch executor hath proved the will; but no man can be compelled to take upon him the executorship, unlefs he hath intermeddled with the elfate. (1 Leon. 154. Cro. Eliz. 558.) Where there are feveral executors, and they all refufe, none of them fhall admifter afterwards; but if there is a refufal by one, and the other proves the will, the refufing executor may admifter when he will, during the life of his co-executor. (1 Rep. 28.) If there is but one executor, and he admifter, he cannot refufe afterwards; and if once he refufe, he cannot admifter afterwards.

There is a refufal of a clerk prefented to a church, for want of literature, &c. and if a bishop once refules a clerk for insufficiency, he cannot accept of him afterward, if a new clerk is prefented. (5 Rep. 58. Cro. Eliz. 27.) In a&ion of trover and conforvin, a demand of the goods, and refufal to deliver them must be proved. &c. 10 Rep. 56.

REFUTATION, Refutation, in Rhetorics, that part of the anwfer made to an opponent, which disproves what had been advanced by him.

REGA, in Geography, a river of Pomerania, which rifes three miles N.W. of Dramburg, paffes by Regenwalde, Platte, Grienfindorf, Treptow, &c., and then runs into the sea, 12 miles S.W. of Colberg.

Vol. XXIX.

REGAHE, a town of Egypt, on the left bank of the Nile: six miles N. of Athieh.

REGAL, REGALIS, or REGALIS, fomething belonging to a king. Regal is of the fame import with royal; the former being formed of the Latin rex; the other of the French rois, king.

REGAL, Fr., a musical term, which the Encyclopédie defines, "fifh, an ancient instrument composed of many ficks of fonorous wood of different lengths, forming a fcale, played upon by an ivory ball fattenfed to the end of a flick." This is exactly the description of the fliccado, faid to be invented by the brother of Bremmer, the late music-feller in the Strand, who published a book of inftructions for playing upon it.

"Regal is, fecdondly, a spinet organized, or rather a small organ of two or three stops placed under a keyd instrument, very common in Spain and Italy. In France this kind of instrument is called a poftif."

Craigin, an organ-builder in London about the middle of the last century, furnished organs of this kind to many harpsichords and spinets in a virginal form. Smetzler, when he first came hither from Strafburg, was employed by Shudi to organize his harpsichord.

But regal in all Roman Catholic countries is a portable organ ufed in processions, carried by one perfon and played by another. We have seen that use made of this kind of organ at Naples. The pipes are of reeds, for the lightnefs of carriage.

In the lift of Edward VI. and queen Elizabeth's musical establishments in the Sloane MSS. at the British Muzeum, among the instrument-makers, the regal-maker is allowed 20/ yearly. And in our own memory there was an office in the chapel royal under the title of "tuner of the regals," but it was abolished, and united to fome more useful officer in the chapel.

In the supplement to the folio Encyclopédie, we are told that the regal is a portable organ, which has no pipes, or at moft fuch as are very short, the tones being produced by reeds. This we believe to be the truth. The instrument is fometimes fo small as to be fet on a table.

REGAL Figb. See ROYAL Figb.

REGAL Suit. See Suit.

REGALE, in the French Jurifprudence, is a right belonging to the king over all benefices in that kingdom.

The regale confifts in enjoying the revenues of bishoprics, during the vacancy of their fees, and of preferving to the benefices dependent on them, which become vacant during that time, and till fuch a fuccefsor have taken the oath of fidelity, and have procured letters patent, to fecure him from the regale.

The enjoyment of the fruits of the fee is called the temporal regale; that of preferring the benefices, the spiritual regale.

Some refer the origin of the regale to the time of Clovis; and fay, the clergy granted this privilege to the king upon his defeating the Vifigoths; others allege, that pope Hadrian I. gratified Charlemagne with it, in a council held at Rome. It is obferved by others, that the regale was originally no more than a ward, or admiftration; and that the kings were only depositaries of the fruits of the vacant bishoprics; and appointed benefices to look to them during the vacancy.

It is added, that the kings of the first and second race never enjoyed any fuch privilege; and that it was only introduced in the twelfth century, in favour of infellitures.

Whatever was the origin of the regale, it occasioned a very
very important and warm debate between Lewis XIV. and Pope Innocent XI., which began about the year 1678, and was carried on with great animosity and contention for several years after. Lewis was defacous, that all the churches in his dominion should be subject to the regale. Innocent pretended, on the contrary, that his claim could not be granted with such universality; nor would he consent to any augmentation of the prerogative of this nature that had formerly been enjoyed by the kings of France. Lewis summoned, for settling this dispute, the famous assembly of thirty-five bishops, and as many deputies of the second order, which met at Paris in the year 1682, and which extended the regale to all the churches in France, without exception. In this convocation the ancient doctrine of the Gallican church, that declares the power of the pope to be merely spiritual, and also inferior to that of a general council, was drawn up in four propositions, which were solemnly adopted by the whole assembly, and were proposed to the whole body of the clergy, and to all the universities through the kingdom, as a sacred and inviolable rule of faith.

Regale, Regalia, a magnificent treat, or entertainment, given to ambassadors, or other persons of distinction, to entertain or do them honour.

In Italy it is usual at the arrival of any traveller of eminence, to send him a regale, that is, a present of fruits, sweetmeats, &c. by way of refreshment.

Regalia, in Law, the royal rights or prerogatives of a king.

There are reckoned by civilians to be six: 1. Power of judicature. 2. Power of life and death. 3. Power of war and peace. 4. Matterles goods, as waifs, esprays, &c. 5. Affidaments. 6. Minting of money.

Regalia is also used for the several parts of the apparatus of a coronation; as the crown, the sceptre with the cross, sceptre with the dove, St. Edward's staff, four heraldic swords, the globe, and the orb with the cross, &c. used at the coronation of our kings.

Regalia of the Church, are those rights and privileges which cathedrals, &c. enjoy by grants, and other concessions of kings.

Regalia is sometimes also used for the patrimony of a church; as, regalia Sancti Petri. And more particularly, for such lands and hereditaments as have been given by kings to the church.

These regalia, while in possession of the church, were subject to the same services as all other temporal inheritances; and after the death of the bishop they reverted to the king, till he invetered another with them; which, in the reigns of William the Conqueror, and some of his immediate successors, was frequently delayed, and as oft did the bishops make complaint of it, as appears from Malmbury, Neubrigentis, &c.

This last author says, that great complaint was made against Henry II. "Quod episcopatus vacantis, et praevenientia periciperet commoda, diu vacare voluit, et ecclesiastics potius urbibus applicanda in feum redigit." Regalia Faeces is used for the bishop's doing homage, or fealty, to the king, when he is invetered with the regalia. Thus Malmbury, in Anfelm: "Regalia pro more illius temporis faciens principi vii. kalend. Octobris Cantuarii adhexit."

Regalities. See Royalties.

Regan, in Geography, a town of Persia, in the province of Kerman, and district of Nurmanheer, on the frontier of Kerman to the east, which district is about 90 miles in length, and in breadth from 30 to 50. This district is bounded on the N. and S. by a range of mountains, thence to the S. being covered with snow during the greater part of the year. The soil is fertile, the district populous, and well watered by streams from the mountains, and the climate hot in the plain, but cold on the mountains. The Afghans were lately expelled from this district by the Persians, who invited different tribes of Balouches to occupy the deserted villages.

Regan is a neat little town, surrounded by a mud wall, within which the cattle of the inhabitants are driven every night for protection. The fort is quadrangular, the walls high and in good repair, and flanked with bastions, with one gate, conically guarded for preventing the entrance of strangers. The capital of Nurmanheer is Krock, which is the residence of the governor, and built in the same style as Regan, but larger, and surrounded by a deep ditch. Before the expulsion of the Afghans, a city, called Bumm, was considered as the frontier town of Persia in this quarter. This city is strongly fortified by a high mud wall, flanked with towers, surrounded by a deep and broad dry ditch, with one gate; and it has a bazar tolerably suppled with dates, milk, and fruit. The ruins of Bumm tell us that it was formerly of much greater extent than it is at present. The fountains are said to have thrown water to an amazing height, and the gardens, which appear to have been walled in, and adorned with elegant summer-houses, produce the most delicious pomegranates. Kinmeris; Geog. Memoir of the Persian Empire, 1813.

Regard of the Forest, the oversight, or inspection, of it; or the office and province of the registrar; which is, to go through the whole forest, and every bailiwick of it, before the holding of the feilions of the forest, or justice-feast, to see and enquire of the trespasses in it, and for the survey of dogs. A court for this purpose is to be held every third year. See Expedition, and Forest.

"Ad vivendum, ad inquirendum, ad certificandum, &c." See Regarder.

Regard is also used for the extent of the registrar's charge, i.e. for the whole forest; or all the ground that is parcel of it.

Regardant, in Heraldry, is underlaid of a lion, or other beast of prey, borne in a posture of looking behind him, with his face towards his tail.

Others apply it to a beaiff, which only shews the head, and some part of the neck, as moving from out of some division of the coat into another. He bears azure, three bendlets, or, in a chief, argent, charged with a lion regardant, gules.

Regardant Villain, or Regardant to the Manor, denotes an ancient servant or retainer to the lord; thus called, because charged to do all base services within the manor, to see the same freed of all filthy and loathsome things that might annoy it, &c. Coke upon Littleton, fol. 120.

Regardeur of a Forest, Regarder Forest, an ancient officer of the king's forest, whose business was every year, upon oath, to take a regard, i.e. to take a view of the forest limits; also to inquire of all offences and defaults committed by the foresters within the forest, and of all the concealments of them; and whether all the other officers did execute their respective duties or not.

Mainwood refers this institution to king Henry II., but Spelman thinks the name, at least, was given since; and that they were the same with those officers called cubs defuncti.
REGATTA is a name given at Venice to a kind of exhibition on the water, in which the gondoliers contend for superiority in the art of rowing their gondolas.

A splendid entertainment, under this appellation, was exhibited on the Thames in 1775.

REGAU, in Geography, a town of Austria; 12 miles W. of Steyr.

REGI INCONSULTO, in Lavo, is a priest elected by the king to the judges, not to proceed in a cause which may prejudice the king, until he is advised. A regi inconsulto may be awarded, not only for the party to the plea, but upon suggestion of a stranger, on cause shown that the plea may be prejudiced by the proceeding, &c.

REGI Querel Coram. See Querela.

REGEL, or Rigel, in Aftonomy, a fixed star of the first magnitude, in Orion's left foot.

REGELSBRUN, in Geography, a town of Bavaria; seven miles N. of Brugg.

REGEN, a river which rises on the borders of Bohemia, and runs into the Danube, near Ratibon.—Also, a town of Bavaria, on the above-named river; 40 miles E. of Ratibon.

REGENERATED TARTAR. See Tartar, Regenerated.

REGENERATION, in Theology, the act of being born again by a spiritual birth, or becoming a child of God: or it is that change of heart and life experienced by a person, who forakes a course of vice, and sincerely embraces a life of piety and virtue.

When an infant is converted, baptism is always administered as a sign of regeneration.

The term is also used to signify the change of state that takes place at the resurrection. Matt. xix. 28.

REGENSBURG, in Geography, a city of Switzerland, in the canton of Zürich, situated on a mountain, and surrounded with walls in the year 1687: it is the principal place of a bailiwick formerly subject to the duke of Austria; 6 miles E. of Baden.

REGENSBURG. See Ratibon.

REGENSTAFF, a town of Bavaria, in the principality of Neuburg; seven miles N. of Ratibon.

REGENSTEIN, a town of Weilphalia, in the bishopric of Halberstadt; seven miles W. of Quedlinburg.

REGENSTORF, or Old Regensburg, a bailiwick of Switzerland, in the canton of Zürich, which derives its name from that of an ancient castle, destroyed in 1443.

REGEN, or Regen, a person who governs a kingdom during the minority or absence or incapacity of a king.

In France, the queen-mother has the regency of the kingdom, under the title of queen-regent, while the king is a minor. Some have urged, that women, being incapable of succeeding to that crown, were incapable of the regency; but calumny has declared in their favor.

Regent is also used for a professor of arts and sciences, who holds a chair, or seat of pupils, in a college.

The foreign universities are generally composed of doctors, professors, and regents. Regent and scholar are relative terms. See Tutor.

Regent is generally restrained to the lower classes, as regent of rhetoric, regent of logic, &c.; these of philosophy are rather called professors.

REGENWALDE, in Geography, a town of Hinder Pomerania, on the Rega; 30 miles N.N.E. of Stargard. N. lat. 53° 49'; E. long. 15° 34'.

REGHERENDARIUS, among the Romans, an officer who subscribed and kept a register of all petitions presented to the prefect. Pituic. in voc.

REGESTOLA, in Ornithology, a name used by some authors for the magogas, or larger butcher-bird, a very small hawk, not exceeding the size of a common thrush, but very fierce and voracious. See Lanius Excludor.

REGETZ, in Geography, a town of Hungary; 18 miles S. of Cacchau.

REGGE, a river of Holland, which rises near Enschede, and after passing by Ghoor, Ryijen, &c. joins the Veelt near Ommens.

REGGIO, Pietro, in Biography, a native of Genoa, who seems to have been the first Italian who gave our country a taste for the vocal refinements of his country. Before his arrival here, he had been in Spain, Germany, Swed, and France. Besides refinements in florid song, he was much admired for his exquisite manner of accompanying himself on the lute. His first residence in England was at Oxford, where he published, in 1677, a small tract, entitled "A Treatise to sing well any song whatever." In 1684 his book of songs, in folio, the words chiefly from Cowley, appeared. We know not what were the taste and expression which rendered his vocal powers so captivating; but his airs are very dry and monotonous, and in as old an Italian taste as those of Lalli.

REGGIO, in Geography, a city of Italy, capital of the department of the Croftolo, and formerly of the duchy of Modena, the fee of a bishop, suffragan of Bologna. It was founded by the Tufcans, and became a Roman colony under Lepidus the triumvir. It was destroyed by Alaric, and rebuilt by Charlemagne. Its number of convents is 16, and of inhabitants about 18,000. The cathedral contains many capital pictures and sculptures. The inhabitants of this city were the first of all the Italians, who in 1794 renounced their allegiance to their own sovereign, Hercules III., who fled to Venice, afterwards took up arms, and solicited the protection of Bonaparte. He took possession of the city, proclaimed the liberty of the inhabitants, and instituted a legislative committee, who took the oath of allegiance to the French republic. Reggio is the native place of the poet Ariosto; 14 miles W.N.W. of Modena.

N. lat. 44° 41'; E. long. 16° 38'.

Reggio, a sea-port town of Naples, in Calabria Ultra, situated on the straits of Messina. The inhabitants carry on manufactures of stockings, gloves, and waistcoats of thread or silk. This place is the seat of an archbishop, founded by the patriarch of Constantinople, and contains two colleges and seven convents. The environs abound in oranges, citrons, mulberries, and grapes, with some fur-garments. This town was called by the Greeks Rhégion, derived according to Diodorus from the Greek word ῥέγος, to break or tear, because Sicily was torn from Italy, either by the sea or an earthquake. It is very ancient, founded as some say by Jocalurus, son of Εὐσλος, king of Lipari, who entertained Ulysses; or, according to others, by the Calcidians, who came hither from Euboea. The territory of the Rhégini was free and powerful, though sometimes governed by tyrants. In the Peloponnesian war they suffered much from their neighbours the Epizephyrian Locri, and were distracted by internal contentions. In the time of Dionysius the elder they were very powerful and asserted their liberty, refusing an alliance with that tyrant, who demanded a daughter of the city. When Pyrrhus, the son of the Romans, the latter sent a legion for the protection of Rhégium; but the soldiers murdered the citizens and seized the city. After the war the insurgents were taken by the Romans, and put to death for their treachery and cruelty. St. Paul, on his journey to Rome, passed through this city. In the year 1783 it was again totally destroyed.
REG

by an earthquake; 16 miles S.E. of Messina. N. lat. 38° 6'.
E. long. 16° 53'.
REGGIOLO, a town of Italy, in the department of the
Mecio; six miles E. of Guatalla.
REGHABILE, a town of Africa, in the country of
Wangara, situated on a lake. N. lat. 12° 47'. E. long.
18° 19'.
REGIA AQUA. See AQUA.
REGIA VITA. See VIA.
REGIA VILLA. See VILLA.
REGICIDE, REGIICA, a king-killer. The term is
also used for the act itself of murdering a king; of regis, king,
and cede, I stay.
Regicide is chiefly used with us in speaking of the persons
concerned in the trial, condemnation, and execution, of king
Charles I.
REGIFUGE, REGIFIGIUM, a feast held in ancient
Rome on the sixth of the calends of March, i.e. on the 24th
of February, in memory of the expulsion of their
kings, particularly of Tarquin’s flying out of Rome on that
day. Some will have the feast to bear this name from the
rex facrorum, king of the sacrificers, flying out of the comitia,
or place of assembly, as soon as the feast was over, in
imitation of the flight of Tarquin the Proud.
Some critics and antiquaries will have Regifugium the
fame with Fugula; others hold them to be different.
REGIMEN, in Medicine, from rego, I rule or govern,
a rule or course of living, with regard to eating, drinking,
clothing, and the like, accommodated to some disease, or
particular course of medicine which the patient is under,
or intended as a prevention of some threatening malady.
In many diseases, especially those of the acute or febrile
diseases, the regimen is often of equal, and sometimes of more
importance than medicine; and there can be no doubt that the
humblest of physicians, by the introduction of a hot regimen in
the treatment of febrile complaints, contributed to render
these diseases more severe and fatal; and that the substitu-
tion of a cool regimen has of late years very materially
diminished the danger and mortality of these maladies.
This change in medical practice has been, in fact, but a return
to nature, and to Hippocrates, who taught this simple, but
clear and rational principle, “contra trium in mediendur;”
remedies should be of an opposite nature to diseases: that
is to say, if the body is morbidly hot, cold is the remedy; if
it is cold, the application of heat is necessary; if there is
over-dilution, inflammation, or plethora, evacuation must
be resorted to; if dejection, we must supply nourishment:
if there is thirst, the remedy is the free use of drink, and so
forth. The clear intincts of nature (where they can be
distinguished) are commonly infallible guides, as to the
regimen to be pursued; but let not morbid habits and preju-
dices be mistaken for them. Thus in all fevers, small-pox,
measles, scarlet-fever, catarrh, typhus, and the plague
itself, the natural bias is for fresh air, coolness, light bed-
clothes, clean linen, cold drink, light and merely liquid
nourishment, in small quantities, or absolute abstinence,
quietness of mind and body, relief from noise, strong light,
and every species of excitement; and this is precisely the
regimen, which experience has proved to be most beneficial
in such diseases. Under the influence of such a regimen,
where proper medicines are also employed, every symptom
is rendered comparatively mild; the distress of the sick is
diminished, by the soothing of every morbid sensation; and
the derangements, which would otherwise ensue, or be ag-
graved, in the more vital organs, as in the brain, lungs,
and alimentary canal, are frequently altogether pre-
vented.

REG

It is sufficient to contrast the effects of the hot regimen,
in febrile diseases, to be convinced of the truth of these
observations. When a person affected with any species of
fever, is confined in a close and heated apartment, in which
the free circulation of air is prevented by closed doors and
windows, curtains, &c. and is kept at the same time under
a load of bed-clothes, and supplied with hot drinks, or even
cordials of vinous and fermented liquors, with the view of
inducing perspiration, the consequences are as follow.
The whole train of symptoms is aggravated. The heat of the
patient is raised considerably above the natural standard,
notwithstanding the profuse peripheries which are constantly
hating him; the pulse is excited to the highest febrile stan-
ard; the thirst becomes incessant to supply the unnatural
waste of fluids; the mouth and lips become parched and
burned; the head is in constant pain, with confusion of ideas,
preventing all sound sleep, and occasioning distressing dreams,
and at length delirium; the whole powers of the frame be-
come prostrate, with disposition to fainting, or being moved,
or on palting an evacuation by flood; and from this situa-
tion the recovery is extremely precarious. In cases of contagious
fever, such as small-pox, measles, scarlet-fever, &c., the
eruption is always greatly multiplied by this hot regimen,
and all the symptoms are changed to what has been called a
putrid type; the tongue, teeth, and lips, become coated
with a black, clammy, and immovable fur; purple spots
appear on the skin; and the whole dilate affirms the char-
acter of malignancy. There is one disease, indeed, which is
solely the result of this hot regimen, which has made a con-
 siderable figure in the writings of physicians, who never
dreamed that it was of their own creation; we allude to the
milky fever. See MILLARIA.

The above may perhaps be considered as the extreme of
the picture, which is scarcely ever to be seen in the present
day. But the greatest difficulty which a physician has even
now to overcome, in the majority of cases of feverish diseases,
is to counteract the tendency of nurses and parents to the
adoption of more or less of this pernicious system. The fa-
lutary chill must be taken away from all liquids, whether
used internally or externally; the cheering breeze is deemed
a death-bringing draught; and though the patient may die
from the severity of a malignant fever, he must on no account
run the slightest risk of catching cold; that is to say, the
possible occurrence of a slight fore-throat, or a running at
the nose, is to be avoided religiously, at the expense of ag-
gravating both the sufferings and the danger, under a more
formidable disease. The use of wine and cordials, in these
diseases, is now confined to the poor and ignorant, and it is
not to be hoped, that the other parts of the hot regimen will
not long be referred to, at least among the more intelligent
classes of society. See COLD as a remedy.

REGIMEN, in Chemistry and Alchemy, is the method of
ordering and conducting any thing, that it may answer its
intention.

Thus, regimen of fire is the method of making and ordering
fire, and the degrees of it.

REGIMEN of the WORK, that is, of the philosopher’s tone,
called the work of patience, is the rule and conduct to be
observed to obtain protection.

There are three things, they say, to be chiefly regarded
in the regimen of the work. The first, to administer a gentle
easy heat at the beginning of the coction.

The second, to continue this external heat according to the
feasibility of the work, always observing four feasons, as in
the common and astronomical year; the beginning being the
winter, the progress the spring, then summer, and lastly
autumn, which is the time of maturity and perfection of the
tone;
REGIMEN

... in all which the heat is to be augmented in proportion to the augmentation observed in nature.

It is to be added, that the work may not be begun in any season; but regard is to be had to the season of nature, lest the winter of the work be found in the summer of the year, &c. Which, however, is to be understood of the day in which the mercury is put in the ovum philosophicum, not of that when it is begun to be set at liberty from the prisons which nature had inclosed it in.

The third is, that in augmenting the fire, the augmentation be not of a whole degree at once, the spirits being unable to bear such violence; but a degree is to be divided into four parts, and one part is to be taken at a time.

All the operations of the first regimen are occult and invisible; in the second regimen comes speculation, which, they say, is the first sensible change, shewing itself by its black colour.

REGIMENT, or Government, in Grammar, is that part of syntax or construction, which regulates the mutual dependency of words, and the alterations which one part of speech occasions in another, with regard to its mood, tense, or case, and thus it differs from concord, or the agreement which one word has with another, in gender, number, case, or person. See Concord.

The regimen, or government, is entirely arbitrary, and differs in all languages; one language forming its regimen by cafes, as the Latin and Greeks; others by particles in lieu of them, as the English by of, to, &c. the French, Spaniards, and Italians, by de, a, en, &c.

There are, however, some general maxims which hold good in all languages; as, 1. That there is no nominative case in any sentence but has a reference to some verb, either expressed or understood. Sometimes, indeed, the infinitive mood, or part of a sentence, is put as the nominative case to the verb; as in English, "to see the sun is pleasant." These sentences, or clauses, thus constituting the subject of an affirmation, may be termed "nominative cases."

2. That there is no verb, except in the infinitive mood, or the participle, but has its nominative case, either expressed or understood. Indeed, in languages which have proper accusatives, as the Latin, before infinitives there is an accusative, not a nominative case; as Seio Petrum effe dominum. The nominative case is commonly placed before the verb; but sometimes it is put after the verb, if it is a simple tense; and between the auxiliary and the verb, or participle, if a compound tense.

3. Two or more nouns, &c. in the singular number, joined together by one or more connective conjunctions, expressed or understood, must have verbs, nouns, and pronouns, agreeing with them in the plural number. The conjunction disjunctive, however, has an effect contrary to that of the conjunction connective; for as the verb, noun, or pronoun, is referred to the preceding terms, taken separately, it must be in the singular.

4. A noun of multitude, or signifying many, may have a verb or pronoun agreeing with it, either of the singular or plural number; but not without regard to the import of the word, as conveying unity or plurality of idea. In the application of this rule, we ought to consider whether the term immediately suggests the idea of the number it represents, or whether it exhibits to the mind the idea of the whole as one thing. In the former case, the verb ought to be plural; in the latter, it ought to be singular.

5. Pronouns must always agree with their antecedents, and the nouns for which they stand, in gender and number.

6. The relative is the nominative case to the verb, when no nominative comes between it and the verb; but when a nominative comes between the relative and the verb, the relative is governed by some word in its own member of the sentence; e. g. "he who prefers me, to whom I owe my being, whom I am, and whom I serve, is eternal."

7. When the relative is preceded by two nominatives of different persons, the relative and verb may agree in person with either, according to the sense.

8. Every adjective, and every adjective pronoun, belongs to a substantive, expressed or understood. Adjective pronouns must agree in number with their substantives; nevertheless this rule admits of exceptions; e. g. the word means in the singular number, and the phrases "by this means," "by that means," are used by our best and most correct writers, viz. Bacon, Tillotson, Atterbury, Addison, Steele, Pope, &c. Campbell, in his "Philosophy of Rhetoric," has this remark on the subject before us: "No periphrases of taste will, I presume, venture so far to violate the proper usage, and consequently to shock the ears of the general reader, as to lay 'by this mean,' 'by that mean.'" Lowth and Johnson seem also to be against the use of means in the singular number. The distributive adjective pronouns, each, every, either, agree with the nouns, pronouns, and verbs of the singular number only. Adjectives are sometimes improperly applied as adverbs. An adjective pronoun, in the plural number, will sometimes properly associate with a singular noun. Although the adjective always relates to a substantive, it is, in many instances, put as if it were absolute, especially where the noun has been mentioned before, or is easily understood, though not expressed. Substantives are often used as adjectives in this case, the word for used is sometimes connected with the substantive to which it relates; sometimes connected with it by a hyphen; and sometimes joined to it, so as to make the two words coalesce. Sometimes the adjective becomes a substantive, and has another adjective joined to it. When an adjective has a preposition before it, the substantive being understood, it takes the nature of an adverb, and is considered as an adverb.

9. One substantive governs another, signifying a different thing, in the polleffive or genitive case; inasmuch as that case always expresses the possessor, which must be governed by the possessor; as, "my father's house," "the king's reward," &c. When the annexed substantive signifies the same thing as the first, and serves merely to explain or describe it, there is no variation of case; as "George, king of Great Britain, elector of Hanover, &c." Nouns thus circumscribed are said to be in apposition to each other; and nouns are not infrequently used in apposition to sentences, or clauses of sentences. This rule does not hold so completely in the modern as it does in the ancient languages; because the particles of de, &c. which are the proper signs of the genitive case, are frequently used as prepositions. (See GENITIVE.) Substantives govern pronouns as well as nouns in the polleffive case; as "every tree is known by its fruit." Sometimes a substantive in the genitive or polleffive case stands alone, the latter one by which it is governed being understood. The English genitive has often an unpleasant sound, so that we make more use of the particle of to express the same relation: and in some cases, we use both the genitive termination and the preposition of; as "it is a discovery of sir Isaac Newton's," but when this double genitive, as some grammarians call it, is not necessary to distinguish the sense, or, especially in a grave style, it is generally omitted. Except to prevent ambiguity, it seems to be allowable only in cases which purport the existence of a plurality of subjects or the same kind, as "a subject of the emperor's." But after all that can be said for the double genitive, as it is termed,
termed, it is the opinion of some grammarians, that it would be better to avoid the use of it altogether, and to give the sentiment another form of expression.

10. Active verbs govern the objective (or accumulative) case, as "Virtue rewards her followers." In English, the nominative case, denoting the subject, usually goes before the verb; and the objective case, denoting the object, follows the verb active; and it is this order that determines the case in nouns: as, "Alexander conquered the Persians;" but the pronoun having a proper form for each of those cases, it is sometimes, when it is in the objective case, placed before the verb; and when it is in the nominative case, follows the object and verb; as "saw him ignorantly worship, him declare I unto you." Verbs neuter do not act upon, or govern, nouns and pronouns. Part of a sentence, as well as a noun or pronoun, may be said to be in the objective case, or to be put objectively, governed by the active verb; and sentences or phrases under this circumstance may be termed "objective sentences or phrases." The verb to be, through all its variations, has the same case after it as that which next precedes it; so that this substantive verb has no government, or case, but serves, in all its forms, as a conductor to the two cases, inferring that the two cases which, in the construction of the sentence, are the next before and after it, must always be alike. Passive verbs which signify naming, and others of a similar nature, have the same case before and after them; as "he was called Caesar." It is evident also, that certain other neuter verbs, besides the verb to be, require the same case, whether it be the nominative or the objective, before and after them; such verbs are, to become, to wander, to go, to return, to appear, to die, to live, to look, to grow, to seem, to roam, and several others. The auxiliary let governs the objective case; as, "let him beware.

11. One verb governs another that follows it, or depends upon it, in the infinitive mood; as, "cease to do evil," "learn to do well," and the preposition to, though generally used before the latter verb, is sometimes properly omitted; as "I heard him say it," instead of "to say it." This irregularity extends only to active or neuter verbs: for many other verbs, when made passive, require the preposition to before the following verb; as "He was seen to go." The infinitive is frequently governed by adjectives, substantives, and participles; and this mood has much of the nature of a substantive, expressing the action itself; which the verb signifies, as the participle has the nature of an adjective, so that the infinitive mood does the office of a substantive in different cases, as in the nominative, "to play is pleasant," and in the objective, "boys love to play." The infinitive mood is often made absolute, or used independently on the rest of the sentence, supplying the place of the conjunction that with the potential mood, as "to confess the truth, I was in fault." The preposition to, signifying in order to, was anciently preceded by for, as "what went ye out for to see;" but the word for before the infinitive, is now, in almost every case, obsolete.

12. In the use of words and phrases which, with respect to time, relate to each other, a due regard to that relation should be observed. Thus, instead of saying, "the Lord hath given, and the Lord hath taken away," we should say, "the Lord gave, and the Lord hath taken away." To preserve consistency in the time of verbs, and allo of words and phrases, says Mr. L. Murray, in his excellent treatise on Grammar, we must recollect that, in the subjunctive mood, the present and the imperfect tenses often carry with them a future sense; and that the auxiliaries should and would, in the imperfect time, are used to express the present and future, as well as the past. With regard to verbs in the infinitive mood, says the same popular author, the practice of many writers, among whom are some of the most respectable, appears to be erroneous. They seem not to advert to the true principles which influence the different tenses of this mood. The following rules will, according to our author's judgment, be found perceptive and accurate. "All verbs expressive of hope, desire, intention, or command, must invariably be followed by the present, and not the perfect of the infinitive." Instead of the phrase, "the last week I intended to have written," though common, the infinitive being in the past time, as well as the verb which it follows, it ought to be, "the last week I intended to write:" for how long sooner it now is since I thought of writing, "to write" was then present to me, and must still be considered as present, when I bring back that time, and the thoughts of it. Some writers on grammar, however, maintain that the former sentence is correct and grammatical, because, as they affirm, it simply denotes the speaker's intention to be hereafter in possession of the finished action of writing; but this reasoning admits of the following answers, according to the statement of Mr. Murray. The phrase "to have written" is, in English grammar, the established past tense of the infinitive mood, and as incontrovertibly the past tense of the infinitive in English, as scripsisse is the past tense of the infinitive in Latin; nor can any writers be warranted in taking such liberties with the language, as to contradict its plainest rules, for the sake of supporting an hypothesis. Moreover, these writers might, on their own principles, and with equal propriety, contend, that the phrase "I intended having written," is proper and grammatical; but by admitting such violations of established grammatical distinctions, confusion would be introduced, the language would be disorganized, and the most eccentric syllables of grammar might be advanced, and plausibly supported. In short, says our author, the phrase "I intended to have written," appears to involve the following absurdity; "I intended to produce hereafter an action or event, which has been already completed." Some may hastily infer from the rule above stated, and from the near relation between the verbs to desire, and to wish, that the latter verb, like the former, must invariably be followed by the present of the infinitive. But when any one considers, that the act of desiring always refers to the future, and that the act of wishing refers sometimes to the past, as well as sometimes to the future, he will perceive the distinction between them, and that, consequently, the following modes of expression are strictly justifiable: "I wished that I had written sooner," "I wished to have written sooner;" and he will be perfectly satisfied, that the following phrases must be improper: "I declared that I had written sooner," "I desired to have written sooner." Mr. Murray, having considered and explained the special rule, respecting the government of verbs, expressive of hope, desire, intention, or command, proceeds to state and elucidate the general rule, on the subject of verbs in the infinitive mood. "This rule," he says, "is founded on the authority of Harris, Lowth, Campbell, Pickbourn, &c.; and we think, too, on the authority of reason and common sense. "When the action or event, signified by a verb in the infinitive mood, is contemporary or future, with respect to the verb to which it is chiefly related, the present of the infinitive is required; when it is not contemporary, nor future, the perfect of the infinitive is necessary," To comprehend and apply this rule, the student has only to consider, whether the infinitive verb refers to a time antecedent, contemporary, or future, with regard to the governing or related verb. When this simple point is ascertained, there will be no doubt in his mind, respecting the form
form which the infinitive verb should have. A few examples
may illustrate these positions. If I wish to signify, that I
rejoiced at a particular time, in recollecting the fight of a
friend, some time having intervened between the seeing and
the rejoicing, I should express myself thus: "I rejoiced to
have seen my friend." The seeing, in this case, was evidently
antecedent to the rejoicing; and therefore the verb which ex-
presses the former, must be in the perfect of the infinitive
mood. The same meaning may be expressed in a different
form: "I rejoiced that I had seen my friend;" or, "in
having seen my friend;" and the student may, in general, try
the propriety of a doubtful point of this nature, by con-
